The liquid viscosity is calculated by

$$\mu = \exp(\text{C1} + \text{C2}/T + \text{C3} \ln T + \text{C4}T^{\text{c5}})$$

where μ is the viscosity in Pa·s and T is the temperature in K. Viscosities are at either 1 atm or the vapor pressure, whichever is higher. All substances are listed by chemical family in Table 2-6 and by formula in Table 2-7.

Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AICHE and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source shold be cited as R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007).

The number of digits provided for values at T_{min} and T_{max} was chosen for uniformity of appearance and formatting; these do not represent the uncertainties of the physical quantities, but are the result of calculations from the standard thermophysical property formulations within a fixed format.

The vapor thermal conductivity is calculated by

$$k = \frac{C1 T^{C2}}{1 + C3/T + C4/T^2}$$

where k is the thermal conductivity in W/(m·K) and T is the temperature in K. Thermal conductivites are at either 1 atm or the vapor pressure, whichever is lower. All substances are listed by chemical family in Table 2-6 and by formula in Table 2-7.

Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AICHE and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source shold be cited as R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007) .

The number of digits provided for values at T_{min} and T_{max} was chosen for uniformity of appearance and formatting; these do not represent the uncertainties of the physical quantities, but are the result of calculations from the standard thermophysical property formulations within a fixed format.

The liquid thermal conductivity is calculated by

$$k = C1 + C2T + C3T^2 + C4T^3 + C5T^4.$$

where k is the thermal conductivity in W/(m·K) and T is the temperature in K. Thermal conductivites are at either 1 atm or the vapor pressure, whichever is higher. All substances are listed by chemical family in Table 2-6 and by formula in Table 2-7.

Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AICHE and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source should be cited as R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007).

The number of digits provided for values at T_{min} and T_{max} was chosen for uniformity of appearance and formatting; these do not represent the uncertainties of the physical quantities, but are the result of calculations from the standard thermophysical property formulations within a fixed format.

*An approximate interpolation scheme is to plot the logarithm of the viscosity or the thermal conductivity versus the logarithm of the absolute temperature. At 250 K the viscosity of gaseous argon is to be read as 1.95×10^{-5} Pa·s = 0.0000195 N·s/m^2.

TABLE 2-317 Lower and Upper Flammability Limits, Flash Point, and Autoignition Temperature for Selected Hydrocarbons

Compound	CAS no.	Formula	LFL	LFL rating	UFL	UFL rating	Flash point °C	Flash point rating	Autoignition T °C	Autoignition rating

LFL and UFL are lower and upper flammability limits respectively in volume percent fuel in air. Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AIChE, the DIPPR Environmental Safety Property Data and Estimations Steering Committee and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source should be cited as T. N. Rogers, D. A. Zei, R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007). Flammability limits are from B. Lewis and G. Von Elbe, *Combustion, Flames and Explosions of Gases*, New York: Harcourt Brace Jovanovich (1987). Flash point data are from N. I. Sax, *Dangerous Properties of Industrial Materials*, 6th ed., New York: Van Nostrand Reinhold (1984). Autoignition data are from I. Glassman, *Combustion*, 3d ed., New York: Academic Press (1996). The ratings reflect DIPPR® ESP's effort to provide a critical evaluation and quality assessment of each data point with 15 being the highest score possible. The rating is not directly correlated with the estimated experimental uncertainty.

TABLE 2-318 Viscosities of Liquids: Coordinates for Use with Fig. 2-32

Liquid	*X*	*Y*
Acetaldehyde	15.2	4.8
Acetic acid, 100%	12.1	14.2
Acetic acid, 70%	9.5	17.0
Acetic anhydride	12.7	12.8
Acetone, 100%	14.5	7.2
Acetone, 35%	7.9	15.0
Acetonitrile	14.4	7.4
Acrylic acid	12.3	13.9
Allyl alcohol	10.2	14.3
Allyl bromide	14.4	9.6
Allyl iodide	14.0	11.7
Ammonia, 100%	12.6	2.0
Ammonia, 26%	10.1	13.9
Amyl acetate	11.8	12.5
Amyl alcohol	7.5	18.4
Aniline	8.1	18.7
Anisole	12.3	13.5
Arsenic trichloride	13.9	14.5
Benzene	12.5	10.9
Brine, $CaCl_2$, 25%	6.6	15.9
Brine, NaCl, 25%	10.2	16.6
Bromine	14.2	13.2
Bromotoluene	20.0	15.9
Butyl acetate	12.3	11.0
Butyl acrylate	11.5	12.6
Butyl alcohol	8.6	17.2
Butyric acid	12.1	15.3
Carbon dioxide	11.6	0.3
Carbon disulfide	16.1	7.5
Carbon tetrachloride	12.7	13.1
Chlorobenzene	12.3	12.4
Chloroform	14.4	10.2
Chlorosulfonic acid	11.2	18.1
Chlorotoluene, ortho	13.0	13.3
Chlorotoluene, meta	13.3	12.5
Chlorotoluene, para	13.3	12.5
Cresol, meta	2.5	20.8
Cyclohexanol	2.9	24.3
Cyclohexane	9.8	12.9
Dibromomethane	12.7	15.8
Dichloroethane	13.2	12.2
Dichloromethane	14.6	8.9
Diethyl ketone	13.5	9.2
Diethyl oxalate	11.0	16.4
Diethylene glycol	5.0	24.7
Diphenyl	12.0	18.3
Dipropyl ether	13.2	8.6
Dipropyl oxalate	10.3	17.7
Ethyl acetate	13.7	9.1
Ethyl acrylate	12.7	10.4
Ethyl alcohol, 100%	10.5	13.8
Ethyl alcohol, 95%	9.8	14.3
Ethyl alcohol, 40%	6.5	16.6
Ethyl benzene	13.2	11.5
Ethyl bromide	14.5	8.1
2-Ethyl butyl acrylate	11.2	14.0
Ethyl chloride	14.8	6.0
Ethyl ether	14.5	5.3
Ethyl formate	14.2	8.4
2-Ethyl hexyl acrylate	9.0	15.0
Ethyl iodide	14.7	10.3
Ethyl propionate	13.2	9.9
Ethyl propyl ether	14.0	7.0
Ethyl sulfide	13.8	8.9
Ethylene bromide	11.9	15.7
Ethylene chloride	12.7	12.2
Ethylene glycol	6.0	23.6
Ethylidene chloride	14.1	8.7
Fluorobenzene	13.7	10.4
Formic acid	10.7	15.8
Freon-11	14.4	9.0
Freon-12	16.8	5.6
Freon-21	15.7	7.5
Freon-22	17.2	4.7
Freon-113	12.5	11.4
Glycerol, 100%	2.0	30.0
Glycerol, 50%	6.9	19.6
Heptane	14.1	8.4
Hexane	14.7	7.0
Hydrochloric acid, 31.5%	13.0	16.6
Iodobenzene	12.8	15.9
Isobutyl alcohol	7.1	18.0
Isobutyric acid	12.2	14.4
Isopropyl alcohol	8.2	16.0
Isopropyl bromide	14.1	9.2
Isopropyl chloride	13.9	7.1
Isopropyl iodide	13.7	11.2
Kerosene	10.2	16.9
Linseed oil, raw	7.5	27.2
Mercury	18.4	16.4
Methanol, 100%	12.4	10.5
Methanol, 90%	12.3	11.8
Methanol, 40%	7.8	15.5
Methyl acetate	14.2	8.2
Methyl acrylate	13.0	9.5
Methyl *i*-butyrate	12.3	9.7
Methyl *n*-butyrate	13.2	10.3
Methyl chloride	15.0	3.8
Methyl ethyl ketone	13.9	8.6
Methyl formate	14.2	7.5
Methyl iodide	14.3	9.3
Methyl propionate	13.5	9.0
Methyl propyl ketone	14.3	9.5
Methyl sulfide	15.3	6.4
Napthalene	7.9	18.1
Nitric acid, 95%	12.8	13.8
Nitric acid, 60%	10.8	17.0
Nitrobenzene	10.6	16.2
Nitrogen dioxide	12.9	8.6
Nitrotoluene	11.0	17.0
Octane	13.7	10.0
Octyl alcohol	6.6	21.1
Pentachloroethane	10.9	17.3
Pentane	14.9	5.2
Phenol	6.9	20.8
Phosphorus tribromide	13.8	16.7
Phosphorus trichloride	16.2	10.9
Propionic acid	12.8	13.8
Propyl acetate	13.1	10.3
Propyl alcohol	9.1	16.5
Propyl bromide	14.5	9.6
Propyl chloride	14.4	7.5
Propyl formate	13.1	9.7
Propyl iodide	14.1	11.6
Sodium	16.4	13.9
Sodium hydroxide, 50%	3.2	25.8
Stannic chloride	13.5	12.8
Succinonitrile	10.1	20.8
Sulfur dioxide	15.2	7.1
Sulfuric acid, 110%	7.2	27.4
Sulfuric acid, 100%	8.0	25.1
Sulfuric acid, 98%	7.0	24.8
Sulfuric acid, 60%	10.2	21.3
Sulfuryl chloride	15.2	12.4
Tetrachloroethane	11.9	15.7
Thiophene	13.2	11.0
Titanium tetrachloride	14.4	12.3
Toluene	13.7	10.4
Trichloroethylene	14.8	10.5
Triethylene glycol	4.7	24.8
Turpentine	11.5	14.9
Vinyl acetate	14.0	8.8
Vinyl toluene	13.4	12.0
Water	10.2	13.0
Xylene, ortho	13.5	12.1

*Compiled by P. E. Liley from tables of specific heat at constant pressure, thermal conductivity, and viscosity given in SI units for integral kelvin temperatures and pressures in bars by Vasserman. *Thermophysical Properties of Air and Its Components* and *Thermophysical Properties of Liquid Air and Its Components.* Nauka, Moscow, and in translated form by the National Bureau of Standards, Washington. The number of significant figures given above reflects the similar numbers appearing for the constituent properties in the source references. While reasonable agreement occurs for atmospheric pressure with some other works, the fragmentary data available for the saturated, etc., states show large deviations.

*Dashes indicate inaccessible states. Average uncertainty is about 20 percent. Values derived from formulations for thermal conductivity, specific heat at constant pressure, and viscosity contained in *Thermophysical Properties of Refrigerants.* American Society of Heating, Refrigerating and Air-Conditioning Engineers, New York, 1976. For further details see M. W. Johnson, M.S.M.E. thesis, Purdue University, West Lafayette, Ind., 1976.

In this table are a representative selection of diffusion coefficients. The subsection "Prediction and Correlation of Physical Properties" should be consulted for estimation techniques. As general references, the works by Hirschfelder, Curtiss, and Bird, *Molecular Theory of Gases and Liquids,* Wiley, New York, 1964; Chapman and Cowling, *The Mathematical Theory of Non-Uniform Gases,* Cambridge, New York, 1970; Reid and Sherwood, *The Properties of Gases and Liquids,* McGraw-Hill, New York, 1964; and Bretsznajder, *Prediction of Transport and Other Physical Properties of Fluids,* Pergamon, New York, 1971, may be found useful. The most exhaustive recent compilation for gases is by Mason and Marrero, *J. Phys. Chem. Ref. Data,* 1 (1972). Unfortunately, the Mason and Marrero work cites only equations and equation constants and not direct tabulations. For these, the Landolt-Börnstein series is suggested.

TABLE 2-325 Diffusivities in Liquids (25 °C)

Zirconium	100	110	59	42	38	34	25	23	22	21	21				

*Especially at low temperatures, the thermal conductivity can often be markedly reduced by even small traces of impurities. This table, for the highest-purity specimens available, should thus be used with caution in applications with commercial materials. From Perry, *Engineering Manual,* 3d ed., McGraw-Hill, New York, 1976. A more detailed table appears as Section 5.5.6 in the *Heat Exchanger Design Handbook,* Hemisphere Pub. Corp., Washington, DC, 1983.

†Parallel to basal plane.

‡Perpendicular to basal plane.

§Also known as Teflon, etc.

Urethane foam	70		1.05	0.03	0.36
Vermiculite	120		0.84	0.06	0.60

NOTE: Difficulties of accurately characterizing many of the specimens mean that many of the values presented here must be regarded as being of order of magnitude only. For some materials, actual measurement may be the only way to obtain data of the required accuracy. To convert kilograms per cubic meter to pounds per cubic foot, multiply by 0.062428; to convert kilojoules per kilogram-kelvin to British thermal units per pound-degree Fahrenheit, multiply by 0.23885.

PREDICTION AND CORRELATION OF PHYSICAL PROPERTIES*

INTRODUCTION

Physical property values, sufficiently accurate for many engineering applications, can be estimated in the absence of reliable experimental data. The purpose of this subsection is to provide a set of recommended prediction methods for general engineering use; it is not a comprehensive review, and many alternative methods are available in the literature. Methods recommended were selected on the basis of accuracy, generality, and, in most cases, simplicity. They generally correspond to the methods tested and given priority in the DIPPR® 801 database project.†

Properties included in this subsection are divided into 10 categories: (1) physical constants: critical properties, normal melting and boiling points, acentric factor, radius of gyration, and dipole moment; (2) vapor pressure: liquid and solid; (3) thermal properties: enthalpy and Gibbs' energy of formation and ideal gas entropy; (4) latent enthalpy: vaporization, fusion, and sublimation; (5) heat capacity: ideal gas, gas, liquid, and solid; (6) density: gas, liquid, and solid; (7) viscosity: gas and liquid; (8) thermal conductivity: gas and liquid; (9) surface tension; and (10) flammability properties: flash point, flammability limits, and autoignition temperature. Each of the 10 subsections provides a definition of the relevant properties and a description of one or more recommended prediction methods. Each description lists the type of method, its uncertainty, its limitations, and the expected uncertainty of the predicted value. A numerical example is also given to illustrate use of the method. For brevity, symbols used for physical properties and for variables and constants in the equations are defined under Nomenclature and are not generally defined after their use except where doing so clarifies usage. A list of equation and table numbers in which variables appear is included in the Nomenclature section for quick cross-referencing. Although emphasis is on pure-component properties, some mixture estimation techniques have been included for physical constants, density, viscosity, thermal conductivity, surface tension, and flammability. Correlation and estimation of properties that are inherently multicomponent (e.g., diffusion coefficients, mixture excess properties, activity coefficients, etc.) are treated elsewhere in the Handbook.

*Some material in this subsection has been retained from the corresponding subsection in the Seventh Edition, which was coauthored by Thomas E. Daubert and Evan Buck.

†The Design Institute for Physical Properties (DIPPR®) is an industrial consortium under the auspices of AIChE; Project 801, Evaluated Process Design Data, is a pure-component database of industrially important compounds.

UNITS

The International Metric System (SI) of units has been used throughout this subsection. Where possible, the estimation equations are set up in dimensionless groups. This makes transparent any conversion factors that should be applied to obtain the property in a desired set of units and eliminates the requirement of specific units for variables. For example, rather than use P_c as a variable with defined units, the dimensionless group P_c/ Pa is used. When a value for P_c expressed in any units (say, P_c = 6.53 MPa) is inserted into this group, the result is dimensionless with an explicit indication of conversion factors that must be included:

$$\frac{P_C}{\text{Pa}} = \frac{6.53\text{ MPa}}{\text{Pa}} = \left(\frac{6.53\text{ MPa}}{\text{Pa}}\right)\left(\frac{10^6\text{ Pa}}{\text{MPa}}\right) = 6.53 \times 10^6$$

Section 1 of this handbook should be used for appropriate unit conversion factors.

Nomenclature

Physical constants	Definition	Value
h	Planck's constant	6.626×10^{-34} J·s
k	Boltzmann's constant	1.3806×10^{-23} J/(molecule·K)
N_A	Avogadro's number	6.022×10^{26} molecule/kmol
R	Gas constant	8.3143 Pa·m³/(kmol·K)

Properties	Definition	Typical units
A, B, C	Molecular principal moments of inertia	kg·m²
$B, B(T)$	Second virial coefficient	m³/kmol
B_m	Second virial coefficient for a mixture	m³/kmol
C_P	Constant-pressure molar heat capacity	J/(kmol·K)
C_p^o	Ideal gas constant-pressure molar heat capacity	J/(kmol·K)
C_v	Constant-volume molar heat capacity	J/(kmol·K)
H_i	Enthalpy of compound i	J/kmol
k	Thermal conductivity	W/(m·K)
k_b	Thermal conductivity at T_b	W/(m·K)
LFL	Lower flammability limit	%
M	Molecular weight	kg/kmol
P	Pressure	Pa
P	Parachor	unitless
P_c	Critical pressure	Pa
P_r	Reduced pressure; $P_r = P/P_c$	unitless
P^*	Vapor pressure	Pa
P^*_{meas}	Measured vapor pressure value	Pa
P_r^*	Reduced vapor pressure; $P_r^* = P^*/P_c$	unitless
P_t^*	Vapor pressure at triple point	Pa
R_g	Radius of gyration	m
S^o	Ideal gas entropy	J/(kmol·K)
S^s	Standard state entropy	J/(kmol·K)
S_r	Rotational contribution to entropy	J/(kmol·K)
S_{vib}	Vibrational contribution to entropy	J/(kmol·K)
T	Temperature	K
T_b	Normal boiling point temperature	K
T_{br}	Reduced temperature at T_b; $T_{br} = T_b/T_c$	unitless
T_c	Critical temperature	K
T_m	Melting temperature	K
T_{meas}	T at which a dependent property was measured	K
T_r	Reduced temperature; $T_r = T/T_c$	unitless
T_t	Triple point temperature	K
UFL	Upper flammability limit	%
V	Molar volume	m³/kmol
V_m	Mixture molar volume	m³/kmol
V_r	Reduced volume; $V_r = ZT_r/P_r$	unitless
w_i	Mass fraction of component i	unitless
x_i	Mole fraction of component i	unitless
y_i	Mole fraction of component i in vapor phase	unitless
Z	Compressibility factor; $Z = PV/RT$	unitless
Z_c	Critical compressibility factor; $Z_c = P_cV_c/RT_c$	unitless
Z_i	Compressibility factor of reference fluid i	unitless
ΔG_f^o	Ideal gas standard Gibbs energy of formation	J/kmol
ΔG_f^s	Standard state Gibbs energy of formation	J/kmol
ΔH_f^o	Ideal gas standard enthalpy of formation	J/kmol
ΔH_f^s	Standard state enthalpy of formation	J/kmol
ΔH_{fus}	Enthalpy of fusion	J/kmol
ΔH_{rxn}	Enthalpy change per mole of reaction as written	J/kmol
ΔH_{sub}	Enthalpy of sublimation	J/kmol
ΔH_v	Enthalpy of vaporization	J/kmol
ΔS_f^s	Standard state entropy of formation	J/(kmol·K)
ΔS_f^o	Ideal gas entropy of formation	J/(kmol·K)
ΔS_{fus}	Latent entropy of fusion	J/(kmol·K)
ΔZ_v	Change in compressibility factor upon vaporization	unitless
ρ	Molar density; $\rho = V^{-1}$	kmol/m³
ρ_c	Critical molar density; $\rho_c = V_c^{-1}$	kmol/m³

Nomenclature (*Continued*)

Properties	Definition	Typical units
ρ_r	Reduced molar density; $\rho_r = \rho/\rho_c$	unitless
ω	Acentric factor	unitless
η	Viscosity	Pa·s
η^o	Viscosity at low pressure	Pa·s
σ	Surface tension	mN/m
σ_m	Surface tension of mixture	mN/m
τ	Complementary reduced temperature (= $1 - T_r$)	unitless
τ_b	Complementary reduced normal boiling temperature (= $1 - T_{br}$)	unitless
μ	Dipole moment	D
μ_r	Reduced dipole moment [defined in Eq. (2-62)]	unitless

Eq. variables	Definition	(Equations), [Tables]
a	EoS constant	(2-66), [2-354]
$a, b, c, \ldots$	GC values for C_p and η	(2-51), (2-52), (2-53), (2-97), [2-356]
a, b, c	Correlation coefficients	(2-21), (2-23)
a_i	GC values	(2-43), (2-97), [2-346, 2-356]
a, b	Terms in second virial correlation	(2-61)
a, b	Chickos correlation parameters	(2-39), (2-40), (2-41)
a_i, b_i, d_i	GC values for liquid C_p	(2-51), [2-348]
$\bar{a}\ \bar{\alpha}$	EoS constant for mixture	(2-76)
$A, B, C, \ldots$	Correlation constants/parameters	(2-2), (2-20), (2-22), (2-34), (2-36), (2-50), (2-65), (2-68), (2-83), (2-85), (2-87), (2-88), (2-95), (2-96), (2-101), above (2-114)
A	Factor in liquid k correlation	(2-108), [2-358]
A_i	Constants in C_p^o correlation	(2-45), (2-46)
b	EoS constant	(2-66), [2-354]
$b_i, c_i, \ldots$	Reference EoS constants	(2-65), [2-353]
$\underline{b}_i$	GC value for AIT	(2-124), [2-363, 2-364]
$\bar{b}$	EoS constant for mixture	(2-75)
$B^{(i)}$	Second virial expansion terms	(2-58), (2-59), (2-60), (2-61)
C	Number of components in mixture	(2-55), (2-72), (2-73), (2-74), (2-75), (2-76), (2-77), (2-80), (2-81), (2-82), (2-98), (2-113), (2-119)
C_i	GC values for T_b or η	(2-15), (2-87), [2-341, 2-355]
$C_{i,int}$	Sum of intramolecular group-group interactions	(2-16)
C_{ij}	Group-group intramolecular interaction pair	(2-16), [2-342]
$(C_p^o)_i$	GC values for ideal gas heat capacity	(2-49), [2-347]
Cs_j	Chickos: GC value for C—H group	(2-41), [2-344]
Ct_j	Chickos: GC value for functional group	(2-41), [2-345]
f_i	Halogen correction for ΔH_{sub} correlation	(2-43), [2-346]
$f^{(i)}$	Vapor pressure deviation function	(2-25)
F	Factor in surface tension equation	(2-116), (2-117)
G_{ij}	Adjustable mixture viscosity parameter	(2-98)
g_c^E	UNIFAC combinatorial excess Gibbs energy	(2-99)
g_r^E	UNIFAC residual excess Gibbs energy	(2-99)
h	Parameter in Riedel vapor pressure equation	following (2-24)
K	Parameter in Riedel vapor pressure equation	following (2-24)
LFL_i	GC contribution	(2-122), [2-361, 2-362]
n	Number of nonhydrogen atoms	(2-15)
n_A	Number of atoms in molecule	(2-1), (2-30), (2-31), (2-48)
n_E	Number of occurrnces of element E in compound	(2-54)
n_i	Number of occurrences of group i	(2-27), (2-43), (2-49), (2-51), (2-53), (2-87), (2-109), (2-115), (2-122), (2-123), (2-124)
n_f	Chickos: no. of different functional groups	(2-41)
n_s	Chickos: no. of different nonring or aromatic C—H groups bonded to functional groups	(2-41)
n_x	Total no. of halogen and H atoms attached to C and Si atoms for ΔH_{sub} correlation	(2-43)
N	Total number of groups in molecule	(2-12), (2-15) (2-16), (2-43), (2-49), (2-51), (2-53), (2-54), (2-87), (2-97), (2-109), (2-115)
N_C	Number of C atoms	(2-121)
Nf_i	Chickos: no. of functional groups of type i	(2-41)
Ng_i	Chickos: no. of C—H groups of type i bonded to other C atoms	(2-41)
N_H	Number of H atoms	(2-121)

Nomenclature (*Continued*)

Eq. variables	Definition	(Equations), [Tables]
N_{CR}	Chickos: no. of CH_2 groups in nonaromatic ring to form cyclic paraffin of same ring size	(2-40)
N_O	Chickos: Number of O atoms	(2-121)
N_R	Chickos: no. of nonaromatic rings	(2-40)
N_S	Chickos: Number of S atoms	(2-121)
Ns_i	Chickos: no. of C—H groups of type *i* bonded to at least one functional group	(2-41)
N_X	Number of halogen atoms	(2-121)
$\bar{P}_c$	Pseudocritical pressure for mixture	(2-73)
$P_{c,ij}$	Cross term in mixing rule	(2-79)
q	Rackett equation power for Z_c	(2-69), (2-70), (2-81)
q_i	UNIFAC molecular surface area	following (2-100)
Q_k	UNIFAC group surface area	following (2-100)
r_i	UNIFAC molecular volume	following (2-100)
r^*	Dimensionless separation distance	(2-4)
R_k	UNIFAC group volume	following (2-100)
$(S^o)_i$	GC value for entropy	(2-27), [2-343]
t	Chickos: total no. of functional groups	(2-41)
$t_{m1,i}$	First-order GC contribution for T_m	(2-13), [2-339]
$t_{m2,i}$	Second-order GC contribution for T_m	(2-13), [2-340]
$\bar{T}_c$	Pseudocritical temperature for mixture	(2-72), (2-73), (2-80)
$T_{c,ij}$	Cross term in mixing rule	(2-78), (2-80)
x_P	Term in Pailhes method = log(1 atm/*P*)	(2-14)
U^*	Dimensionless intermolecular potential	(2-4)
UFL_i	GC contribution	(2-123), [2-361, 2-362]
$V_{c,ij}$	Cross term in mixing rule	(2-78), (2-79)
$Z^{(0)}$	Compressibility factor of simple fluid	(2-63), (2-64), [2-351]
$Z^{(1)}$	Acentric deviation term for *Z*	(2-63), (2-64), [2-352]
$Z_{c,ij}$	Cross term in mixing rule	(2-78), (2-79)
Z_{RA}	Modified Rackett correlation parameter	(2-70)
$\bar{Z}_{RA}$	Modified Rackett parameter for mixture	(2-82)
α, β, γ, . . .	Correlation parameters for *k*	(2-106), (2-107), (2-108), (2-109), [2-358]
$\alpha(T_r)$	EoS temperature-dependent function	(2-66), [2-354]
α_c	Parameter in Riedel vapor pressure equation	following (2-24)
α_{mn}	Viscosity group-group interactions	(2-100), [2-357]
β	Reference EoS constant	(2-65), [2-353]
β	Stoichiometric coefficient in FP correlation	(2-120), (2-121)
β_i	Nonlinear correction term in correlation	(2-43), (2-53), [2-346, 2-349]
γ	Reference EoS constant	(2-65), [2-353]
δ	= 0 for nonlinear molecules; = 1 for linear	(2-1), (2-48)
δ	EoS parameter	(2-66), [2-354]
Δ_E	Contribution of element *E* to heat capacity	(2-54), [2-350]
Δ_P	GC contribution to P_c	(2-7), (2-10), [2-336, 2-337]
Δ_T	GC contribution to T_c	(2-6), (2-9), [2-336, 2-337]
Δ_V	GC contribution to V_c	(2-8), (2-11), [2-336, 2-337]
$(\Delta H_f^o)_i$	GC value for enthalpy of formation	(2-27), [2-343]
Δk_i	GC for thermal conductivity at T_b	(2-109), [2-359]
$\Delta \mathbf{P}_i$	GC for parachor	(2-115), [2-360]
Δs_i	Chickos: GC value for group *i*	(2-41), [2-344, 2-345]
ε	Lennard-Jones well depth parameter	following (2-4)
ε	EoS parameter	(2-66), [2-354]
φ	UNIFAC molecular volume fraction	following (2-100)
ϕ_i	Volume fraction of component *i*	(2-80), following (2-100), (2-113)
ν_i	Stoichiometric coefficient (+ for product and − for reactant) for compound *i* in reaction	(2-28), (2-29), (2-30)
ν_j	Frequency of vibrational mode *j*	(2-47)
θ	UNIFAC molecular surface fraction	following (2-100)
Θ	UNIFAC group surface fraction	following (2-100)
Θ_A, Θ_B, Θ_C	Characteristic rotational *T* of molecule	before and following (2-31)
Θ*j*	Characteristic vibrational *T* of mode *j*	(2-1), (2-31), (2-48)
σ	Lennard-Jones size parameter	(2-4)
σ	Rotational external symmetry number	following (2-31)
μ_r^*	Modified reduced dipole moment	(2-85), (2-86)
ψ	Parameter in Riedel vapor pressure equation	following (2-24)
Ψ	Parameter in correlation of *k* for gases	(2-106)
Ψ_{mn}	UNIFAC interaction factor	(2-100)
ξ	Viscosity dedimensionalizing factor	(2-89), (2-90), (2-91), (2-92), (2-93), (2-94)
$\bar{\omega}$	Pseudoacentric factor for mixture	(2-74)
ω_{ij}	Cross term in mixing rule	(2-79)

CLASSIFICATION OF ESTIMATION METHODS

Physical property estimation methods may be classified into six general areas: (1) theory and empirical extension of theory, (2) corresponding states, (3) group contributions, (4) computational chemistry, (5) empirical and quantitative structure property relations (QSPR) correlations, and (6) molecular simulation. A quick overview of each class is given below to provide context for the methods and to define the general assumptions, accuracies, and limitations inherent in each.

Theory and Empirical Extension of Theory Methods based on theory generally provide better extrapolation capability than empirical fits of experimental data. Assumptions required to simplify the theory to a manageable equation suggest accuracy limitations and possible improvements, if necessary. For example, the ideal gas isobaric heat capacity, rigorously obtained from statistical mechanics under the assumption of independent harmonic vibrational modes, is [Rowley, R. L., *Statistical Mechanics for Thermophysical Property Calculations*, Prentice-Hall, Englewood Cliffs, N.J., 1994]

$$\frac{C_P^o}{R} = \frac{8-\delta}{2} + \sum_{j=1}^{3n_A-6+\delta} \left(\frac{\Theta_j}{T}\right)^2 \frac{e^{\Theta_j/T}}{(e^{\Theta_j/T}-1)^2}$$

$$\delta = \begin{cases} 0 & \text{nonlinear molecules} \\ 1 & \text{linear molecules} \end{cases} \tag{2-1}$$

where Θ_j is the characteristic temperature for the jth vibrational frequency in a molecule of n_A atoms. The temperature dependence of this equation is exact to the extent that the frequencies are harmonic. Corrections for anharmonicity can be applied (albeit with difficulty) where warranted.

Extension of theory often requires introduction of empirical models and parameters in lieu of terms that cannot be rigorously calculated. Good accuracy is expected in the region where the model parameters were fitted to experimental data, but only limited accuracy when an empirical model is extrapolated to other conditions. For example, a simplified theory suggests that vapor pressure should have the form

$$\ln P^* = A - \frac{B}{T} \tag{2-2}$$

where the empirical parameter B is given by

$$B = \frac{\Delta H_v}{R\Delta Z_v} \tag{2-3}$$

and ΔH_v and ΔZ_v are differences between the vapor and liquid enthalpies and compressibility factors, respectively. Vapor pressures over a narrow temperature range can be effectively correlated using Eq. (2-2), but this equation should not be used to extrapolate vapor pressures over a wide range of temperatures.

Corresponding States (CS) The principle of CS applies to conformal fluids [Leland, T. L., Jr., and P. S. Chappelear, *Ind. Eng. Chem.,* **60** (1968): 15]. Two fluids are conformal if their intermolecular interactions are equivalent when scaled in dimensionless form. For example, the Lennard-Jones (LJ) intermolecular pair potential energy U can be written in dimensionless form as

$$U^* = 4[(r^{*-12} - r^{*-6})] \tag{2-4}$$

where $r^* = r/\sigma$, $U^* = U/\varepsilon$, σ is the LJ size parameter, and ε is the LJ attractive well depth parameter. At equivalent scaled temperatures kT/ε (k is Boltzmann's constant) and pressures $P\sigma^3/\varepsilon$, all LJ fluids will have identical dimensionless properties because the molecules interact through the identical scaled intermolecular potential given by Eq. (2-4). Generalization of this scaling principle is commonly done using critical temperature T_c and critical pressure P_c as scaling factors. At the same reduced coordinates ($T_r = T/T_c$ and $P_r = P/P_c$) all conformal fluids will have the same dimensionless properties; for example, $Z = Z(T_r, P_r)$ where the compressibility factor is defined as $Z = PV/RT$. A correlation of experimental data for one fluid can be used as the reference for the properties of all conformal fluids. Nonconformality is the main accuracy limitation. For instance, interactions between nonspherical or polar molecules may not be adequately represented by Eq. (2-4), and so the scaled properties of these fluids will not conform to those of a fluid with interactions well represented by Eq. (2-4). A correction for nonconformality is usually made by the addition of one or more reference fluids whose deviations from the first reference fluid are used to characterize the effect of nonconformality. For example, in the Lee-Kesler method [Lee, B. I., and M. G. Kesler, *AIChE J.,* **21** (1975): 510] n-octane is used as a second, nonspherical reference fluid, and deviations of n-octane scaled properties from those of the spherical reference fluid at equivalent reduced conditions are assumed to be a linear function of the acentric factor. An extended Lee-Kesler method [Wilding, W. V., and R. L. Rowley, *Int. J. Thermophys.,* **7** (1986): 525] uses three reference fluids: n-octane to correct for size-shape nonconformality relative to methane and water to correct for polar effects. Some CS methods [e.g., Teja, A., S. I. Sandler, and N. C. Patel, *Chem. Eng. J.,* **21** (1981): 21] utilize different reference fluids for different classes of fluids to maintain close conformality between the fluid whose properties are to be estimated and the reference fluids.

Group Contributions (GC) Chemical and physical properties generally correlate well with molecular structure. GC methods assume a summative behavior of the structural groups of the constituent molecules. For example, ethanol (CH_3—CH_2—OH) properties would be obtained as the sum of contributions from the —CH_3,—CH_2, and —OH groups. The contribution of each group is obtained by regression of experimental data that include as many different compounds containing that group as possible. Structural groups must be used exactly as defined in the original correlation. A general priniciple in deciding how to make the groupings is to give the more specific group priority. For example, although the structural piece —$COOCH_3$ is ambiguous in a methyl ester, a more specific group value available for an ester —COO— would take precedence over a combination the two smaller groups —(C═O)— and

—O— whose values were most likely regressed only from ketone and ether data, respectively. Excellent accuracy can usually be expected from GC methods when group values were regressed from large quantities of experimental data. However, if the ratio of number of groups to regressed experimental data is large, significant errors can result when the method is applied to new compounds (extrapolation). Such excessive specificity in the group definitions leads to poor extrapolation capabilities even though the fit of the regressed data may be excellent.

Computational Chemistry (CC) Commercial software is available that solves the Schrödinger equation for approximate forms of the wave function. Various levels of sophistication (termed *model chemistry*) for the wave function can be chosen at the expense of computational time. Results include structural information (bond lengths, bond angles, dihedral angles, etc.), electron/charge distribution information, internal vibrational modes (for ideal gas properties), and energy of the molecule, valid for the chosen model chemistry. Because calculations are performed on individual molecules, they are primarily suited for ideal gas properties. Relative energies for the same model chemistry are more accurately obtained than absolute energies, so enthalpies and entropies of reaction are common industrial uses of CC predictions in addition to individual structural and ideal gas properties.

Empirical QSPR Correlations In quantitative structure property relationship (QSPR) methods, physical properties are correlated with molecular descriptors that characterize the molecular and electronic structure of the molecule. Large amounts of experimental data are used to statistically determine the most significant descriptors to be used in the correlation and their contributions. The resultant correlations are simple to apply if the descriptors are available. Descriptors must generally be generated by the user with computational chemistry software, although the DIPPR® 801 database now contains a table of molecular descriptors for most of the compounds in it. QSPR methods are often very accurate for specific families of compounds for which the correlation was developed, but extrapolation problems are even more of an issue than with GC methods.

Molecular Simulations Molecular simulations are useful for predicting properties of bulk fluids and solids. Molecular dynamics (MD) simulations solve Newton's equations of motion for a small number (on the order of 10^3) of molecules to obtain the time evolution of the system. MD methods can be used for equilibrium and transport properties. Monte Carlo (MC) simulations use a model for the potential energy between molecules to simulate configurations of the molecules in proportion to their probability of occurrence. Statistical averages of MC configurations are useful for equilibrium properties, particularly for saturated densities, vapor pressures, etc. Property estimations using molecular simulation techniques are not illustrated in the remainder of this section as commercial software implementations are not generally available at this time.

PHYSICAL CONSTANTS

Critical Properties The critical temperature T_c, pressure P_c, and volume V_c of a compound are important, widely used constants. They are important in determining the phase boundaries of a compound and (particularly T_c and P_c) are required input parameters for most thermal and volumetric property calculations of the equilibrium phases using CS or analytical equations of state. Most estimation methods employ weighted group, atom, or bond contributions.

The critical temperature of a compound is the temperature above which a liquid phase cannot be formed, no matter the pressure of the system. The critical pressure is the vapor pressure of the compound at the critical temperature. The critical volume is the volume occupied by a set amount of a compound (typically 1 mol) at its critical temperature and pressure.

The critical compressibility factor Z_c is determined from the experimental or predicted values of the critical properties by the definition

$$Z_c = \frac{P_c V_c}{R T_c} \tag{2-5}$$

Recommended Methods

Organic molecules: The Ambrose method is recommended for all three critical properties of hydrocarbons and *n*-alcohols. The Joback method is recommended for T_c and P_c of all other organic molecules. Fedors' method is recommended for V_c of these compounds, but the Joback method can also be used.

Inorganic molecules: The simple correlation $T_c = 1.64T_b$ is recommended if the normal boiling point is known. Critical pressure P_c is best obtained by extrapolating vapor pressure data to T_c, and V_c is best obtained from a correlation of liquid density extrapolated to T_c.

Other recent methods including the Wilson-Jasperson (Wilson, G. M., and L.V. Jasperson, *Critical Constants T_c, P_c, Estimation Based on Zero, First and Second Order Methods,* AIChE Spring Meeting, New Orleans, La., 1996) and Marrero-Pardillo [Marrero-Morejon, J., and E. Pardillo-Fontdevila, *AIChE J.*, **45** (1999): 615] methods have proved to be as good as or better for some classes of compounds than the methods presented here; however, their application is more difficult.

Method: Ambrose method.

Reference: Ambrose, D., Correlation and Estimation of Vapour-Liquid Critical Properties. I. Critical Temperatures of Organic Compounds, *Natl. Phys. Lab. Report Chem.* **92** (1978); Correlation and Estimation of Vapour-Liquid Critical Properties. II. Critical Pressures and Volumes of Organic Compounds, *Natl. Phys. Lab Report Chem.* **98** (1979).

Classification: Group contributions.

Expected uncertainty: ~6 K for T_c (about 1 percent), ~2 bar for P_c (about 5 percent), ~8 cm^3/mol for V_c (about 3 percent).

Applicability: Organic compounds.

Input data: T_b, M, group contributions Δ_T, Δ_P, and Δ_V from Table 2-336.

Description: A GC method with first-order contributions and corrections (delta Platt number) for branched alkanes. Variables T_c, P_c, and V_c are given by the following relations:

$$T_c = T_b\left[1 + \left(1.242 + \sum \Delta_T\right)^{-1}\right] \tag{2-6}$$

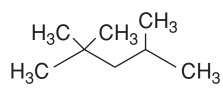
$$\frac{P_c}{\text{bar}} = \frac{M}{\text{kg/kmol}}\left(0.339 + \sum \Delta_P\right)^{-2} \tag{2-7}$$

$$\frac{V_c}{\text{cm}^3\text{/mol}} = 40 + \sum \Delta_V \tag{2-8}$$

Example Use the Ambrose method to estimate the critical constants of 2,2,4-trimethylpentane.

Required data: From the DIPPR® 801 database, $T_b = 372.39$ K and M = 114.229 kg/kmol.

Structure:



Group contributions from Table 2-336:

Group	n_i	Δ_T	Δ_P	Δ_V
Alkyl carbons	8	0.138	0.226	55.1
>CH— (correction)	1	–0.043	–0.006	–8
>C< (correction)	1	–0.120	–0.030	–17
Delta Platt no.	0	–0.023	–0.026	—

Calculations using Eqs. (2-6), (2-7), and (2-8):

$$\sum \Delta_T = (8)(0.138) + (1)(-0.043) + (1)(-0.120) = 0.941$$

$$T_c = T_b(1.4581) = (372.39 \text{ K})(1.4581) = 543.0 \text{ K}$$

$$\sum \Delta_P = (8)(0.226) + (1)(-0.006) + (1)(-0.030) = 1.772$$

$$\frac{P_c}{\text{bar}} = \frac{M}{\text{kg/kmol}}\left(0.339 + \sum \Delta_P\right)^{-2} = \frac{114.229}{(0.339 + 1.772)^2} = 25.63$$

$P_c = 25.63$ bar

TABLE 2-336 Ambrose Group[a] Contributions for Critical Constants

Group	Δ_T	Δ_P	Δ_V
Carbon atoms in alkyl groups	0.138	0.226	55.1
Corrections

Double bond (ring)	−0.030	—	
(other increments as in nonfluorinated compounds)			

[a]Ambrose, D., Correlation and Estimation of Vapour-Liquid Critical Properties. I. Critical Temperatures of Organic Compounds, *Natl. Phys. Lab Report Chem.* **92** (1978); Correlation and Estimation of Vapour-Liquid Critical Properties. II. Critical Pressures and Volumes of Organic Compounds, *Natl. Phys. Lab Report Chem.* **98** (1979).

[b]The delta Platt number is defined as the Platt number of the isomer minus the Platt number of the corresponding alkane. (For n-alkanes the Platt number is $n - 3$.) The Platt number is the total number of groups of four carbon atoms three bonds apart [Platt, J. R., *J. Chem. Phys.*, **15**(1947): 419; **56**(1952): 328]. This correction is used only for branched alkanes.

[c]Includes naphthenic alcohols and glycols but not aromatic alcohols such as xylenol.

[d]First determine the hydrocarbon homomorph, i.e., substitute —CH_3 for each —OH and calculate $\sum\Delta_T$ for this compound. Subtract 0.138 from $\sum\Delta_T$ for each —OH substituted. Next, add $0.87 - 0.11n + 0.003n^2$ where $n = [T_b/\text{K (alcohol)} - 314]/19.2$. Exceptions include methanol ($\sum\Delta_T = 0$), ethanol ($\sum\Delta_T = 0.939$), and any alcohol whose value of n exceeds 10.

[e]Determine the hydrocarbon homomorph as in footnote *d*. Calculate $\sum\Delta_p$ and subtract 0.226 for each —OH substituted. Add $0.100 - 0.013n$, where n is computed as in footnote *d*.

[f]When estimating the critical volumes of aromatic substances, use ring compound values, if available, and correct for double bonds.

$$\sum \Delta_V = (8)(55.1) + (1)(-8) + (1)(-17) = 415.8$$

$$V_c = (40 + 415.8)\ \text{cm}^3/\text{mol} = 455.8\ \text{cm}^3/\text{mol}$$

Results:

Property	DIPPR® recommended value	Ambrose estimation	% Difference
T_c/K	543.8	543.0	−0.15
P_c/bar	25.70	25.63	0.27
V_c/(cm^3/mol)	468.0	455.8	−2.6

Method: Joback method.
Reference: Joback, K. G., M.S. Thesis in Chemical Engineering, Massachusetts Institute of Technology, Cambridge, Mass., June 1984.
Classification: Group contributions.
Expected uncertainty: 7 K (~1 percent) for T_c; 2 bar (~5 percent) for P_c.
Applicability: Organic compounds.
Input data: T_b, group contributions Δ_T, Δ_P, Δ_V from Table 2-337, and the number of atoms in the molecule n_A.
Description: A GC method with first-order contributions. Variables T_c, P_c, and V_c are given by the following relations:

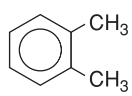
$$T_c = T_b\left[0.584 + 0.965\sum \Delta_T - \left(\sum \Delta_T\right)^2\right]^{-1} \tag{2-9}$$

$$\frac{P_c}{\text{bar}} = \left(0.113 + 0.0032 n_A - \sum \Delta_P\right)^{-2} \tag{2-10}$$

$$\frac{V_c}{\text{cm}^3/\text{mol}} = 17.5 + \sum \Delta_V \tag{2-11}$$

where Δ_T, Δ_P, Δ_V are group contributions from Table 2-337 and n_A is the number of atoms in the molecule.

Example Estimate the critical constants of *o*-xylene by using the Joback method.
Structure:



Required input data: From the DIPPR® 801 database, T_b = 417.58 K. From Table 2-337:

Group	n_i	Δ_T	Δ_P	Δ_V
=CH— (ring)	4	0.0082	0.0011	41
=C < (ring)	2	0.0143	0.0008	32
—CH_3	2	0.0141	−0.0012	65

From Eqs. (2-9), (2-10), and (2-11):

$$\sum \Delta_T = (4)(0.0082) + (2)(0.0143) + (2)(0.0141) = 0.0896$$

$$T_c = T_b[0.584 + 0.965\ (0.896) - (0.896)^2]^{-1}$$

$$T_c = T_b(1.5096) = (417.58\ \text{K})(1.5096) = 630.37\ \text{K}$$

$$n_A = 18 \qquad \sum \Delta_P = (4)(0.0011) + (2)(0.0008) + (2)(-0.0012) = 0.00360$$

$$\frac{P_c}{\text{bar}} = \left(0.113 + 0.0032 n_A - \sum \Delta_P\right)^{-2} = [0.113 + (0.0032)(18) - 0.0036]^{-2} = 35.86$$

$$P_c = 35.86\ \text{bar}$$

$$\sum \Delta_V = (4)(41) + (2)(32) + (2)(65) = 358$$

$$V_c = (17.5 + 358)\ \text{cm}^3/\text{mol} = 375.5\ \text{cm}^3/\text{mol}$$

*Fedors, R. F., *AIChE J.*, **25** (1979): 202.

$$\sum \Delta_T = (2)(0.0141) + (1)(0.0189) + (1)(0.0164) + (1)(0.0741) = 0.1376$$

$$T_c = T_b(1.4330) = (372.7\text{ K})(1.4330) = 534.1\text{ K}$$

$$\sum \Delta_P = (2)(-0.0012) + (1)(0.0020) + (1)(0.0112) = 0.0108 \qquad n_A = 15$$

$$\frac{P_c}{\text{bar}} = (0.1022 + 0.0032 n_A)^{-2} = \left[\frac{1}{0.1022 + (0.0032)(15)}\right]^2 = 44.33$$

$$P_c = 44.33\text{ bar}$$

$$\sum \Delta_V = (2)(65) + (1)(56) + (1)(41) + (1)(28) = 255$$

$$V_c = (17.5 + 255)\text{ cm}^3/\text{mol} = 272.5\text{ cm}^3/\text{mol}$$

Results:

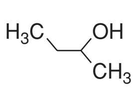
Property	DIPPR® 801 recommendation	Joback estimation	% Difference
T_c/K	536.2	534.1	−0.39
P_c/bar	42.02	44.33	5.50
V_c/(cm^3/mol)	269	272.5	1.30

Method: Fedor method.
Reference: Fedors, R. F., *AIChE J.*, **25** (1979): 202.
Classification: Atom/structure contributions.
Expected uncertainty: ~8 cm^3/mol (3 percent).
Applicability: Organic compounds.
Input data: Molecular structure, atom and structural increments, Δ_V in Table 2-238.
Description: An atom contribution method with structural increments for V_c, given by

$$\frac{V_c}{\text{cm}^3/\text{mol}} = 26.6 + \sum_{i=1}^{N} n_i \Delta_V \tag{2-12}$$

where Δ_V are structural contributions from Table 2-238.

Example Use Fedors' method to estimate the critical volume of *sec*-butanol.
Group contributions from Table 2-238:



Group	n_i	Δ_V
C	4	34.426
H	10	9.172
O (alcohol)	1	18.000

Calculation using Eq. (2-12):

$$\sum \Delta_V = (4)(34.426) + (10)(9.172) + (1)(18.000) = 247.4$$

$$V_c = (26.6 + 247.4)\text{ cm}^3/\text{mol} = 274.0\text{ cm}^3/\text{mol}$$

This value differs from the DIPPR® 801 recommended value of 269 cm^3/mol by 1.9 percent.

Mixtures Application of CS methods and analytical equations of state (EoS) to mixtures typically requires pseudocritical temperatures and pressures. These values are obtained from the pure-component critical properties by applying mixing rules specific to the method under consideration. While pseudocritical values should be used for mixture CS and EoS applications, the values are usually quite different from the mixture's true critical properties. A variety of methods are available for estimating true critical properties for mixtures (see PGL4), but only modest accuracy can be expected.

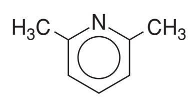
Normal Melting Point The *normal melting point* is defined as the temperature at which melting occurs at atmospheric pressure. Methods to estimate the melting point have not been particularly effective because the melting point depends strongly on solid crystal structure and that structure is not effectively correlated with standard GC or CS methods. If the triple point temperature is known, then the melting point is best estimated as being equal to the triple point temperature. However, rarely is the triple point temperature available if the melting point has not also been determined.

Recommended Method The method of Constantinou and Gani is recommended with caution.
Reference: Constantinou, L., and R. Gani, *AIChE J.*, **40** (1994): 1697.
Classification: Group contributions.
Expected uncertainty: 25 percent.
Applicability: Organic compounds.
Input data: First-order and second-order group contributions from molecular structure.
Description: A group contribution method given by

$$T_m = (102.425\text{ K}) \cdot \ln\left(\sum_i N_i t_{m1,i} + \sum_j N_j t_{m2,j}\right) \tag{2-13}$$

where N_i, N_j = number of first- and second-order groups, respectively
$t_{m1,i}$ = first-order group contributions from Table 2-339
$t_{m2,i}$ = second-order group contributions from Table 2-340

Example Estimate the melting point of 2,6-dimethylpyridine.
Structure and group contributions:



Group	N_i	$t_{m1,i}$	$t_{m2,i}$
$-CH_3$	2	0.4640	
$-C_5H_3(N)-$	1	12.6275	
Six-member ring	1		1.5656

Calculation using Eq. (2-13):

$$T_m = (102.425\text{ K}) \ln[(2)(0.4640) + 12.6275 + 1.5656] = 278\text{ K}$$

The predicted value is 4 percent higher than the recommended experimental value of 267 K in the DIPPR® 801 database.

Normal Boiling Point The normal boiling temperature T_b is the temperature at which the vapor pressure of the liquid equals 101.325 kPa (1.0 atm). In some (usually older) literature sources, T_b values were reported at ambient pressures rather than at 101.325 kPa. If two or more such values are available, they can be be used to obtain T_b by using Eq. (2-2) to linearly interpolate ln P^* vs. $1/T$ values.

If there are sufficient vapor pressure data available, then T_b may be found from a regression of the data using an appropriate vapor pressure equation [e.g., Eqs. (2-21)–(2-26)]. If one or a few vapor pressure data at low pressure are available, a common occurrence, then the method of Pailhes can be used to estimate T_b. The most accurate method for prediction of normal boiling temperatures without experimental data is the Nannoolal method.

TABLE 2-339 First-Order Groups and Their Contributions for Melting Point*

*Constantinou, L., and R. Gani, *AIChE J.*, **40** (1994): 1697.

Recommended Method Pailhes method.
Classification: Group contributions.
Expected uncertainty: 3 K (~1 to 2 percent).
Applicability: Organic compounds.
Reference: Pailhes, F., *Fluid Phase Equilib.*, **41** (1988): 97.
Input data: Molecular structure and one measured vapor pressure value P^*_{meas}, (often at a low pressure). The method requires estimation of T_c and P_c using a group contribution method. The original Pailhes method used the Lyderson method [Lydersen, A. L., *AIChE J.*, **21** (1975): 510], but the Joback method is illustrated here for consistency with the previous examples on critical constant estimation.

Description: A simple group contribution method given by

$$T_b = T_{meas} \frac{\log(P_c/\text{bar}) + (1 - T_{br})x_P}{\log(P_c/\text{bar})} - 3x_P - 1.49x_P^2 \qquad (2\text{-}14)$$

where T_b = estimate of normal boiling point
P_c = critical pressure estimated from group contributions
T_{br} = reduced normal boiling point estimated from Eq. (2-9)
$x_P = \log(1\ \text{atm}/P^*_{meas})$
T_{meas} = temperature at which experimental vapor pressure is known

TABLE 2-340 Second-Order Groups and Their Contributions for Melting Point*

Group	$t_{m21,i}$	Group	$t_{m21,i}$

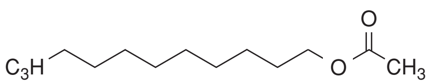
ACCHO	−0.6697	ACl	−1.5511

*Constantinou, L., and R. Gani, *AIChE J.*, **40** (1994): 1697.

Example The vapor pressure of n-decylacetate at 348.65 K is 106.66 Pa. Estimate the normal boiling point of this compound.

Structure and group contributions from Table 2-337:



Group	n_i	Δ_T	Δ_P
—CH3	2	0.0141	–0.0012
$>CH_2$	9	0.0189	0
—COO— (ester)	1	0.0481	0.0005

Group contribution calculations using Eqs. (2-9) and (2-10):

$$\sum \Delta_T = (2)(0.0141) + (9)(0.0189) + (1)(0.0481) = 0.2464$$

$$T_{br} = 0.584 + 0.965(0.2464) - (0.2464)^2 = 0.76106$$

$$\sum \Delta_P = (2)(-0.0012) + (1)(0.0005) = -0.0019$$

$$n_A = 38 \qquad P_c = (0.113 + 0.0032 n_A + 0.0019)^{-2}\ \text{bar} = 17.88\ \text{bar} = 17.65\ \text{atm}$$

Calculation of auxiliary quantities:

$$x_P = \log \frac{1\ \text{atm}}{P^{\circ}_{\text{meas}}} = \log \frac{101325\ \text{Pa}}{106.66\ \text{Pa}} = 2.9777$$

Calculation of normal boiling point using Eq. (2-14):

$$\frac{T_b}{\text{K}} = 348.65 \frac{\log 17.88 + (1 - 0.76016)(2.9777)}{\log 17.88} - 3(2.9777) - 1.49(2.9777)^2$$

$$T_b = 525.3\ \text{K}$$

The estimated value is 1.6 percent higher than the DIPPR® 801 recommended value of 517.15 K.

Recommended Method Nannoolal method.

Reference: Nannoolal, Y., et al., *Fluid Phase Equilib.*, **226** (2004): 45.

Classification: Group contributions.

Expected uncertainty: 7 K (on the order of 2 percent).

Applicability: Organic compounds for which group values are available.

Input data: GC values C_i in Table 2-341; intramolecular group-group interactions C_{ij} in Table 2-342.

Description: A GC method that includes second-order corrections for steric effects and intramolecular interactions. Variable T_b is found from

$$\frac{T_b}{K} = \frac{\sum_{i=1}^{N} n_i \cdot C_i}{n^{0.6583} + 1.6868} + 84.3395 \tag{2-15}$$

where n = number of nonhydrogen atoms
n_i = number of occurrences of group i
N = number of groups
C_i = group contribution from Table 2-341 or Eq. (2-16)

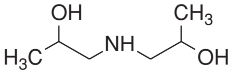
Corrections for intramolecular group-group interactions $C_{i,\text{int}}$ are made by dividing the sum of all unique group pairs within the molecule by n. This can be written as

$$C_{i,\text{int}} = \frac{1}{n} \sum_{i=1}^{N} \sum_{j>i}^{N} C_{ij} \tag{2-16}$$

or thought of as the sum of terms in the upper half (above and to the right of the diagonal) of the square matrix formed by listing each group in the molecule along the row and column. The values for the interactions are shown in this format in Table 2-342.

Example Estimate the normal boiling point of di-isopropanolamine by using the Nannoolal method.

Structure:



Group contributions and values:

Group	n_i	C_i	Group total
—CH3	2	177.3066	354.6132
>C(c)<(e)	4	266.8769	1067.508
—OH sec	2	390.2446	780.4892
—NH—	1	223.0992	223.0992
Corrections			
—OH::—OH	1/9	291.7985	32.42206
—OH::—NH—	2/9	286.9698	63.77107
		Total	2521.902

Note that there are three interacting groups (—OH, —OH, —NH—) in the molecule which gives two —OH::—NH— interactions and one —OH::—OH interaction which are then divided by n (= 9) as in Eq. (2-16) to give the frequency.

Calculation using Eq. (2-15):

$$\frac{T_b}{K} = \frac{2521.902}{9^{0.6583} + 1.6868} + 84.3395 = 509.3 \qquad T_b = 509.3\ \text{K}$$

The calculated value differs by –2.4 percent from the DIPPR® 801 recommended value of 521.9 K.

Characterizing and Correlating Constants

Acentric Factor The acentric factor of a compound ω is defined in terms of the reduced vapor pressure evaluated at a reduced temperature of 0.7 as

$$\omega = -\log P_r^{\circ}\Big|_{T_r = 0.7} - 1.0000 \tag{2-17}$$

It is primarily used as a third parameter (beyond T_c and P_c) in CS predictions as a measure of deviations from nonspherical molecular shape, hence the name, suggesting molecular interactions that are not between centers of molecules. However, as defined in Eq. (2-17), ω also contains polarity information, and ω increases slightly with increasing polarity for molecules of similar size and shape. The value of ω is close to zero for small, spherically shaped, nonpolar molecules (argon, methane, etc.). It increases in value with larger deviations of molecular shape from spherical (longer chain lengths, less chain branching, etc.) and with increasing molecular polarity. When possible, ω should be obtained from experimental vapor pressure correlations by using Eq. (2-17), but an accurate estimation of ω can be made by using the critical constants and a single vapor pressure point by application of CS vapor pressure equations.

Recommended Method Ambrose-Walton modification of Lee-Kesler vapor pressure equations.

References: Ambrose, D., and J. Walton, *Pure & Appl. Chem.*, **61** (1989): 1395; Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

Classification: Corresponding states.

Expected uncertainty: Generally within 5 percent.

Applicability: Most organic compounds.

Input data: T_c, P_c, and a single vapor pressure point (e.g., the normal boiling point).

Description: See Eq. (2-25) for the equations used in this method. The vapor pressure equation is inverted to obtain the acentric factor from a single experimental vapor pressure point.

Example Calculate the acentric factor of chlorobenzene with a known value for T_b.

Input information: From the DIPPR® 801 database, T_b = 404.87 K, T_c = 632.35 K, and P_c = 45.1911 bar.

Calculation of auxiliary quantities:

$$T_{br} = \frac{T_b}{T_c} = \frac{404.87}{632.35} = 0.64 \qquad \tau = 1 - 0.64 = 0.36$$

$$f^{(0)} = \frac{(-5.97616)(0.36) + (1.29874)(0.36)^{1.5} - (0.60394)(0.36)^{2.5} - (1.06841)(0.36)^5}{0.64}$$

$$= -3.0034$$

$$f^{(1)} = \frac{(-5.03365)(0.36) + (1.11505)(0.36)^{1.5} - (5.41217)(0.36)^{2.5} - (7.46628)(0.36)^5}{0.64}$$

$$= -3.1788$$

*Nannoolal, Y., et al., *Fluid Phase Equilib*. **226** (2004): 45.

$$f^{(2)} = \frac{(-0.64771)(0.36) + (2.41539)(0.36)^{1.5} - (4.26979)(0.36)^{2.5} + (3.25259)(0.36)^{5}}{0.64}$$

$$= -0.037$$

Calculation using Eq. (2-25) at the normal boiling point:

$$\ln \frac{1.01325}{45.1911} = -3.798 = f^{(0)} + \omega f^{(1)} + \omega f^{(2)} = 3.0034 + 3.1788\omega + 0.037\omega^2$$

$$\omega = 0.249$$

The value obtained from the Ambrose-Walton-Lee-Kesler method compares favorably with the value of 0.2499 recommended in the DIPPR® 801 database (obtained from the vapor pressure correlation).

Radius of Gyration The radius of gyration R_g is a measure of the mass distribution about the center of mass of a molecule. Radius R_g increases with molecular size. It is useful in CS applications to separate molecular size and shape effects from polar effects. It is defined in terms of the principal moments of inertia of a molecule (*A, B,* and *C*) as

$$R_g = \sqrt{\frac{(AB)^{1/2} N_A}{M}} \tag{2-18}$$

for planar molecules and as

$$R_g = \sqrt{\frac{2\pi (ABC)^{1/3} N_A}{M}} \tag{2-19}$$

*Nannoolal, Y., et al., *Fluid Phase Equilib.*, **226** (2004): 45.

for nonplanar molecules. Radii of gyration can be calculated from these defining equations and principal moments of inertia obtained from spectral data or from computational chemistry software.

Recommended Method Principal moments of inertia.

Classification: Computational chemistry.

Expected uncertainty: Less than 5 percent.

Applicability: All molecules.

Input data: M and molecular structure.

Description: Computational chemistry software is used to optimize the geometry of the molecule and obtain the principal moments of inertia to be used in Eqs. (2-18) and (2-19).

Example Calculate the radius of gyration for hydrazine.

Input information: From the DIPPR® 801 database, $M = 32.0452$ kg/kmol. The structure of hydrazine is

$$H_2N—NH_2$$

Calculation of the principal moments of inertia: Optimizing hydrazine with HF/6-31G model chemistry gives the following principal moments of inertia:

$$A = 12.24050 \text{ amu·Bohr}^2 \qquad B = 72.41081 \text{ amu·Bohr}^2$$
$$C = 79.16893 \text{ amu·Bohr}^2$$

Conversion from atomic units to SI gives

$$A = (12.24050 \text{ amu·Bohr}^2)\left(\frac{5.29177\times10^{-11}\text{ m}}{\text{Bohr}}\right)^2\left(\frac{1.66054\times10^{-27}\text{ kg}}{\text{amu}}\right)$$
$$= 5.692\times10^{-47}\text{ kg·m}^2$$

$$B = (72.41081 \text{ amu·Bohr}^2)\left(\frac{4.65010^{-48}\text{ kg}\cdot\text{m}^2}{\text{amu}\cdot\text{Bohr}^2}\right) = 3.367\times10^{-46}\text{ kg·m}^2$$

$$C = (79.16893 \text{ amu·Bohr}^2)\left(\frac{4.65010^{-48}\text{ kg}\cdot\text{m}^2}{\text{amu}\cdot\text{Bohr}^2}\right) = 3.681\times10^{-46}\text{ kg·m}^2$$

Calculation using Eq. (2-19):

$$(ABC)^{1/3} = [(5.692\times10^{-47})(3.367\times10^{-46})(3.681\times10^{-46})]^{1/3}\text{ kg·m}^2$$
$$= 1.918\times10^{-46}\text{ kg·m}^2$$

$$R_g = \sqrt{\frac{2\pi(1.918\times10^{-46}\ \text{kg}\cdot\text{m}^2)(6.022\cdot10^{26}\ \text{kmol}^{-1})}{32.0452\ \text{kg/kmol}}} = 1.505\times10^{-10}\ \text{m}$$

This is 3.8 percent below the DIPPR® 801 database value of 1.564×10^{-10} m which was obtained from spectral principal moments of inertia.

Dipole Moment The dipole moment of a molecule is the first moment of the electric charge density expansion. All normal paraffins have a value of zero. Charge separation within the molecule due to electronegativity differences between bonded atoms increases the dipole moment. Computational chemistry software uses the electron density distribution of the optimized molecule to calculate dipole moments.

Recommended Method Electron density distribution.
Classification: Computational chemistry.
Expected uncertainty: Uncertainty varies depending upon the model chemistry chosen, but it can be as large as 60 percent.
Applicability: All molecules.
Input data: Molecular structure.

Example Calculate the dipole moment for methanol.
Draw structure and optimize molecule using computational chemistry software: The dipole moment obtained from a geometry optimized with the HF/6-31G model chemistry for methanol is 2.288 D. This value is 35 percent larger than the experimental gas-phase value of 1.700 D in the DIPPR® 801 database.

VAPOR PRESSURE

Liquids Vapor pressure is the most important of the basic thermodynamic properties of fluids. It is the pressure of equilibrium, coexisting liquid and vapor phases at a specified temperature. The vapor pressure curve is a monotonic function of temperature from its minimum value (the triple point pressure) at the triple point temperature T_t to its maximum value (the critical pressure) at T_c.

Liquid vapor pressure data over a limited temperature range can be correlated with the Antoine [Antoine, C, *C.R.*, **107** (1888): 681, 836] equation

$$\ln \frac{P^*}{\text{Pa}} = A - \frac{B}{\text{T/K} + C} \tag{2-20}$$

Data from the triple point to the critical point can be correlated with either a modified form of the Wagner equation [Wagner, W., *"A New Correlation Method for Thermodynamic Data Applied to the Vapor-Pressure Curve of Argon, Nitrogen, and Water,"* J.T.R. Watson (trans. and ed.), IUPAC Thermodynamic Tables Project Centre, London, 1977; Ambrose, D., *J. Chem. Thermodyn.*, **18** (1986): 45; Ambrose, D., and N. B. Ghiassee, *J. Chem. Thermodyn.*, **19** (1987): 903, 911]

$$\ln P_r^* = \frac{a\tau + b\tau^{1.5} + c\tau^{2.5} + d\tau^5}{1-\tau} \qquad \text{where } \tau \equiv 1 - T_r \tag{2-21}$$

or the Riedel [Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 679] equation

$$\ln \frac{P^*}{\text{Pa}} = A + \frac{B}{T/\text{K}} + C \ln \frac{T}{\text{K}} + D\left(\frac{T}{\text{K}}\right)^E \tag{2-22}$$

Generally, E in Eq. (2-22) is assigned a value of 6, but values of 2 or 1 have also been used, particularly when correlating low-temperature data. While the Wagner equation can be used to correlate most fluids over the whole liquid range, a fifth term is often required for alcohols [Poling, B. E., *Fluid Phase Equil.,* **116** (1996): 102]:

$$\ln P_r^* = \frac{a\tau + b\tau^{1.5} + c\tau^{2.5} + d\tau^5 + e\tau^6}{1-\tau} \qquad \text{(for alcohols)} \tag{2-23}$$

Correlation of experimental data within a few tenths of a percent over the entire fluid range can usually be obtained with either the Wagner or Riedel equations.

Two prediction methods are recommended for liquid vapor pressure. The first method is based on the Riedel equation; the second is a CS method. Both methods require T_c and P_c as input, but these can be estimated by the methods shown earlier if experimental values are unavailable.

Recommended Method 1 Riedel method.
Reference: Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 679
Classification: Empirical extension of theory and corresponding states.
Expected uncertainty: Varies strongly depending upon relative T, but 1 percent or less above T_b is typical with uncertainties of 5 to 30 percent near the triple point.
Applicability: Most organic compounds.
Input data: T_b, T_c, P_c.
Description: Equation (2-22) in reduced form

$$\ln P_r = A + \frac{B}{T_r} + C \ln T_r + DT_r^6 \tag{2-24}$$

Constants for this equation are determined from the following set of relationships:

$$\psi = -35 + \frac{36}{T_{br}} + 42 \ln T_{br} - T_{br}^6 \qquad \alpha_c = \frac{3.758K\psi + \ln(P_c/1.01325\ \text{bar})}{K\psi - \ln T_{br}}$$

$$h = T_{br}\frac{\ln(P_c/1.01325\ \text{bar})}{1 - T_{br}} \qquad D = K(\alpha_c - 3.758)$$

$$C = \alpha_c - 42D \qquad B = -36D \qquad A = 35D$$

Values of the constant K [Vetere, A., *Ind. Eng. Chem Res.*, **30** (1991): 2487]:

Class	Value
Acids	$K = -0.120 + 0.025h$
Alcohols	$K = 0.373 - 0.030h$
All other organic compounds	$K = 0.0838$

Example Estimate the vapor pressure of chlorobenzene at 50 K intervals from 300 to 600 K.
Input information: From the DIPPR® 801 database, T_b = 404.87 K, T_c = 632.35 K, and P_c = 45.1911 bar.
Auxiliary Quantities:

$$K = 0.0838 \qquad T_{br} = 404.87/632.35 = 0.640$$

$$\psi = -35 + \frac{36}{0.640} + 42 \ln 0.640 - (0.640)^6 = 2.431$$

$$\alpha_c = \frac{(3.758)(0.0838)(2.431) + \ln(45.191/1.01325)}{(0.0838)(2.431) - \ln(0.640)} = 7.0248$$

$$D = (0.0838)(7.0248 - 3.758) = 0.2738 \qquad C = 7.0248 - (42)(0.2738) = -4.4729$$

$$B = -(36)(0.2738) = -9.8552 \qquad A = -(35)(0.2738) = 9.5814$$

Calculation using Eq. (2-24) at each T (detailed calculation shown for T = 500 K):

$$T_r = 500/632.35 = 0.7907$$

$$\ln P_r = 9.5814 - \frac{9.8552}{0.7907} - 4.4729 \ln 0.7907 + (0.2738)(0.7907)^6 = -1.7651$$

$$P_r = \exp(-1.7651) = 0.1712 \qquad P = P_rP_c = (0.1712)(45.1911\ \text{bar}) = 7.74\ \text{bar}$$

T/K	T_r	ln P_r	P/bar	P_{DIPPR}/bar	% Error
300	0.4744	−7.8532	0.0176	0.0175	0.3
350	0.5535	−5.5704	0.172	0.172	0.1
400	0.6326	−3.9323	0.886	0.880	0.6
450	0.7116	−2.7101	3.01	2.98	0.9
500	0.7907	−1.7651	7.74	7.67	0.9
550	0.8698	−1.0067	16.51	16.39	0.8
600	0.9488	−0.3705	31.20	31.11	0.3

Recommended Method 2 Ambrose-Walton method.
References: Ambrose, D., and J. Walton, *Pure & Appl. Chem.,* **61** (1989): 1395; Lee, B. I., and M. G. Kesler, *AIChE J.,* **21** (1975): 510.

Classification: Corresponding states.

Expected uncertainty: Varies strongly with relative T, but less than 1 percent is typical above T_b if the acentric factor is known.

Applicability: Most organic compounds.

Input data: T_b, T_c, P_c, and ω.

Description: The acentric factor is used to linearly interpolate within the simple-fluid and deviation terms for the ln P^* values of the reference fluids, which themselves have been correlated with the Wagner vapor pressure equation.

$$\ln P_r^* = f^{(0)} + \omega f^{(1)} + \omega^2 f^{(2)}$$

$$f^{(0)} = \frac{-5.97616\tau + 1.29874\tau^{1.5} - 0.60394\tau^{2.5} - 1.06841\tau^5}{1-\tau}$$

$$f^{(1)} = \frac{-5.03365\tau + 1.11505\tau^{1.5} - 5.41217\tau^{2.5} - 7.46628\tau^5}{1-\tau} \tag{2-25}$$

$$f^{(2)} = \frac{-0.64771\tau + 2.41539\tau^{1.5} - 4.26979\tau^{2.5} + 3.25259\tau^5}{1-\tau}$$

where $\tau = 1 - T_r$.

Example Repeat the calculation of the liquid vapor pressure of chlorobenzene at 50 K intervals from 300 to 600 K.

Input information: From the DIPPR® 801 database, T_c = 632.35 K, P_c = 45.1911 bar, and ω = 0.249857.

Auxiliary quantities:

$$T_r = 500/632.35 = 0.7907 \qquad \tau = 1 - 0.7907 = 0.2093$$

Simple-fluid and deviation vapor pressure terms at each T (shown for T = 500 K):

$$f^{(0)} = \frac{(-5.97616)(0.2093) + (1.29874)(0.2093)^{1.5} - (0.60394)(0.2093)^{2.5} - (1.06841)(0.2093)^5}{0.7907} = -1.4405$$

$$f^{(1)} = \frac{(-5.03365)(0.2093) + (1.11505)(0.2093)^{1.5} - (5.41217)(0.2093)^{2.5} - (7.46628)(0.2093)^5}{0.7907} = -1.3383$$

$$f^{(2)} = \frac{(-0.64771)(0.2093) + (2.41539)(0.2093)^{1.5} - (4.26979)(0.2093)^{2.5} + (3.25259)(0.2093)^5}{0.7907} = 0.0145$$

Calculation using Eq. (2-25):

$\ln P_r^* = -1.4405 + (0.249857)(-1.3383) + (0.249857)^2(0.0145) = -1.774$

$P^* = (45.1911 \text{ bar})[\exp(-1.774)] = 7.667$ bar

T	τ	$f^{(0)}$	$f^{(1)}$	$f^{(2)}$	$\ln P_r^*$	P^*/bar	P^*_{DIPPR}/bar	% Error

Solids Below the triple point, the pressure at which the solid and vapor phases of a pure component are in equilibrium at any given temperature is the vapor pressure of the solid. It is a monotonic function of temperature with a maximum at the triple point. Solid vapor pressures can be correlated with the same equations used for liquids. Estimation of solid vapor pressure can be made from the integrated form of the Clausius-Clapeyron equation

$$\ln \frac{P^*}{P_t^*} = \frac{\Delta H_{\text{sub}}}{RT_t}\left(1 - \frac{T_t}{T}\right) \tag{2-26}$$

where T_t = triple point temperature
P_t^* = triple point pressure
ΔH_{sub} = enthalpy of sublimation

The liquid and solid vapor pressures are identical at the triple point. A good vapor pressure correlation that is valid at the triple point may be used to obtain the triple point pressure. Estimating solid vapor pressures by using Eq. (2-26) generally requires an estimation of ΔH_{sub}, and so the illustrative example is combined with the example on enthalpy of sublimation in the section on latent enthalpy.

THERMAL PROPERTIES

Enthalpy of Formation The standard enthalpy (heat) of formation is the enthalpy change upon formation of 1 mol of the compound in its standard state from its constituent elements in their standard states. Two different standard enthlapies of formation are commonly defined based on the chosen standard state. The standard state enthalpy of formation ΔH_f^s uses the naturally occurring phase at 298.15 K and 1 bar as the standard state; the ideal gas standard enthalpy (heat) of formation ΔH_f^o uses the compound in the ideal gas state at 298.15 K and 1 bar as the standard state. In both cases, the standard state for the elements is their naturally occurring state of aggregation at 298.15 K and 1 atm. Sources for data include DIPPR®, TRC, SWS, JANAF, and Daubert, T. E., and R. P. Danner, *Technical Data Book—Petroleum Refining*, 5th ed., American Petroleum Institute, Washington, extant 1994. The Domalski-Hearing method is the most accurate general method for estimating either ΔH_f^s or ΔH_f^o if the appropriate GC values are available, but a CC method is also as accurate for estimating ΔH_f^o if an isodesmic reaction can be formulated and used. The Domalski-Hearing method also applies to entropies, and the entropy predictive equations are listed in this section for convenience because they are equivalent in form to the enthalpy equations. However, discussion and illustration of the estimation methods for entropy are delayed to the next subsection.

Recommended Method Domalski-Hearing method.

Reference: Domalski, E. S., and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805.

Classification: Group contributions.

Expected uncertainty: 3 percent.

Applicability: Organic compounds for which group contributions have been regressed.

Input data: Molecular structure.

Description: GC values from Table 2-343 are directly additive for both enthalpy of formation and absolute third-law entropies:

$$\frac{\Delta H_f^\circ}{\text{kJ/mol}} = \sum_{i=1}^{N} n_i (\Delta H_f^\circ)_i \qquad \frac{S^\circ}{\text{J}\cdot\text{mol}^{-1}\text{K}^{-1}} = \sum_{i=1}^{N} n_i (S^\circ)_i \tag{2-27}$$

where $(\Delta H_f^o)_i$ = enthalpy of formation GC value from Table 2-343 and $(S^o)_i$ = entropy GC value from Table 2-343.

Group values in Table 2-343 are defined by the central, nonhydrogen group and the atoms bonded to that group. Thus, C—(2H)(2C) represents a C atom to which 2 H and 2 C atoms are bonded. For example, propane (CH_3—CH_2—CH_3) is composed of three groups: two C—(3H)(C) and one C—(2H)(2C).

Example Estimate the standard and ideal gas enthalpies of formation of *o*-toluidine.

Input information: The melting point (256.8 K) and boiling point (473.49 K) given for *o*-toluidine in the DIPPR® 801 database bracket 298.15 K, and so the standard state phase at 298.15 K and 1 bar must be liquid.

TABLE 2-343 Domalski-Hearing* Group Contribution Values for Standard State Thermal Properties (*Concluded*)

This table is a partial listing of GC values available from the original Domalski-Hearing tables. Table-specific nomenclature: Cd = carbon with double bond; Ct = carbon with triple bond; Cb = carbon in benzene ring; Ca = allenic carbon; corr = correction term; Cbf = fused benzene ring; N_A = azo nitrogen; N_I = imino nitrogen.

*Domalski, E. S, and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805

Group contributions:

Group	n_i	ΔH_f° gas	ΔH_f° liq.	S° gas	S^s liq.
Cb—(H)(2Cb)	4	13.81	8.16	48.31	28.87
Cb—(C)(2Cb)	1	23.64	19.16	−35.61	−19.50
Cb—(N)(2Cb)	1	−1.30	1.50	−43.53	−24.43
C—(3H)(C)	1	−42.26	−47.61	127.32	83.30
N—(2H)(Cb)	1	19.25	−11.00	126.90	71.71
Total		54.57	−5.31	368.32	226.56

Calculation from Eq. (2-27):

$$\frac{\Delta H_f^o}{\text{kJ/mol}} = 54.57 \qquad \frac{\Delta H_f^s}{\text{kJ/mol}} = -5.31$$

$$\frac{S^o}{\text{J/(mol·K)}} = 368.32 \qquad \frac{S^o}{\text{J/(mol·K)}} = 226.56$$

The recommended DIPPR® 801 standard enthalpies of formation are ΔH_f^o = 53.20 kJ/mol and $\Delta H_f^s = -4.72$ kJ/mol; the estimated values are higher than the recommended values by 2.6 and 12.5 percent, respectively. The recommended DIPPR® 801 standard entropies are S^o = 355.8 J/(mol·K) and S^s = 231.2 J/(mol·K). The estimated values differ from these by 3.5 and − 2.0 percent, respectively.

Recommended Method Isodesmic reaction.

Reference: Foresman, J. B., and A. Frisch, *Exploring Chemistry with Electronic Structure Methods*, 2d ed., Gaussian Inc., Pittsburgh, Pa., 1996.

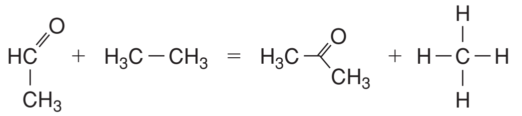
Classification: Computational chemistry.

Expected uncertainty: 5 to 10 percent depending upon the level of theory and basis set size used.

Applicability: Compounds for which an isodesmic reaction can be formulated.

Input data: Experimental ΔH_f^o values for all *other* participants in the isodesmic reaction.

Description: While *ab initio* calculations of absolute enthalpies are not currently as accurate as GC methods, *relative* enthalpies of molecules calculated with the same level of theory and basis set can be very accurate, as in the case of isodesmic reactions. An isodesmic reaction is one in which the number and type of bonds are preserved during the reaction. For example, the reaction of acetaldehyde with ethane to form acetone and methane



is isodesmic with 12 single bonds and 1 double bond in both reactants and products. To use this method, one devises an isodesmic reaction involving the compound for which ΔH_f^o is to be determined and other compounds for which experimental ΔH_f^o values are available. *Ab initio* calculations are performed on all the participating compounds, all at the same level of theory and basis set size, to obtain the enthalpy for each at 298.15 K. The enthalpy of reaction is then calculated from

$$\Delta H_{rxn} = \sum \nu_i H_i \tag{2-28}$$

where ν_i = stoichiometric coefficient of i (+ for products, − for reactants). The enthalpy of reaction is also related to ΔH_f^o by

$$\Delta H_{\text{rxn}} = \sum \nu_i (\Delta H_f^o)_i \tag{2-29}$$

With experimental values available for all ΔH_f^o except the desired compound, its value can be back-calculated from Eq. (2-29).

Example Estimate the standard ideal gas enthalpy of formation of acetaldehyde.

Input information: The isodesmic reaction shown above will be used. The recommended ΔH_f^o values from DIPPR® 801 for the other three compounds are

Acetone	Methane	Ethane
−215.70 kJ/mol	−74.52 kJ/mol	−83.82 kJ/mol

Ab initio calculations of enthalpy: With structures optimized using HF/6-31G(d) model chemistry and energies calculated with B3LYP/6-311 + G(3df,2p), the following enthalpies are obtained (including the zero point energy):

Acetone	Methane	Ethane	Acetaldehyde
-5.071×10^5 kJ/mol	-1.063×10^5 kJ/mol	-2.095×10^5 kJ/mol	-4.039×10^5 kJ/mol

Calculation using Eq. (2-28):

$$\Delta H_{\text{rxn}} = (-1.063 - 5.071 + 2.095 + 4.039) \times 10^5 \text{ kJ/mol} = -41.67 \text{ kJ/mol}$$

Calculation using Eq. (2-29):

$$\Delta H^o_{f,\text{acetaldehyde}} = \Delta H^o_{f,\text{acetone}} + \Delta H^o_{f,\text{methane}} - \Delta H^o_{f,\text{ethane}} - \Delta H_{rxn}$$

$$\Delta H^o_{f,\text{acetaldehyde}} = (-215.70 - 74.52 + 83.82 + 41.67)\frac{\text{kJ}}{\text{mol}} = -164.73\frac{\text{kJ}}{\text{mol}}$$

The estimated value is 1.0 percent above the DIPPR® 801 recommended value of −166.40 kJ/mol.

Entropy Absolute or third-law entropies (relative to a perfectly ordered crystal at 0 K) of a compound in its standard state S^s or of an ideal gas S^o at 298.15 K and 1 bar can be found in various literature sources (DIPPR, JANAF, TRC, SWS, and Daubert, T. E., and R. P. Danner, *Technical Data Book-Petroleum Refining*, 5th ed., American Petroleum Institute, Washington, extant 1994). Very good estimates for S^s or S^o can be obtained by using the Domalski-Hearing method. Excellent S^o values can also be obtained from statistical mechanics by using experimental vibrational frequencies or values of the frequencies generated from computational chemistry.

The standard state ΔS_f^s and standard ideal gas ΔS_f^o entropies of formation at 298.15 K and 1 bar are related to the standard entropies by

$$\Delta S_f^s = S^s_{\text{compound}} - \sum_{i=1}^{n_A} \nu_i S^s_{\text{element},i} \qquad \Delta S_f^o = S^o_{\text{compound}} - \sum_{i=1}^{n_A} \nu_i S^s_{\text{element},i} \tag{2-30}$$

where $S^s_{\text{element},i}$ is the absolute entropy of element i in its standard state at 298.15 K and 1 bar.

Recommended Method Domalski-Hearing method.

Reference: Domalski, E. S., and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805.

Classification: Group contributions.

Expected uncertainty: 3 percent.

Applicability: Organic compounds for which group contributions have been regressed.

Input data: Molecular structure.

Description: See description given under Enthalpy of Formation above.

Example Estimate the standard and ideal gas entropies of formation of *o*-toluidine.

Standard state entropies: Estimation of S^s and S^o using the Domalski-Hearing method was illustrated above in the Enthalpy of Formation section. The standard entropies of formation can be obtained from the values determined in that example.

Formula: C_7H_9N. The standard state entropies of the elements from the DIPPR® 801 database are as follows:

Compound:	N_2	H_2	C, graphite
ν_i:	1/2	9/2	7
S_i^s/[J(kmol·K)]:	1.9151×10^5	1.3057×10^5	5740

Entropies of formation can be calculated from these values by using Eq. (2-30):

$$\Delta S_f^s = \left[0.22656 - \left(\frac{1}{2}\right)(1.9151) - \left(\frac{9}{2}\right)(1.3057) - (7)(0.0574)\right]\frac{10^5\text{ J}}{\text{kmol}\cdot\text{K}}$$

$$= -7.008 \cdot 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

$$\Delta S_f^o = \left[0.36832 - \left(\frac{1}{2}\right)(1.9151) - \left(\frac{9}{2}\right)(1.3057) - (7)(0.0574)\right]\frac{10^5\text{ J}}{\text{kmol}\cdot\text{K}}$$

$$= -6.867 \cdot 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

Recommended Method Statistical mechanics.

Classification: Theory and computational chemistry.

Expected uncertainty: 0.2 percent if vibrational frequencies (or their characteristic temperatures) are experimentally available; uncertainty depends upon model chemistry if frequencies are determined from computational chemistry, but generally within about 5 percent.

Applicability: Ideal gases.

Input data: M; σ (external symmetry number); characteristic rotational temperature(s) (Θ_A for linear molecules; Θ_A, Θ_B, and Θ_C for nonlinear molecules); and $3n_A - 6 + \delta$ characteristic vibrational temperatures Θ_j.

Description: For harmonic frequencies, the rigorous temperature dependence of S^o is given by

$$\frac{S^o}{R} = \frac{3}{2}\ln\left(6175\frac{M}{\text{kg/kmol}}\right) + \frac{S_r}{R} + \sum_{j=1}^{3n_A-6+\delta}\left[\left(\frac{\Theta_j}{T}\right)(e^{\Theta/T} - 1)^{-1} - \ln(1 - e^{-\Theta/T})\right] \tag{2-31}$$

$$\text{where } \delta = \begin{cases} 0 & \text{nonlinear} \\ 1 & \text{linear} \end{cases}$$

$$\frac{S_r}{R} = \begin{cases} \ln\left[\frac{1}{\sigma}\left(\frac{\pi T^3 e^3}{\Theta_A \Theta_B \Theta_C}\right)^{1/2}\right] & \text{nonlinear} \\ \ln\left[\left(\frac{Te}{\sigma\Theta_A}\right)^{1/2}\right] & \text{linear} \end{cases}$$

$T = 298.15$ K

Example Calculate S^o for ammonia.
Structure: NH_3.
Input data: M = 17 kg/kmol. McQuarrie [McQuarrie, D. A., *Statistical Mechanics*, Harper & Row, New York, 1976] gives the following $3m - 6 + \delta = 12 - 6 + 0 = 6$ characteristic vibrational temperatures (K): 1360, 2330, 2330, 4800, 4880, 4880. The characteristic rotational temperatures given by McQuarrie are $\Theta_A = 13.6\ K$, $\Theta_B = 13.6\ K$, and $\Theta_C = 8.92\ K$. For NH_3, $\sigma = 3$.
Vibrational contribution: The table below shows a spreadsheet calculation of the vibrational terms inside the summation sign in Eq. (2-31).

$\Theta j/K$	$\Theta j/T$	S_{vib}
1207.91	4.051	0.08929
1850.16	6.205	0.01457
1850.16	6.205	0.01457
3688.19	12.370	0.00006
3821.36	12.817	0.00004
3821.36	12.817	0.00004
	Sum	0.1186

Rotational contribution:

$$\frac{S_r}{R} = \ln\left\{\frac{1}{3}\cdot\left[\frac{(298.15\text{ K})^3\pi c^3}{(13.6\text{ K})(13.6\text{ K})(8.92\text{ K})}\right]^{1/2}\right\} = 5.81593$$

Calculation using Eq. (2-31):

$$\frac{S^o_{298}}{R} = \frac{3}{2}\ln(6175\cdot 17) + 5.81593 + 0.1186 = 23.277 \quad \Delta H_{rxn} = \sum \nu_i(\Delta H^o_f)_i$$

$$S^o_{298} = 1.935 \times 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

The calculated value differs from the DIPPR® 801 recommended value of 1.9266×10^5 J/(kmol·K) by 0.5 percent.

Gibbs' Energy of Formation The standard Gibbs energy of formation is the Gibbs energy change upon formation of 1 mol of the compound in its standard state from its constituent elements in their standard states. The standard state Gibbs energy of formation ΔG^s_f uses the naturally occurring phase at 298.15 K and 1 bar as the standard state, while the ideal gas Gibbs energy of formation ΔG^o_f uses the compound in the ideal gas state at 298.15 K and 1 bar as the standard state. In both cases, the standard state for the elements is their naturally occurring state of aggregation at 298.15 K and 1 atm. Sources for data include DIPPR, TRC, JANAF, and Daubert and Danner, (Daubert, T. E., and R. P. Danner *Technical Data Book—Petroleum Refining*, 5th ed., American Petroleum Institute, Washington, extant 1994). The Gibbs energies of formation are related to the corresponding enthalpies and entropies of formation by

$$\Delta G^o_f = \Delta H^o_f - T\Delta S^o_f \qquad \text{and} \qquad \Delta G^s_f = \Delta H^s_f - T\Delta S^s_f \qquad (2\text{-}32)$$

and predicted values of ΔG^s_f and ΔG^o_f are obtained from Eq. (2-32) by estimating the enthalpies and entropies of formation as shown above.

LATENT ENTHALPY

Enthalpy of Vaporization The enthalpy (heat) of vaporization ΔH_v is the difference between the molar enthalpies of the saturated vapor and saturated liquid at a temperature between the triple point and critical point (at the corresponding vapor pressure). Variable ΔH_v is related to the vapor pressure P^* by the thermodynamically exact Clapeyron equation

$$\Delta H_v = -R\,\Delta Z_v \frac{d \ln P^*}{d(1/T)} = RT^2 \Delta Z_v \frac{d \ln P^*}{dT} \qquad (2\text{-}33)$$

where $\Delta Z_v = Z_G - Z_L$
Z_G = Z of saturated vapor
Z_L = Z of saturated liquid

Experimental heats of vaporization can be effectively correlated with

$$\Delta H_v = A(1 - T_r)^{B + CT_r + DT_r^2 + ET_r^3} \qquad (2\text{-}34)$$

A simple method for obtaining ΔH_v at one temperature from a known value at a reference temperature, say, at the normal boiling point, is to truncate Eq. (2-34) after the B term, set $B = 0.38$, and take a ratio of the ΔH_v values at the two conditions to give the Watson [Thek, R. E., and L. I. Stiel, *AIChE J.*, **12** (1966): 599; 13(1967): 626] correlation

$$\Delta H_v = \Delta H_{v,\text{ref}} \left(\frac{1 - T_r}{1 - T_{r,\text{ref}}}\right)^{0.38} \qquad (2\text{-}35)$$

If an accurate correlation for P^* and accurate values for Z_G and Z_L are available, Eq. (2-33) is the preferred method for obtaining enthalpies of vaporization. Otherwise, the CS methods shown below should be used.

Recommended Method 1 Vapor pressure correlation.
Classification: Extension of theory.
Expected uncertainty: Varies significantly with temperature and with the quality and temperature range of the vapor pressure data used in the correlation.
Applicability: Organic compounds for which group contributions have been regressed.
Input data: Correlations for P^*, Z_G, and Z_L. If $T_r < 0.8$, then Z_G can be set to 1.
Description: An expression for ΔH_v can be obtained from Eq. (2-33) by using an appropriate vapor pressure correlation. If one differentiates the Riedel vapor pressure correlation, Eq. (2-22), in accordance with Eq. (2-33), one obtains the heat of vaporization as

$$\Delta H_v = R\Delta Z_v\,(-B + CT + DET^{E+1}) \qquad (2\text{-}36)$$

The Z_G and Z_L values can be evaluated by using the methods given in the subsection on densities below.

Example Calculate ΔH_v for anisole at 452 K.
Input data: The vapor pressure coefficients in the DIPPR® 801 database, based on Eq. (2-22), are

$A = 128.06 \qquad B = -9307.7 \qquad C = -16.693 \qquad D = 0.014919 \qquad E = 1$

The vapor pressure at 452 K is

$$\ln\frac{P^*}{\text{Pa}} = 128.06 - \frac{9307.7}{452} - 16.693 \ln 452 + 0.014919(452)^1 = 12.155$$

$$P^* = \exp(12.155)\cdot\text{Pa} = 1.901 \times 10^5\text{Pa}$$

Determine ΔZ*:* Required data from the DIPPR® 801 database for this calculation are $T_c = 645.6$ K, $P_c = 4.25$ MPa, and $\omega = 0.35017$. These values are used to determine the reduced conditions and the values of Z_G and Z_L from the Lee-Kesler corresponding states method as discussed in the subsection on density.

$$T_r = \frac{452}{645.6} = 0.7 \qquad P_r = \frac{0.1901}{4.25} = 0.045$$

Interpolation of the P_r values in Tables 2-351 and 2-352 at a T_r of 0.7 gives

$$Z_G^{(0)} = 0.9904 + \frac{0.045 - 0.010}{0.050 - 0.010}(0.9504 - 0.9904) = 0.9554$$

$$Z_G^{(1)} = -0.0064 + \frac{0.045 - 0.010}{0.050 - 0.010}(-0.0507 + 0.0064) = -0.0452$$

$$Z_G = Z_G^{(0)} + \omega Z_G^{(1)} = 0.9554 + (0.35017)(-0.0452) = 0.94$$

At this low pressure, Z_L is very small compared to Z_G and may be neglected; so

$$\Delta Z_V = Z_G - Z_L = 0.94$$

Calculation using Eq. (2-36):

$$\Delta H_v = \left(8.314 \frac{\text{J}}{\text{mol·K}}\right)(0.94)[9307.7 - (16.693)(452) + (0.014919)(1)(452)^2]$$

$$= 37.59 \frac{\text{kJ}}{\text{mol·K}}$$

This value is 0.2 percent higher than the value of 37.51 kJ/(mol·K) obtained from the DIPPR® 801 database.

Recommended Method 2 Corresponding states correlation.
Reference: PGL5, p. 7.18.
Classification: Corresponding states.
Expected uncertainty: Less than about 6 percent.
Applicability: Organic compounds.
Input data: T_c, P_c, and ω.
Description: The following correlation is used:

$$\frac{\Delta H_v}{RT_c} = 7.08\tau^{0.354} + 10.95\omega\tau^{0.456} \qquad \text{where } \tau = 1 - T_r \tag{2-37}$$

Example Repeat the above calculation for anisole's ΔH_v at 452 K.
Input data: T_c = 645.6 K, P_c = 4.25 MPa, and ω = 0.35017.
Auxiliary quantities: From the previous example, the reduced temperature is

$$T_r = 0.7 \qquad \tau = 1 - 0.7 = 0.3$$

Calculation using Eq. (2-37):

$$\frac{\Delta H_v}{RT_c} = 7.08(0.3)^{0.354} + 10.95(0.35017)(0.3)^{0.456} = 6.838$$

$$\Delta H_v = (6.838)\left(8.314 \frac{\text{J}}{\text{mol·K}}\right)(645.6\text{ K}) = 36.70 \frac{\text{kJ}}{\text{mol·K}}$$

This value is 2.2 percent below the DIPPR® 801 recommended value of 37.51 kJ/(mol·K).

Recommended Method 3 Vetere method for ΔH_v at T_b.
Reference: Vetere, A., *Fluid Phase Equilib.*, **106** (1995): 1.
Classification: Corresponding states.
Expected uncertainty: About 4 percent.
Applicability: Valid only at the normal boiling point.
Input data: T_c, P_c, and T_b.
Description: The following correlation is used:

$$\frac{\Delta H_v}{RT_b} = \frac{\tau_b^{0.38}\left[\ln(P_c/\text{bar}) - 0.513 + \dfrac{0.5066\cdot\text{bar}}{P_c T_{br}^2}\right]}{\tau_b + F(1 - \tau_b^{0.38})\ln T_{br}} \tag{2-38}$$

where $\tau_b = 1 - T_{br}$

For most compounds, $F = 1$; compounds that dimerize (e.g., SO_2, NO, NO_2) and alcohols with more than two C atoms are assigned $F = 1.05$.

Example Calculate ΔH_v at the normal boiling point for acetaldehyde.
Input data: Recommended values from the DIPPR® 801 database are T_c = 466.0 K, P_c = 5.55 MPa, and T_b = 294.0 K.
Auxiliary quantities: From the previous example, the reduced temperature is

$$T_{br} = \frac{294}{466} = 0.631 \qquad \tau_b = 1 - T_{br} = 0.369 \qquad F = 1$$

Calculation using Eq. (2-38):

$$\frac{\Delta H_v}{RT_b} = \frac{(0.369)^{0.38}\left[\ln 55.5 - 0.513 + 0.5066/(55.5)(0.631)^2\right]}{(0.369) + [1 - (0.369)^{0.38}]\ln 0.631} = 10.785$$

$$\Delta H_v = (10.785)\left(8.314 \frac{\text{J}}{\text{mol·K}}\right)(294\text{ K}) = 26.36 \frac{\text{kJ}}{\text{mol·K}}$$

This value is 2.4 percent above the DIPPR® 801 recommended value of 25.73 kJ/(mol·K).

Enthalpy of Fusion The enthalpy (heat) of fusion ΔH_{fus} is the difference between the molar enthalpies of the equilibrium liquid and solid at the melting temperature and 1.0 atm pressure. There is no generally applicable, high-accuracy estimation method for ΔH_{fus}, but the GC method of Chickos can be used to obtain approximate results if the melting temperature is known.

Recommended Method Chickos method.
Reference: Chickos, J. S., et al., *J. Org. Chem.*, **56** (1991): 927.
Classification: QSPR and group contributions.
Expected uncertainty: Considerable variation but generally less than 50 percent.
Applicability: Only valid at the melting temperature. The method is based on the ΔS_{fus} between a solid at 0 K and the liquid at the T_m so no solid-solid transitions are taken into account. Values of ΔH_{fus} will be overestimated if there are solid-solid transitions for the actual material.
Input data: T_m and molecular structure.
Description:

$$\frac{\Delta H_{fus}}{\text{J/mol}} = \frac{\Delta S_{fus}}{\text{J/(mol·K)}}\left(\frac{T_m}{\text{K}}\right) = (T_m/\text{K})(a + b) \tag{2-39}$$

$$a = \begin{cases} 0 & \text{no nonaromatic rings} \\ 35.19N_R + 4.289(N_{CR} - 3N_R) & \text{nonaromatic rings} \end{cases} \tag{2-40}$$

$$b = \sum_{i=1}^{ng} Ng_i\,\Delta s_i + \sum_{j=1}^{ns} Ns_j Cs_j\,\Delta s_j + \sum_{k=1}^{nf} Nf_k Ct_k\,\Delta s_k \tag{2-41}$$

where
Ng_i = number of C—H groups of type i bonded to other carbon atoms
n_g = number of different nonring or aromatic C—H groups bonded to other carbon atoms
Ns_j = number of C—H groups of type j bonded to at least one functional group or atom
n_s = number of different nonring or aromatic C—H groups bonded to at least one functional group or atom
Nf_k = number of functional groups of type k
n_f = number of different functional groups or atoms
t = total number of functional groups or atoms with the exception that F atoms count as one regardless of number of occurences
Cs_j = value from Table 2-344 for C—H group j bonded to at least one functional group or atom
Ct_k = value from Table 2-345 for functional group k
N_R = number of nonaromatic rings
N_{CR} = number of —CH_2— groups in nonaromatic ring(s) required to form cyclic paraffin of same ring size(s)
Δs_i = contribution from Table 2-344 for group i
Δs_k = contribution from Table 2-345 for group k

TABLE 2-344 Cs (C—H) Group Values for Chickos Estimation* of ΔH_{fus}

Group	Description	*Cs*	Δ*s*	Group	Description	*Cs*	Δ*s*
$—CH_3$	methyl	1.0	18.33	$—CH_{Ar}$	aromatic C	1.0	6.44
$>CH_2$	methylene	1.0	9.41	$—C_{Ar}—$	ar. C bonded to paraffinic C	1.0	−10.33

				Total	3.51

$T_m = 258.52$ K from DIPPR® 801 database

$$\Delta H_{fus} = (T_m/\text{K})(a + b)\ \text{J/mol} = (258.52)(43.77 + 3.51)\ \text{J/mol} = 12.22\ \text{kJ/mol}$$

This value is 7 percent lower than the DIPPR® 801 recommended value of 13.13 kJ/mol.

(*c*) $t = 1 \quad N_R = 0 \quad a = 0$

Group	Description	*N*	*C*	Δs	Total
$—CH_3$	nonring (*Ng* type)	1	1	18.33	18.33
═CH–	nonring (*Ng* type)	1	1	4.85	4.85
═CH–	nonring (*Ns* type)	1	3.23	4.85	15.67
—CHO	aldehyde	1	1	19.66	19.66
				Total	58.51

$T_m = 158.38$ K from DIPPR® 801 database

$$\Delta H_{fus} = (T_m/\text{K})(a + b)\ \text{J/mol} = (158.38)(0 + 58.51)\ \text{J/mol} = 9.27\ \text{kJ/mol}$$

This value is 5 percent higher than the DIPPR® 801 recommended value of 8.86 kJ/mol.

Enthalpy of Sublimation The enthalpy (heat) of sublimation ΔH_{fus} is the difference between the molar enthalpies of the equilibrium vapor and solid along the sublimation curve below the triple point. The effects of pressure on ΔH_{fus} and melting temperature are very small so that T_t and the normal melting point are nearly equal and

$$\Delta H_{sub}(T_t) = \Delta H_v(T_t) + \Delta H_{fus}(T_t) \tag{2-42}$$

Equation (2-42) can be used to estimate ΔH_{sub} at the triple point if ΔH_v is accurately known at T_t. Because ΔH_v is usually obtained from Eq. (2-33), $\Delta H_v(T)$ correlations may be less accurate near T_t where $P^*(T_t)$ is very small and difficult to measure. In this case, it is better to estimate ΔH_{sub} directly by using the following recommended

method. Although Eqs. (2-33) and (2-34) apply to T_t, ΔH_{sub} is only a weak function of temperature and can generally be taken as a constant from the triple point temperature down to the first solid-solid phase transition.

Recommended Method Goodman method.

Reference: Goodman, B., et al., *Int. J. Thermophys.* **25** (2004): 337.

Classification: QSPR and group contributions.

Expected uncertainty: 6 percent.

Applicability: Organic compounds for which group contributions have been regressed.

Input data: Molecular structure and radius of gyration R_G.

Description:

$$\frac{\Delta H_{sub}(T_t)}{R\text{ K}} = 698.04 + 3.83798\times10^{12}\left(\frac{R_G}{\text{m}}\right) + \sum_{i=1}^{N} n_i a_i + \sum_{i=1}^{N} n_i^2 \beta_i + \sum_{i=1}^{N} \frac{n_i}{n_x} f_i \qquad (2\text{-}43)$$

where a_i = GC values from Table 2-346

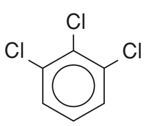
β_i = nonlinear corrections for $>CH_2$ and Ar—CH = groups

f_i = halogen corrections

n_x = total number of all halogen and hydrogen atoms attached to C and Si atoms

Example Calculate ΔH_{sub} and the solid vapor pressure for 1,2,3-trichlorobenzene at 301.15 K.

Structure:



Group contributions:

Linear groups			Nonlinear and correction terms			
Group	n_i	a_i	Group	n_i	β_i	f_i
Ar—CH═	3	626.7621	Ar—CH═	3	−2.21614	
Ar >C═	3	348.8092	—Cl	3		−1543.66
—Cl	3	1243.445	n_x	6		
$\sum_i n_i a_i$		6657.049				

Input data: The value of R_G from the DIPPR® 801 database is 4.455×10^{-10} m.

Calculation using Eq. (2-43):

$$\frac{\Delta H_{sub}(T_t)}{R\text{ K}} = 698.04 + (3.83798\times10^{12})(4.455\times10^{-10}) + 6657.049 + (3^2)(-2.21614) + \left(\frac{3}{6}\right)(-1543.66)$$

$$\Delta H_{sub}(T_t) = (8273.134\text{ K})\left(0.008314\frac{\text{kJ}}{\text{mol·K}}\right) = 68.78\frac{\text{kJ}}{\text{mol}}$$

The estimated value is 5.6 percent above the DIPPR® 801 recommended value of 65.11 kJ/mol.

Estimate the solid vapor pressure from Eq. (2-26): The solid vapor pressure at 301.15 K can be calculated from Eq. (2-26) by using the estimated ΔH_{sub}. Recommended values for T_t and P^*_t from the DIPPR® 801 database are 325.65 K and 182.957 Pa, respectively.

$$\ln\frac{P^*}{182.957\text{ Pa}} = \frac{68.78\text{kJ /mol}}{[0.008314\text{ kJ/(mol·K)}](325.65\text{ K})}\left(1-\frac{325.65}{301.15}\right) = -2.067$$

$$P^* = (182.957\text{ Pa})[\exp(-2.067)] = 23.16\text{ Pa}$$

The estimated value is 0.3 percent above the DIPPR® 801 recommended value of 23.09 Pa.

HEAT CAPACITY

Heat capacity C_P is defined as the energy required to change the temperature of a unit mass (specific heat) or mole (molar heat capacity) of the material by one degree. Typical units are J/(kg·K).

Gases The heat capacity of a gas is related rigorously to the ideal gas heat capacity C_P^o by

$$C_P = C_P^o - T\int_0^P \left(\frac{\partial^2 V}{\partial T^2}\right)_P dP \qquad (2\text{-}44)$$

The second term, giving the deviation of the real fluid heat capacity from the ideal gas value, can be neglected at low to moderate pressures, or it can be calculated directly from an appropriate EoS.

Ideal gas heat capacities are available from several sources (DIPPR, JANAF, TRC, and SWS). Two common correlating equations for C_P^o are the Aly-Lee [Aly, F. A., and L. L. Lee, *Fluid Phase Equilib.*, **6**

TABLE 2-346 Group Contributions and Corrections* for ΔH_{sub}

*Goodman, B., et al., *Int. J. Thermophys.*, **25** (2004): 337.

(1981): 169] equation

$$C_P^o = A_o + A_1\left[\frac{A_2/T}{\sinh(A_2/T)}\right]^2 + A_3\left[\frac{A_4/T}{\cosh(A_4/T)}\right]^2 \qquad (2\text{-}45)$$

and a polynomial form (generally fourth-order)

$$C_P^o = \sum_{i=0}^{4} A_i T^i \qquad (2\text{-}46)$$

Ideal gas heat capacities may also be estimated from several techniques, of which two of the most accurate and commonly used are recommended here.

Recommended Method 1 Statistical mechanics.

Reference: Rowley, R. L., *Statistical Mechanics for Thermophysical Property Calculations,* Prentice-Hall, Englewood Cliffs, N.J., 1994.

Classification: Theory and computational chemistry.

Expected uncertainty: 0.2 percent if vibrational frequencies (or their characteristic temperatures) are experimentally available; accuracy depends upon model chemistry if frequencies are determined from computational chemistry, but generally within 3 percent.

Applicability: Ideal gases.

Input data: $3n_A - 6 + \delta$ vibrational frequencies ν_j, or the corresponding characteristic vibrational temperatures Θ_j. The two are related by

$$\Theta_j = h\nu_j/k \qquad (2\text{-}47)$$

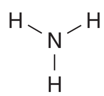
where n_A = number of atoms in molecule and $\delta = 1$ for linear molecules and 0 for nonlinear molecules.

Description: For harmonic frequencies, the rigorous temperature dependence of C_P^o is given by

$$\frac{C_P^o}{R} = \frac{8-\delta}{2} + \sum_{j=1}^{3n_A-6+\delta}\left(\frac{\Theta_j}{T}\right)^2\left[\frac{e^{\Theta_j/T}}{(e^{\Theta_j/T}-1)^2}\right] \quad \delta = \begin{cases}0 & \text{nonlinear}\\ 1 & \text{linear}\end{cases} \qquad (2\text{-}48)$$

Example Calculate the ideal gas heat capacity of ammonia at 300 K.

Structure:



Input data: McQuarrie (McQuarrie, D. A., *Statistical Mechanics*, Harper & Row, New York, 1976) gives the following $3m - 6 + \delta = 12 - 6 + 0 = 6$ characteristic vibrational temperatures (K): 1360, 2330, 2330, 4800, 4880, and 4880. Alternatively, a computational chemistry package gives the following *scaled* frequencies for HF/6-31G+ model chemistry (10^{13} Hz): 3.24, 4.97, 4.97, 9.90, 10.26, and 10.26.

Calculation: The table on the left uses the experimental Θ values to determine the individual terms in the summation of Eq. (2-48); the table on the right uses the scaled frequencies from computational chemistry software and Eq. (2-47) to obtain Θ values and the individual terms in Eq. (2-48).

From experimental frequencies:

$$C_P^o = \left(\frac{8}{2} + 0.2769\right)R = (4.2769)\left(8.3143\ \frac{\text{J}}{\text{mol·K}}\right) = 35.56\ \frac{\text{J}}{\text{mol·K}}$$

From computational chemistry frequencies:

$$C_P^o = \left(\frac{8}{2} + 0.197\right)R = (4.197)\left(8.3143\ \frac{\text{J}}{\text{mol·K}}\right) = 34.90\ \frac{\text{J}}{\text{mol·K}}$$

The value calculated from experimental frequencies is 0.1 percent lower than the DIPPR® 801 recommended value of 35.61 J/(mol·K); the value calculated from frequencies generated from computational chemistry software is 2.0 percent lower than the DIPPR® 801 value.

Recommended Method 2 Benson method as implemented in CHETAH program.

References: Benson, S. W., et al., *Chem. Rev.,* **69** (1969): 279; CHETAH Version 8.0: *The ASTM Computer Program for Chemical Thermodynamic and Energy Release Evaluation (NIST Special Database 16).*

Classification: Group contributions.

Expected uncertainty: 4 percent.

Applicability: Ideal gases of organic compounds.

Input data: Table 2-347 group values at the seven specified temperatures.

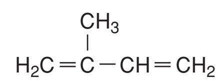
Description: Groups are summed at each individual temperature:

$$C_P^o = \sum_{i=1}^{N} n_i \cdot (C_p^o)_i \qquad (2\text{-}49)$$

where n_i = number of occurrences of group i and $(C_p^o)_i$ = individual group contribution. Either Eq. (2-45) or Eq. (2-46) can be used to interpolate between the discrete temperatures.

Example Calculate the ideal gas heat capacity of isoprene (2-methyl-1,3-butadiene) at 400 K.

Structure:



Group identification and values:

Group	No.	Value, J/(mol·K)	Contribution, J/(mol·K)
$=CH_2$	2	26.62	53.24
$=$C—(2C)	1	19.3	19.3
—CH_3-($=$C)	1	32.82	32.82
$=$CH-(C)	1	21.05	21.05
		Total	126.41

The value of 126.4 J/(mol·K) is 3.1 percent below the DIPPR® 801 recommended value of 130.4 J/(mol·K).

Liquids Liquid heat capacity increases with increasing temperature, although a minimum occurs near the triple point for many compounds. Usually liquid heat capacity is correlated as a function of temperature with a polynomial equation. A cubic equation is usually adequate.

Estimation of liquid heat capacity can be done by using a number of methods [Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619; Chueh, C. F., and A. C. Swanson, *Chem. Eng.*

Experimental frequencies

*Benson, S. W., et al., *Chem. Rev.*, **69** (1969): 279.
†CHETAH Version 8.0: *The ASTM Computer Program for Chemical Thermodynamic and Energy Release Evaluation (NIST Special Database 16).*

Prog., **69**, 7 (1973): 83; Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510; Tarakad, R. R., and R. P. Danner, *AIChE J.*, **23** (1977): 944] and thermodynamic differentiation. The most accurate and generally applicable method is that by Ruzicka and Domalski.

Recommended Method Ruzicka-Domalski.

References: Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619.

Classification: Group contributions.

Expected Uncertainty: 4 percent.

Applicability: Organic compounds for which group values are available.

Input data: Molecular structure and Table 2-348 values.

Description: Groups are summed to find the temperature coefficients for a cubic polynomial correlation:

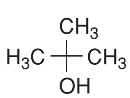
$$\frac{C_P}{R} = A + B\left(\frac{T}{100\text{ K}}\right) + D\left(\frac{T}{100\text{ K}}\right)^2 \tag{2-50}$$

$$A = \sum_{i=1}^{N} n_i a_i \qquad B = \sum_{i=1}^{N} n_i b_i \qquad D = \sum_{i=1}^{N} n_i d_i \tag{2-51}$$

where n_i = number of occurrences of group i and a_i, b_i, d_i = individual group contributions.

Example Estimate the liquid heat capacity for 2-methyl-2-propanol at 340 K.

Structure:



Group contributions:

Group	n_i	a_i	b_i	d_i
C—(3C,O) (alcohol)	1	−44.690	31.769	−4.8791
O—(H)(C)	1	12.952	−10.145	2.6261
C—(3H)(C)	3	3.8452	−0.33997	0.19489
	Sum	−20.202	20.604	−1.668

$$C_P = \left(8.3143\,\frac{\text{J}}{\text{mol·K}}\right)\left[-20.202 + 20.604\left(\frac{340}{100}\right) - 1.668\left(\frac{340}{100}\right)^2\right]$$

$$= 254.16\,\frac{\text{J}}{\text{mol·K}}$$

This value is 0.7 percent higher than the DIPPR® 801 recommended value of 252.40 J/(mol·K).

Solids Solid heat capacity increases with increasing temperature and is proportional to T^3 near absolute zero. The heat capacity at a solid-solid phase transition becomes large, and there can be a substantial difference in the heat capacity of the two equilibrium solid phases that exist on either side of the transition temperature. The heat capacity generally rises steeply with increasing temperature near the triple point.

For a quick estimation of solid heat capacity specifically at 298.15 K, the very simple modification of Kopp's rule [Kopp, H., *Ann. Chem. Pharm.* (*Liebig*), **126** (1863): 362] by Hurst and Harrison [Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21] can be used. At other temperatures and to obtain the temperature dependence of the solid heat capacity, the method given below by Goodman et al. should be used.

Recommended Method 1 Goodman method.

Reference: Goodman, B. T., et al., *J. Chem. Eng. Data*, **49** (2004): 24.

Classification: Group contributions.

Expected uncertainty: 10 percent.

Applicability: Organic compounds for which group values are available.

Input data: Molecular structure and Table 2-349 group values.

Description:

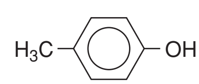
$$\frac{C_P}{\text{J/(mol·K)}} = \frac{A}{1000}\left(\frac{T}{\text{K}}\right)^{0.79267} \tag{2-52}$$

$$A = \exp\left(6.7796 + \sum_{i=1}^{N} n_i a_i + \sum_{i=1}^{N} n_i^2 \beta_i\right) \tag{2-53}$$

where n_i = number of occurences of group i
a_i = individual group contribution
β_i = nonlinear correction terms for chain and aromatic carbons

Example Estimate the solid heat capacity for *p*-cresol at 307.93 K.

Structure:



Group contributions:

Group	n_i	a_i	β_i
—CH_3	1	0.20184	0
Ar—CH═	4	0.082478	−0.00033
Ar >C═	2	0.012958	0
—OH	1	0.10341	0

From Eq. (2-53):

$$A = \exp[6.7796 + 0.20184 + (4)(0.082478) + (2)(0.012958) + 0.10341 + (4)^2(-0.00033)] = 1694.9$$

TABLE 2-348 Liquid Heat Capacity Group Parameters for Ruzicka-Domalski Method*

Table-specific nomenclature: Ct refers to a carbon atom with a triple bond; Cb refers to a carbon atom in benzene ring; =C refers to a carbon atom with a double bond; Cp refers to a carbon atom in a fused benzene ring; =C= refers to an allenic carbon atom.

*Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619.

From Eq. (2-52):

$$C_P = \frac{1694.9}{1000}(307.93)^{0.79267}\frac{\text{J}}{\text{mol·K}} = 159.1\frac{\text{J}}{\text{mol·K}}$$

This value is 2.5 percent higher than the DIPPR® 801 recommended value of 155.2 J/(mol·K).

Recommended Method 2 Modified Kopp's rule.
Reference: Kopp, H., *Ann. Chem. Pharm.* (*Liebig*), **126** (1863): 362; Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21.
Classification: Group contributions.
Expected uncertainty: 10 percent.
Applicability: 298.15 K; organic compounds that are solids at 298.15 K.
Input data: Compound chemical formula and element contributions of Table 2-350.
Description:

$$\frac{C_P}{\text{J/(mol·K)}} = \sum_{E=1}^{N} n_E \Delta_E \tag{2-54}$$

where N = number of different elements in compound
n_E = number of occurrences of element E in compound
Δ_E = contribution of element E from Table 2-350

Example Estimate the solid heat capacity at 298.15 K for dibenzothiophene.
Structure: $C_{12}H_8S$.
Group values from Table 2-350:

$$\Delta_C = 10.89 \qquad \Delta_H = 7.56 \qquad \Delta_S = 12.36$$

Calculation using Eq. (2-54):

$$C_p = (12)(10.89) + (8)(7.56) + (1)(12.36) = 203.52 \text{ J/(mol·K)}$$

This value is 2.5 percent higher than the DIPPR® 801 recommended value of 198.45 J/(mol·K).

Mixtures The heat capacity of liquid and vapor mixtures can be estimated as mole fraction averages of the pure-component values

$$C_{p,m} = \sum_{i=1}^{C} x_i C_{p,i} \tag{2-55}$$

This neglects the excess heat capacity, which if available can be added to the mole fraction average to improve the estimated value.

DENSITY

Density is defined as the mass of a substance per unit volume. Density is given in kg/m³ in SI units, but lb_m/ft^3 and g/cm³ are common AES and cgs units, respectively. Other commonly used forms of density include *molar density* (density divided by molecular weight) in kmol/m³, *relative density* (density relative to water at 15°C), and the older term *specific gravity* (density relative to water at 60°F). Often the inverse of density, *specific volume*, and the inverse of molar density, *molar volume*, are correlated and used to convey equivalent information.

Gases Gases/vapors are compressible and their densities are strong functions of both temperature and pressure. Equations of state (EoS) are commonly used to correlate molar densities or molar volumes. The most accurate EoS are those developed for specific fluids with parameters regressed from all available data for that fluid. Super EoS are available for some of the most industrially important gases and may contain 50 or more constants specific to that chemical. Different predictive methods may be used for gas densities depending upon the conditions:

1. At *very low densities* (high temperatures, generally above the critical, and very low pressures, generally below a few bar), the ideal gas EoS

$$Z \equiv \frac{PV}{RT} = 1 \tag{2-56}$$

may be applied.

2. At *moderate densities* (below 40 percent of the critical density), the virial equation truncated after the second virial coefficient

$$Z = 1 + \frac{B(T)}{V} \tag{2-57}$$

may be used. Second virial coefficients $B(T)$ are available in the DIPPR® 801 database for many chemicals and can be estimated for others by using the Tsonopoulos method.

*Goodman, B. T., W. V. Wilding, J. L. Oscarson, and R. L. Rowley, *J. Chem. Eng. Data*, **49** (2004): 24

Recommended Method Tsonopoulos method.

Reference: Tsonopoulos, C., *AIChE J.*, **20** (1974): 263; **21** (1975): 827; **24** (1978): 1112.

Classification: Corresponding states.

Expected uncertainty: 8 percent for $B(T)$.

Applicability: Nonpolar organic compounds and some classes of polar compounds.

Input data: Class of fluid, ω, P_c, T_c, and μ.

Description:

$$\frac{BP_c}{RT_c} = B^{(0)} + \omega B^{(1)} + B^{(2)} \tag{2-58}$$

where ω = acentric factor
P_c = critical pressure
T_c = critical temperature

$$B^{(0)} = 0.1445 - \frac{0.330}{T_r} - \frac{0.1385}{T_r^2} - \frac{0.0121}{T_r^3} - \frac{0.000607}{T_r^8} \tag{2-59}$$

$$B^{(1)} = 0.0637 + \frac{0.331}{T_r^2} - \frac{0.423}{T_r^3} - \frac{0.008}{T_r^8} \tag{2-60}$$

$$B^{(2)} = \frac{a}{T_r^6} - \frac{b}{T_r^8} \tag{2-61}$$

$$\mu_r = \left(\frac{\mu}{\text{D}}\right)^2 \left(\frac{P_c}{\text{bar}}\right)\left(\frac{T_c}{\text{K}}\right)^{-2} \tag{2-62}$$

where μ = dipole moment. The values of a and b used in Eq. (2-61) depend upon the class of fluid, as given in the table below:

Class	a	b
Nonpolar fluids	0	0
Ketones, aldehydes, nitriles, ethers, esters, NH_3, H_2S, HCN	$-21.4\mu_r - 4.308 \times 10^{19}\mu_r^8$	0
Monoalkylhalides, mercaptans, sulfides	$-2.188 \times 10^{16}\mu_r^4 - 7.831 \times 10^{19}\mu_r^8$	0
1-Alcohols except methanol	0.0878	$0.00908 + 69.57\mu_r$
Methanol	0.0878	0.0525

Example Estimate the molar volume of ammonia at 430 K and 2.82 MPa.

Input properties: Recommended values from the DIPPR® 801 database are T_c = 405.65 K, P_c = 11.28 MPa, μ = 1.469 D, and ω = 0.252608.

Reduced conditions:

$$T_r = (430 \text{ K})/(405.65 \text{ K}) = 1.06$$

$$P_r = (2.82 \text{ MPa})/(11.28 \text{ MPa}) = 0.25$$

$$\mu_r = (1.469)^2(112.8)/(405.65)^2 = 0.0014793$$

Second virial coefficient from Eqs. (2-59) to (2-61):

$$B^{(0)} = 0.1445 - 0.330/1.06 - 0.1385/(1.06)^2 - 0.0121/(1.06)^3$$

TABLE 2-350 Element Contributions to Solid Heat Capacity for the Modified Kopp's Rule*†

Element	Δ_E	Element	Δ_E	Element	Δ_E
C	10.89	Ba	32.37	Mo	29.44

B	10.10	Mn	28.06	All others	26.63

*Kopp, H., *Ann. Chem. Pharm.* (*Liebig*), **126** (1863): 362.
†Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21.

$- 0.000607/(1.06)^8 = - 0.301$

$B^{(1)} = 0.0637 + 0.331/(1.06)^2 - 0.423/(1.06)^3 - 0.008/(1.06)^8 = - 0.00189$

$a = (-21.4)(0.0014793) - (4.308 \times 10^{19})(0.0014793)^8 = - 0.033$

$b = 0$

$B^{(2)} = (-0.033)/(1.06)^6 = - 0.023$

From Eq. (2-58):

$BP_c/(RT_c) = - 0.301 - (0.252608)(0.00189) - 0.023 = - 0.324$

$B = (- 0.324)[0.008314 \text{ m}^3\cdot\text{MPa}/(\text{kmol}\cdot\text{K})](405.65 \text{ K})/(11.28 \text{ MPa})$

$= - 0.097 \text{ m}^3/\text{kmol}$

Molar volume from Eq. (2-56):

$$V = \frac{RT}{P}\left(1 + \frac{B}{V}\right) = \frac{\left(0.0083143 \frac{\text{m}^3\cdot\text{MPa}}{\text{kmol}\cdot\text{K}}\right)(430\ K)}{2.82 \text{ MPa}}\left(1 + \frac{-0.097 \frac{\text{m}^3}{\text{kmol}}}{V}\right)$$

$= 1.162 \text{ m}^3/\text{kmol}$

Note that the ideal gas value, 1.268 m^3/kmol, deviates by 9.1 percent from this more accurate value. The truncated virial EoS should be valid for this density since $\rho = V^{-1} = 0.86 \text{ kmol/m}^3$ is much less than 40 percent of the critical density (the DIPPR® 801 recommended value for the critical density is 13.8 kmol/m^3).

3. For *higher gas densities*, the Lee-Kesler method described below provides excellent predictions for nonpolar and slightly polar fluids. Extended four-parameter corresponding-states methods are available for polar and slightly associating compounds.

Recommended Method Lee-Kesler method.
Reference: Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.
Classification: Corresponding states.
Expected uncertainty: 1 percent except near the critical point where errors can be up to 30 percent.
Applicability: Nonpolar and moderately polar compounds. An extended Lee-Kesler method, not described here, may be used for polar and slightly associating compounds [Wilding, W. V., and R. L. Rowley, *Int. J. Thermophys.*, **8** (1986): 525].
Input data: T_c, P_c, ω, $Z^{(0)}$, $Z^{(1)}$.
Description:

$$Z = Z^{(0)} + \omega Z^{(1)} \qquad (2\text{-}63)$$

where Z = compressibility factor
$Z^{(0)}$ = compressibility factor of simple fluid obtained from Table 2-351.
$Z^{(1)}$ = deviation from simple fluid obtained from Table 2-352.

Analytical expressions for $Z^{(0)}$ and $Z^{(1)}$ can also be generated by using

$$Z^{(0)} = Z_0 \qquad Z^{(1)} = \frac{Z_1 - Z_0}{0.3978} \qquad (2\text{-}64)$$

where Z_0 and Z_1 are determined from

$$Z_i = \frac{P_rV_r}{T_r} = 1 + \frac{B}{V_r} + \frac{C}{V_r^2} + \frac{D}{V_r^5} + \frac{c_4}{T_r^3V_r^2}\left(\beta + \frac{\gamma}{V_r^2}\right)\exp\left(\frac{-\gamma}{V_r^2}\right) \qquad (2\text{-}65)$$

$$B = b_1 - \frac{b_2}{T_r} - \frac{b_3}{T_r^2} - \frac{b_4}{T_r^3}$$

$$C = c_1 - \frac{c_2}{T_r} + \frac{c_3}{T_r^2}$$

$$D = d_1 + \frac{d_2}{T_r}$$

as applied to the simple reference fluid and to the acentric reference fluid (*n*-octane), respectively. The constants for Eq. (2-65) for the two reference fluids are given in Table 2-353.

Example Estimate the molar volume of saturated decane vapor at 540.5 K.
Input properties: Recommended values from the DIPPR® 801 database are T_c = 617.7 K, P_c = 2.11 MPa, $P°$(540.5 K) = 0.6799 MPa (vapor pressure), and ω = 0.492328.
Reduced conditions:

$T_r = (540.5 \text{ K})/(617.7 \text{ K}) = 0.875$

$P_r = (0.6799 \text{ MPa})/(2.11 \text{ MPa}) = 0.322$

LK compressiblity factor: Since vapor phase values are needed, the appropriate values from Tables 2-351 and 2-352 that can be used to double-interpolate are

$Z^{(0)}$

$T_r\backslash P_r$	0.2	0.4
0.85	0.8810	(0.7222)
0.90	0.9015	0.7800

$Z^{(1)}$

$T_r\backslash P_r$	0.2	0.4
0.85	−0.0715	(−0.1503)
0.90	−0.0442	−0.1118

Double linear interpolation within these values gives $Z^{(0)}$ = 0.8058 and $Z^{(1)}$ = −0.1025.

From Eq. (2-63):

$Z = 0.8058 + (0.492328)(-0.1025) = 0.7553$

Note: If the analytical form available in Eq. (2-65) is used, the following more accurate values are obtained: $Z^{(0)}$ = 0.8131, $Z^{(1)}$ = − 0.1067, and Z = 0.7606.

Molar volume:

$$V = \frac{ZRT}{P} = \frac{(0.7553)\left(0.0083143 \frac{\text{m}^3\cdot\text{MPa}}{\text{kmol}\cdot\text{K}}\right)(540.5 \text{ K})}{0.6799 \text{ MPa}} = 4.992 \frac{\text{m}^3}{\text{kmol}}$$

4. *Cubic EoS* can be used to obtain both vapor and liquid densities as an alternative method to those mentioned above.

Recommended Method Cubic EoS.
Classification: Empirical extension of theory.
Expected uncertainty: Varies depending upon compound and conditions, but a general expectation is perhaps 10 to 20 percent.
Applicability: Nonpolar and moderately polar compounds.
Input data: T_c, P_c, ω.
Description: The more common cubic EoS can be written in the form

$$Z = \frac{V}{V-b} - \frac{V}{V^2 + \delta V + \varepsilon}\,\frac{a\,\alpha(T_r)}{RT} \qquad (2\text{-}66)$$

where a, b, δ, and ε are constants that depend upon the model EoS chosen, as does the temperature dependence of the function $\alpha(T_r)$. Definitions of these constants and $\alpha(T_r)$ for some of the more commonly used EoS models are shown in Table 2-354. The corresponding relations for many other EoS models in this same form are available [Soave, G., *Chem. Eng. Sci.*, **27** (1972): 1197]. The independent parameters a and b in these models can be regressed from experimental data to correlate densities or obtained from known critical constants to predict density data. In the latter case, the relationships between a and b and the critical constants shown in Table 2-354 were obtained from the critical point requirements

$$\left(\frac{\partial P}{\partial V}\right)_T\bigg|_{T=T_C} = 0 = \left(\frac{\partial^2 P}{\partial V^2}\right)_T\bigg|_{T=T_C} \qquad (2\text{-}67)$$

TABLE 2-351 Simple Fluid Compressibility Factors $Z^{(0)}$

Values in parentheses are for the opposite phase and may be used to interpolate to or near the phase boundary [PGL4; Wilding, W. V., J. K. Johnson, and R. L. Rowley, *Int. J. Thermophys.*, **8**(1987):717].

*Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

Of the cubic EoS given in Table 2-354, the Soave and Peng-Robinson are the most accurate, but there is no general rule for which EoS produces the best estimated volumes for specific fluids or conditions. The Peng-Robinson equation has been better tuned to liquid densities, while the Soave equation has been better tuned to vapor-liquid equilibrium and vapor densities. In solving the cubic equation for volume, a convenient initial guess to find the vapor root is the ideal gas value, while an initial value of 1.05b is convenient to locate the liquid root.

Example Estimate the molar density of liquid and vapor saturated ammonia at 353.15 K, using the Soave and Peng-Robinson EoS.

Required properties: Recommended values in the DIPPR® 801 database are

$$T_c = 405.65 \text{ K} \qquad P_c = 112.8 \text{ bar} \qquad \omega = 0.252608$$

$$P^* (353.15 \text{ K}) = 41.352 \text{ bar (vapor pressure at 353.15 K)}$$

EoS parameters (shown for Soave EoS):

$$a = \frac{0.42748(RT_c)^2}{P_c} = \frac{0.42748\left[\left(83.145\,\frac{\text{bar}\cdot\text{cm}^3}{\text{mol}\cdot\text{K}}\right)(405.65\text{ K})\right]^2}{112.8\text{ bar}}$$

$$= 4.311 \times 10^6 \frac{\text{cm}^6\cdot\text{bar}}{\text{mol}^2}$$

$$b = \frac{0.08664(RT_c)}{P_c} = \frac{0.08664\left(83.145\,\frac{\text{bar}\cdot\text{cm}^3}{\text{mol}\cdot\text{K}}\right)(405.65\text{ K})}{112.8\text{ bar}}$$

$$= 25.906\ \frac{\text{cm}^3}{\text{mol}}$$

$$T_r = (353.15\text{ K})/(405.65\text{ K}) = 0.871$$

$$\alpha = \{1 + [0.48 + (1.574)(0.252608) - (0.176)(0.252608)^2][1 - (0.871)^{0.5}]\}^2 = 1.119$$

Rearrange and solve Eq. (2-66) for V:

$$P = \frac{RT}{V-b} - \frac{a\alpha}{V(V+b)} \qquad \text{or} \qquad PV^3 - RTV^2 + (a\alpha - bRT - Pb^2)V - ab\alpha = 0$$

$$41.352\left(\frac{V}{\text{m}^3/\text{mol}}\right)^3 - \left(0.029\,\frac{\text{m}^3}{\text{mol}}\right)\left(\frac{V}{\text{m}^3/\text{mol}}\right)^2 + \left(4.037\times10^{-6}\ \frac{\text{m}^6}{\text{mol}^2}\right) \times \left(\frac{V}{\text{m}^3/\text{mol}}\right) - 1.25\times10^{-10} = 0$$

Vapor root (initial guess of V = 7.1 × 10^{-7} *m³/mol from ideal gas equation):*

$$V_{vap} = 5.395\times10^{-4}\ \text{m}^3/\text{mol} \qquad \text{and} \qquad \rho_{vap} = 1/V_{vap} = 1.854\ \text{kmol/m}^3$$

Liquid root (initial guess of V = 2.72×10^{-5} m³/mol *from 1.05b):*

$$V_{liq} = 4.441\times10^{-5}\ \text{m}^3/\text{mol} \qquad \text{and} \qquad \rho_{liq} = 1/V_{liq} = 22.516\ \text{kmol/m}^3$$

The corresponding values and equation for the Peng-Robinson EoS are

$$a = 4.611\times10^6\ \text{cm}^6\cdot\text{bar/mol}^2 \qquad b = 23.262\ \text{cm}^3/\text{mol}$$

$$\alpha = 1.103$$

$$P = \frac{RT}{V-b} - \frac{a\alpha}{V^2 + 2bV - b^2}$$

or

$$PV^3 + (bP - RT)V^2 + (a\alpha - 2bRT - 3Pb^2)V + (bP^3 + RTb^2 - ab\alpha) = 0$$

$$41.352\left(\frac{V}{\text{m}^3/\text{mol}}\right)^3 - \left(0.0284\,\frac{\text{m}^3}{\text{mol}}\right)\left(\frac{V}{\text{m}^3/\text{mol}}\right)^2 + \left(3.651\times10^{-6}\ \frac{\text{m}^6}{\text{mol}^2}\right) \times \left(\frac{V}{\text{m}^3/\text{mol}}\right) - 1.018\times10^{-10} = 0$$

$$V_{vap} = 5.286\times10^{-4}\ \text{m}^3/\text{mol and } \rho_{vap} = 1.892\ \text{kmol/m}^3$$

$$V_{liq} = 3.914\times10^{-5}\ \text{m}^3/\text{mol and } \rho_{liq} = 25.55\ \text{kmol/m}^3$$

The liquid density calculated from the Soave EoS is 24.2 percent below the DIPPR® 801 recommended value of 29.69 kmol/m³, while that calculated from the Peng-Robinson EoS is 13.9 percent below the recommended value.

TABLE 2-354 Relationships for Eq. (2-66) for Common Cubic EoS

Liquids For most liquids, the saturated molar liquid density ρ can be effectively correlated with

$$\rho = \frac{A}{B^{[1+(1-T/C)^D]}} \tag{2-68}$$

adapted from the Rackett prediction equation [Rackett, H. G., *J. Chem. Eng. Data*, **15** (1970): 514]. The regression constants *A, B*, and *D* are determined from the nonlinear regression of available data, while *C* is usually taken as the critical temperature. The liquid density decreases approximately linearly from the triple point to the normal boiling point and then nonlinearly to the critical density (the reciprocal of the critical volume). A few compounds such as water cannot be fit with this equation over the entire range of temperature.

The recommended method for estimation of saturated liquid density for pure organic compounds is the Rackett prediction method.

Recommended Method Rackett method.
Reference: Rackett, H. G., *J. Chem. Eng. Data*, **15** (1970): 514.
Classification: Corresponding states.
Expected uncertainty: 8 percent as purely predictive equation; 2 percent if Z_{RA} (see Description below) or some liquid density data are available.
Applicability: Saturated liquid densities of organic compounds.
Input data: T_c, P_c, and Z_c (or, equivalently, V_c).
Description: A predictive form of the equation is given by

$$\frac{1}{\rho} = V = \left(\frac{RT_c}{P_c}\right) Z_c^q \qquad \text{where } q = 1.0 + (1.0 - T_r)^{2/7} \tag{2-69}$$

A modification of the Rackett method by Spencer and Danner [Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236] replaces Z_c with an adjustable parameter Z_{RA}

$$\frac{1}{\rho} = V = \left(\frac{RT_c}{P_c}\right) Z_{RA}^q \tag{2-70}$$

to provide better estimations of liquid density away from the critical point [Eq. (2-70) gives the correct critical density only when $Z_{RA} = Z_c$]. An alternative to this modification when several liquid density data points are available is to replace the 2/7 power in *q* of Eq. (2-69) with an adjustable parameter. This generally provides good agreement with the experimental values and permits accurate extrapolation of the densities all the way to the critical point.

Example Estimate the saturated liquid density of acetonitrile at 376.69 K.
Required properties: The recommended values from the DIPPR® 801 database are

$$T_c = 545.5 \text{ K} \qquad P_c = 4.83 \text{ MPa} \qquad Z_c = 0.184$$

Calculate supporting quantities:

$$T_r = (376.69 \text{ K})/(545.5 \text{ K}) = 0.691$$
$$q = 1 + (1 - 0.691)^{2/7} = 1.715$$

Calculate saturated liquid density from Eq. (2-69):

$$\rho = \left[\frac{4.83\times10^6 \text{ Pa}}{\left(8.314 \frac{\text{Pa·m}^3}{\text{mol·K}}\right)(545.5 \text{ K})}\right](0.184)^{-1.715} = 19.42 \ \frac{\text{kmol}}{\text{m}^3}$$

This estimated value is 16.1 percent above the DIPPR® 801 recommended value of 16.726 kmol/m³.

Calculate ρ_{sat} *from Eq. (2-70):* Kratzke [Kratzke, H., and S. Muller, *J. Chem. Thermo.*, **17** (1985): 151] reported an experimental density of 18.919 kmol/m³ at 298.08 K. Use of this experimental value in Eq. (2-70) to calculate Z_{RA} gives

$$T_r = (298.08 \text{ K})/(545.5 \text{ K}) = 0.546 \qquad q = 1 + (1 - 0.546)^{2/7} = 1.798$$

$$Z_{RA} = \left[\frac{4.83\times10^6 \text{ Pa}}{\left(8314 \frac{\text{Pa·m}^3}{\text{kmol·K}}\right)(545.5 \text{ K})\left(18.919 \frac{\text{kmol}}{\text{m}^3}\right)}\right]^{1/1.798} = 0.202$$

$$\rho = \left[\frac{4.83\times10^6 \text{ Pa}}{\left(8.314 \frac{\text{Pa·m}^3}{\text{mol·K}}\right)(545.5 \text{ K})}\right](0.202)^{-1.715} = 16.577 \ \frac{\text{kmol}}{\text{m}^3}$$

The value obtained by the modified Rackett method is 0.9 percent below the DIPPR® 801 recommended value. Note, however, that with $Z_{RA} = 0.202$, Eq. (2-70) gives $\rho_c = 5.28$ kmol/m³ as opposed to the DIPPR® 801 recommended value of 5.79 kmol/m³. If the power is regressed from the Kratzke density, one obtains $q_1 = 0.452$ and $\rho = 15.68$ kmol/m³ (4 percent below the experimental value), while still retaining $\rho_c = 5.79$ kmol/m³.

Solids Solid density data are sparse and usually available only within a narrow temperature range. For most solids, density decreases approximately linearly with increasing temperature. Prediction of solid densities is an inexact science, but reasonable correlation has been found between the density of the liquid phase at the triple point and the solid that is stable at the triple point conditions.

Recommended Method Goodman method.
Reference: Goodman, B. T., et al., *J. Chem. Eng. Data*, **49** (2004): 1512.
Classification: Empirical correlation.
Expected uncertainty: 6 percent.
Applicability: Organic compounds; applicable to the stable solid phase at the triple point temperature T_t, to either the next solid-phase transition temperature or to approximately $0.3T_t$.
Input data: Liquid density at the triple point.
Description: The density for the solid phase that is stable at the triple point has been correlated as a function of temperature and the liquid density at T_t:

$$\rho_s = \left(1.28 - 0.16 \frac{T}{T_t}\right) \rho_L(T_t) \tag{2-71}$$

Example Estimate the density of solid naphthalene at 281.46 K.
Required properties: The recommended values from the DIPPR® 801 database for T_t and the liquid density at T_t are

$$T_t = 353.43 \text{ K} \qquad \rho_L(T_t) = 7.6326 \text{ kmol/m}^3$$

From Eq. (2-71):

$$\rho_s = \left(1.28 - 0.16 \frac{281.46 \text{ K}}{353.43 \text{ K}}\right)\left(7.6326 \frac{\text{kmol}}{\text{m}^3}\right) = 8.797 \ \frac{\text{kmol}}{\text{m}^3}$$

The estimated value is 4.3 percent lower than the DIPPR® 801 recommended value of 9.1905 kmol/m³.

Mixtures Both liquid and vapor densities can be estimated using pure-component CS and EoS methods by treating the fluid as a pseudo-pure component with effective parameters calculated from the pure-component parameters and using ad hoc mixing rules.

To apply the Lee-Kesler CS method to mixtures, pseudo-pure fluid constants are required. One of the simplest set of mixing rules for these quantities is [Prausnitz, J. M., and R. D. Gunn, *AIChE J.*, **4** (1958): 430, 494; Joffe, J., *Ind. Eng. Chem. Fundam.*, **10** (1971): 532]:

$$\overline{T}_c = \sum_{i=1}^{C} x_i T_{c,i} \tag{2-72}$$

$$\overline{P}_c = \frac{\sum_{i=1}^{C} x_i Z_{c,i}}{\sum_{i=1}^{C} x_i V_{c,i}} R\overline{T}_c \tag{2-73}$$

$$\overline{\omega} = \sum_{i=1}^{C} x_i \omega_i \tag{2-74}$$

The procedures are identical to those for pure components with the replacement of T_c, P_c, and ω with the effective mixture values calculated by using these equations.

To use a cubic EoS for a mixture, mixing rules are used to calculate effective mixture parameters in terms of the pure-component values. Although there are more complex mixing rules available that may improve prediction accuracy, the simplest forms are recommended here for their simplicity and reasonable accuracy without adjustable parameters:

$$\overline{b} = \sum_{i=1}^{C} x_i b_i \tag{2-75}$$

$$\overline{a\alpha} = \left[\sum_{i=1}^{C} x_i (a_i \alpha_i)^{1/2}\right]^2 \tag{2-76}$$

Mixture calculations are then identical to the pure-component calculations using these effective mixture parameters for the pure-component $a\alpha$ and b values.

The actual mixture second virial coefficient B_m is related to the pure-component values by

$$B_m = \sum_{i=1}^{C} \sum_{j=1}^{C} x_i x_j B_{ij} \qquad \text{where} \qquad B_{ii} = B_i \tag{2-77}$$

This requires calculation of all possible binary pair interaction virials (B_{ij}, $i \neq j$) for the mixture. Again the pure-component methods can be used to provide estimates of these values by using the following combining rules:

$$T_{c,ij} = \sqrt{T_{c,i} T_{c,j}} \qquad V_{c,ij} = \left(\frac{V_{c,i}^{1/3} + V_{c,j}^{1/3}}{2}\right)^3 \qquad Z_{c,ij} = \frac{Z_{c,i} + Z_{c,j}}{2} \tag{2-78}$$

$$\omega_{ij} = \frac{\omega_i + \omega_j}{2} \qquad P_{c,ij} = \frac{Z_{c,ij} R T_{c,ij}}{V_{c,ij}} \tag{2-79}$$

These interaction parameters are used in place of the corresponding pure-component parameters to determine the B_{ij} values.

The modified Rackett method has also been extended to liquid mixtures [Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236] using the following combining and mixing rules as modified by Li [Li, C. C., *Can. J. Chem. Eng.*, **19** (1971): 709]:

$$T_{c,ij} = \sqrt{T_{c,i} T_{c,j}} \qquad \phi_i = \frac{x_i V_{c,i}}{\sum_{j=1}^{C} x_j V_{c,j}} \qquad \overline{T}_c = \sum_{i=1}^{C} \sum_{j=1}^{C} \phi_i \phi_j T_{c,ij} \tag{2-80}$$

Recommended Method Spencer-Danner-Li mixing rules with Rackett equation.

References: Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236; Li, C. C., *Can. J. Chem. Eng.*, **19** (1971): 709.

Classification: Corresponding states.

Expected uncertainty: About 7 percent on average; higher near the T_c of any of the components.

Applicability: Saturated (at the bubble point) liquid mixtures.

Input data: T_c, V_c, and x_i.

Description: The predictive form of the equation is given by

$$\frac{1}{\rho} = V = R\left(\sum_{i=1}^{C} \frac{x_i T_{c,i}}{P_{c,i}}\right) \overline{Z}_{RA}^{q} \qquad q = 1.0 + (1.0 - T_r)^{2/7} \tag{2-81}$$

where

$$\overline{Z}_{RA} = 0.29056 - 0.08775 \sum_{i=1}^{C} x_i \omega_i \qquad \text{and} \qquad T_r = \frac{T}{\overline{T}_c} \tag{2-82}$$

Example Estimate the saturated liquid density of a liquid mixture of 50 mol % ethane(1) and 50 mol % *n*-decane(2) at 377.6 K.

Required properties: The recommended values from the DIPPR® 801 database for the required properties are as follows:

	T_c/K	V_c/(m³·kmol⁻¹)	P_c/ bar	ω
Ethane	305.32	0.1455	48.72	0.0995
Decane	617.7	0.617	21.1	0.4923

Auxiliary quantities from Eq. (2-80):

$$\phi_1 = \frac{(0.5)(0.1455)}{(0.5)(0.1455) + (0.5)(0.617)} = 0.191; \qquad \phi_2 = 0.809$$

$$T_{c,12} = \sqrt{(305.32\text{ K})(617.7\text{ K})} = 434.3\text{ K}$$

$$\frac{\overline{T}_c}{\text{K}} = \phi_1^2 T_{c,1} + 2\phi_1\phi_2 T_{c,12} + \phi_2^2 T_{c,2}$$

$$= (0.191)^2(305.32) + (2)(0.191)(0.809)(434.3) + (0.809)^2(617.7)$$

$$\overline{T}_c = 549.68\text{ K}$$

Calculations from Eqs. (2-81) and (2-82):

$$T_r = (377.6\text{ K})/(549.63\text{ K}) = 0.687$$

$$q = 1 + (1 - 0.687)^{2/7} = 1.718$$

$$\overline{Z}_{RA} = 0.29056 - 0.08775[(0.5)(0.0995) + (0.5)(0.4923)] = 0.2646$$

$$V = \left(0.08314 \frac{\text{m}^3\cdot\text{bar}}{\text{K}\cdot\text{kmol}}\right)\left[\frac{(0.5)(305.32\text{ K})}{48.72\text{ bar}} + \frac{(0.5)(617.7\text{ K})}{21.1\text{ bar}}\right](0.2646)^{1.718}$$

$$= 0.151 \frac{\text{m}^3}{\text{kmol}}$$

The experimental value [Reamer, H. H., and B. H. Sage, *J. Chem. Eng. Data*, **7** (1962): 161] is 0.149 m³/kmol, and the error in the estimated value is 1.3 percent.

VISCOSITY

Viscosity is defined as the shear stress per unit area at any point in a confined fluid, divided by the velocity gradient in the direction perpendicular to the direction of flow. The *absolute viscosity* η is the shear stress at a point, divided by the velocity gradient at that point. The SI unit of viscosity is Pa·s [1 kg/(m·s)], but the cgs unit of poise (P) [1 g/(cm·s)] is also commonly used. Because many common fluids have viscosities on the order of 0.01 P, the unit of centipoise (cP) is also frequently used (1 cP =1 mPa·s). The *kinematic viscosity* ν is defined as the ratio of the absolute viscosity to density at the same temperature and pressure. The SI unit for ν is m²/s, but again cgs units are very common and ν is often given in stokes (St) (1 cm²/s) or centistokes (cSt) (0.01 cm²/s).

Gases Experimental data for gases and vapors at low density are often correlated with

$$\eta^o = \frac{AT^B}{1 + C/T + D/T^2} \tag{2-83}$$

Over smaller temperature ranges, parameters C and D may not be necessary as ln η is often reasonably linear with ln T. Care should be taken in extrapolating using Eq. (2-83) as there can be unintended mathematical poles where the denominator approaches zero.

Numerous methods have been developed for estimation of vapor viscosity. For nonpolar vapors, the Yoon-Thodos CS method works well, but for polar fluids the Reichenberg method is preferred. Both methods are illustrated below.

Recommended Method Yoon-Thodos method.
Reference: Yoon, P., and G. Thodos, *AIChE J.*, **16** (1970): 300.
Classification: Corresponding states.
Expected uncertainty: 5 percent.
Applicability: Nonpolar and slightly polar organic vapors.
Input data: T_c, P_c, and M.
Description: The correlation for viscosity as a function of reduced temperature is

$$\frac{\eta^o}{\text{Pa·s}} = \frac{46.1T_r^{0.618} - 20.4\exp(-0.449T_r) + 19.4\exp(-4.058T_r) + 1}{2.173424 \times 10^{11}(T_c/\text{K})^{1/6}(M/\text{g·mol})^{-1}(P_c/\text{Pa})^{-2/3}} \tag{2-84}$$

Example Estimate the low-pressure vapor viscosity of propane at 353 K.
Required constants: The DIPPR® 801 database recommends the following values:

$T_c = 369.83$ K $\quad P_c = 4.248$ MPa $\quad M = 44.0956$ g/mol

Reduced temperature:

$$T_r = (353\text{ K})/(369.83\text{ K}) = 0.9545$$

Calculation using Eq. (2-84):

$$\frac{\eta^o}{\text{Pa · s}} = \frac{(46.1)(0.9545)^{0.618} - 20.4\exp[-0.449)(0.9545)] + 19.4\exp[-4.058(0.9545)] + 1}{(2.173424 \times 10^{11})(369.83)^{-1/2}(44.0956)^{-1/2}(4.248 \times 10^6)^{-2/3}}$$

$$= 9.84 \times 10^{-6}$$

The estimated value is 1.5 percent higher than the DIPPR® 801 recommended value of 9.70×10^{-6} Pa·s.

Recommended Method Reichenberg method.
Reference: Reichenberg, D., *AIChE J.*, **21** (1975): 181.
Classification: Group contributions and corresponding states.
Expected uncertainty: 5 percent.
Applicability: Nonpolar and polar organic and inorganic vapors.
Input data: T_c, P_c, M, μ, and molecular structure.
Description: The temperature dependence of the viscosity is given by

$$\frac{\eta^o}{\text{Pa·s}} = \frac{AT_r^2}{[1 + 0.36T_r(T_r - 1)]^{1/6}}\left[\frac{1 + 270(\mu_r^*)^4}{T_r + 270(\mu_r^*)^4}\right] \tag{2-85}$$

where the parameter A is determined from group contributions and the modified reduced dipole μ_r^* is found from

$$\mu_r^* = 52.46\mu_r \tag{2-86}$$

and Eq. (2.62).

For organic compounds, A is found from the group values C_i, listed in Table 2-355, using

$$A = 10^{-7}\frac{\left[\dfrac{M}{(\text{kg / kmol})}\right]^{1/2}(T_c/\text{K})}{\sum_{i=1}^{N} n_i C_i} \tag{2-87}$$

For inorganic gases, A is obtained from

$$A = 1.6104 \times 10^{-10}\left[\left(\frac{M}{\text{g/mol}}\right)^{1/2}\left(\frac{P_c}{\text{Pa}}\right)^{2/3}\left(\frac{T_c}{\text{K}}\right)^{-1/6}\right] \tag{2-88}$$

TABLE 2-355 Reichenberg* Group Contribution Values

Group	C_i	Group	C_i
—CH_3	9.04	—F	4.46
>CH_2	6.47	—Cl	10.06

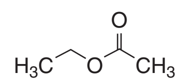
*Reichenberg, D., *AIChE J.*, **21** (1975): 181.

Example Estimate the low-pressure vapor viscosity of ethyl acetate at 401.25 K.
Required constants: The DIPPR® 801 database recommends the following values:

$M = 88.1051$ g/mol $\quad T_c = 523.3$ K $\quad P_c = 3.88$ MPa $\quad \mu = 1.78\ D$

Supporting quantities:
Structural groups:



Group	n_i	C_i	Contribution
$-CH_3$	2	9.04	18.08
>CH_2	1	6.47	6.47
—COO—	1	13.41	13.41
		Total	37.96

$$T_r = (401.25\text{ K})/(523.3\text{ K}) = 0.767$$

From Eqs. (2-62) and (2-86):

$$\mu_r^* = 52.46\frac{(1.78)^2(38.8)}{(523.3)^2} = 0.024$$

From Eq. (2-87):

$$A = 10^{-7}\frac{(88.1051)^{1/2}(523.3)}{37.96} = 1.294 \times 10^{-5}$$

Calculation using Eq. (2-84):

$$\frac{\eta^o}{\text{Pa·s}} = \frac{(1.294 \times 10^{-5})(0.767)^2}{[1 + (0.36)(0.767)(0.767 - 1)]^{1/6}}\ \frac{1 + (270)(0.024)^4}{0.767 + (270)(0.024)^4} = 1.003 \times 10^{-5}$$

The estimated value is 1.5 percent lower than the DIPPR® 801 recommended value of 1.018×10^{-5} Pa·s.

The dependence of viscosity upon pressure is principally a density effect. Estimation of vapor viscosity at elevated pressures is commonly done by correlating density deviations from the low-pressure values, which are in turn estimated by using the procedures mentioned above. Several methods are available, but the method developed by Jossi et al. and extended to polar fluids by Stiel and Thodos is relatively accurate and easy to apply.

Recommended Method Jossi-Stiel-Thodos Method.
References: Stiel, L. I., and G. Thodos, *AIChE J.*, **10** (1964): 26; Jossi, J. A., L. I. Stiel, and G. Thodos, *AIChE J.*, **8** (1962): 59.
Classification: Empirical correlation and corresponding states.
Expected uncertainty: 9 percent—often less for nonpolar gases, larger for polar gases.
Applicability: Nonassociating gases; $\rho_r < 2.6$.
Input data: M, T_c, P_c, Z_c, μ, η^o (low-pressure viscosity at same T may be estimated by using methods given above), and ρ (may be calculated from T and P by using density methods given above).

Description: Deviation of η from the low-pressure value η^o is given by one of the following correlations depending upon its polarity and reduced density range:

For nonpolar gases, $0.1 < \rho r < 3.0$:

$$\left[\left(\frac{\eta-\eta^o}{\text{mPa·s}}\right)\xi+1\right]^{1/4}=1.0230+0.23364\rho_r$$
$$+0.58533\rho_r^2-0.40758\rho_r^3+0.093324\rho_r^4 \qquad (2\text{-}89)$$

For polar gases, $\rho_r \le 0.1$:

$$\left(\frac{\eta-\eta^o}{\text{mPa·s}}\right)\xi=1.656\rho_r^{1.111} \qquad (2\text{-}90)$$

For polar gases, $0.1 < \rho_r \le 0.9$:

$$\left(\frac{\eta-\eta^o}{\text{mPa·s}}\right)\xi=0.0607(9.045\rho_r+0.63)^{1.739} \qquad (2\text{-}91)$$

For polar gases, $0.9 < \rho_r \le 2.2$:

$$\log\left\{4-\log\left[\left(\frac{\eta-\eta^o}{\text{mPa·s}}\right)\xi\right]\right\}=0.6439-0.1005\rho_r \qquad (2\text{-}92)$$

For polar gases, $2.2 < \rho r \le 2.6$:

$$\log\left\{4-\log\left[\left(\frac{\eta-\eta^o}{\text{mPa·s}}\right)\xi\right]\right\}=0.6439-0.1005\rho_r$$
$$-0.000475(\rho_r^3-10.65)^2 \qquad (2\text{-}93)$$

where $\rho_c = P_c/(Z_cRT_c)$ and

$$\xi=2173.4\left(\frac{T_c}{\text{K}}\right)^{1/6}\left(\frac{M}{\text{kg/kmol}}\right)^{-1/2}\left(\frac{P_c}{\text{MPa}}\right)^{-2/3} \qquad (2\text{-}94)$$

Example Estimate the vapor viscosity of CO_2 at 350 K and 20 MPa if $\eta^o = 0.0174$ mPa·s and $Z = 0.4983$ (estimated from Lee-Kesler method, see section on density).

Required properties: From the DIPPR® 801 database,

$M = 44.01$ kg/kmol $\quad T_c = 304.21$ K $\quad P_c = 7.383$ MPa

$Z_c = 0.274 \quad \mu = 0$ D (nonpolar)

Auxiliary quantities:

$$\xi=2173.4(304.21)^{1/6}(44.01)^{-1/2}(7.383)^{-2/3}=224.1$$

$$\rho_c=\frac{7.383\text{ MPa}}{0.274[8.314\text{ m}^3\text{Pa/(K·mol)}](304.21\text{ K})}=10.654\ \frac{\text{kmol}}{\text{m}^3}$$

$$\rho_r=\frac{\rho}{\rho_c}=\frac{P}{ZRT\rho_c}=\frac{20\text{ MPa}}{0.4983[8.314\text{ m}^3\text{·Pa/(K·mol)}](350\text{ K})(10.654\text{ m}^3\text{·kmol})}$$
$$=1.295$$

Calculation using Eq. (2-89) for nonpolar fluids:

$$\left[224.1\left(\frac{\eta-\eta^o}{\text{mPa·s}}\right)+1\right]^{1/4}=1.0230+0.23364(1.295)+0.58533(1.295)^2$$
$$-0.40758(1.295)^3+0.093324(1.295)^4=1.684$$

$$\eta=\frac{1.684^4-1}{224.1}\text{ mPa·s}+0.0174\text{ mPa·s}=0.0489\text{ mPa·s}$$

This differs from the experimental value of 0.0473 mPa·s by 3.4 percent.

Liquids Liquid viscosity can be correlated as a function of temperature for low pressures. Usually the correlation is based on the Andrade equation [Andrade, E. N. da C., *Nature*, **125** (1930): 309]

$$\ln\eta=A+\frac{B}{T} \qquad (2\text{-}95)$$

or an extension of it. For example, the DIPPR® 801 database uses the equation

$$\ln\eta=A+\frac{B}{T}+C\ln T+DT^E \qquad (2\text{-}96)$$

which is analogous to the Riedel [Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 83] vapor pressure equation.

Currently the most accurate method for predicting pure liquid viscosity is the following GC method.

Recommended Method Hsu method.

Reference: Hsu, H.-C., Y.-W. Sheu, and C.-H. Tu, *Chem. Eng. J.*, **88** (2002): 27.

Classification: Group contributions.

Expected uncertainty: 20 percent.

Applicability: Organic liquids; $T_r < 0.75$.

Input data: P_c and molecular structure.

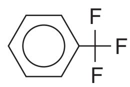
Description: The temperature dependence of the liquid viscosity is given by

$$\ln\left(\frac{\eta}{\text{mPa·s}}\right)=\sum_{i=1}^{N}a_i+T\sum_{i=1}^{N}b_i+\frac{\sum_{i=1}^{N}c_i}{T^2}+\left(\sum_{i=1}^{N}d_i\right)\ln\left(\frac{P_c}{\text{bar}}\right) \qquad (2\text{-}97)$$

where P_c is critical pressure and the coefficients *a, b, c,* and *d* are the sum of the group contributions obtained from Table 2-356.

Example Estimate the liquid viscosity of benzotrifluoride at 303.15 K.

Structural information:



Group	Number	a	$100b$	$0.0001c$	d
>C<	1	1.0031	−0.3677	−6.0316	1.1972
$(=CH—)_A$	5	−0.8570	−0.0098	2.4376	0.1311
$(=C<)_A$	1	0.7896	−0.0231	−0.9222	0.1928
$(—F)_3$	1	1.5394	0.8465	17.8121	−2.9915
	Total	−0.9529	0.4067	23.0463	−0.9460

Supporting values:

$$P_c = 32.1\text{ MPa}$$

Calculation using Eq. (2-97):

$$\frac{\eta}{\text{mPa·s}}=\exp\left[-0.9529+(0.004067)(303.15)+\frac{230463}{(303.15)^2}-0.9460\ln 32.1\right]$$
$$=0.610$$

The estimated value is 20 percent higher than the DIPPR® 801 recommended value of 0.509 mPa·s.

Liquid Mixtures Almost all methods for estimating liquid mixture viscosity interpolate between the pure-component values at the same temperature. The Grunberg-Nissan [Grunberg, L., and A. H. Nissan, *Nature*, **164** (1949): 799] equation

$$\ln\eta=\sum_i^C x_i\ln\eta_i+\frac{1}{2}\sum_{i=1}^{C}\sum_{j=1}^{C}x_ix_jG_{ij} \qquad (2\text{-}98)$$

is commonly used for nonaqueous mixtures. The parameter G_{ij} generally must be regressed from an experimental mixture viscosity. However, in the case of hydrocarbon mixtures G_{ij} can be set to zero with expected errors in the mixture viscosity of about 15 percent.

*Hsu, H.-C., Y.-W. Sheu, and C.-H. Tu, *Chem. Eng. J.*, **88** (2002): 27

Estimation of liquid mixture viscosity without any mixture data is difficult because the viscosity is strongly affected by large molecular size differences and strong cross interactions between the different types of molecules. Viscosity-composition plots for aqueous mixtures can have maxima or minima, and viscosities for these mixtures are particularly difficult to estimate. The UNIFAC-VISCO method described below can be used to predict liquid viscosity of organic mixtures without any mixture data. It is relatively successful even for large differences in molecular size, but it is currently limited in scope by the small number of group contributions available.

Recommended Method UNIFAC-VISCO method.

Reference: Chevalier, J. L., P. Petrino, and Y. Gaston-Bonhomme, *Chem. Eng. Sci.*, **43** (1988): 1303; Gaston-Bonhomme, Y., P. Petrino, and J. L. Chevalier, *Chem. Eng. Sci.*, **49** (1994): 1799.

Classification: Group contributions.

Expected uncertainty: 20 percent.

Applicability: Organic liquids.

Input data: Molecular structure; pure-component molar volumes and viscosities at the mixture temperature.

Description: The equations for this method are

$$\ln\left(\frac{\eta}{\text{mPa·s}}\right) = \sum_{i=1}^{\text{comp}} x_i \ln\left(\frac{\eta_i}{\text{mPa·s}}\cdot\frac{V_i}{V_m}\right) + \frac{g_c^E}{RT} - \frac{g_r^E}{RT} \qquad (2\text{-}99)$$

where V_m is the mixture molar volume and V_i is the pure-component molar volume of component i. The combinatorial and residual excess Gibbs energies are calculated exactly as in the UNIFAC method (see Sec. 13) with the exception that the group interactions ψ_{mm} are calculated by using

$$\Psi_{mn} = \exp\left(-\frac{\alpha_{mn}}{298.15}\right) \qquad (2\text{-}100)$$

The interaction parameters α_{mn} are obtained from Table 2-357.

Example Estimate the viscosity of a mixture of 51.13 mol % ethanol(1) and 48.87 mol % benzene(2) at 298.15 K.

Required input: Values from the DIPPR® 801 database for the pure components at 298.15 K are η_1 = 1.0774 mPa·s, η_2 = 0.5997 mPa·s, V_1 = 0.05862 m³/kmol, and V_2 = 0.08948 m³/kmol.

Groups, area fractions, volume fractions:

Group	R	Q	N_1	N_2
CH_3	0.9011	0.8480	1	0

OH	0.017	8.399	0.515	1.000

The α_{mn} values were obtained from Table 2-357, and Ψ_{mn} values were calculated from Eq. (2-100).

Group fractions in the mixture:

Group	N	X	XQ	Θ	ln γ
CH_3	0.5113	0.1145	0.097083	0.17370	0.293
CH_2	0.5113	0.1145	0.061822	0.11061	−0.873
CH_{ar}	2.9322	0.6565	0.262618	0.46988	0.066
OH	0.5113	0.1145	0.137382	0.24581	1.077
Sum	4.4661		0.558905		

Here
$$\Theta_m = \frac{X_m Q_m}{\sum_{i=1}^{4} X_i Q_i}$$

and

$$\ln \gamma_m = Q_m \left[1 - \ln \left(\sum_{i=1}^{4} \Theta_i \Psi_{i,m} \right) - \sum_{i=1}^{4} \frac{\Theta_i \Psi_{m,i}}{\sum_{j=1}^{4} \Theta_j \Psi_{j,i}} \right]$$

Group fractions in pure components:

Group	Ethanol N	X	XQ	Θ	ln γ
CH_3	1	0.3333	0.283	0.3277	0.5306
CH_2	1	0.3333	0.180	0.2087	−0.9405
CH_{ar}	0	0.0000	0.000	0.0000	0.2095
OH	1	0.3333	0.400	0.4637	0.6179
Sum	3		0.863		

Group	Benzene N	X	XQ	Θ	ln γ
CH_3	0	0	0	0	0.257
CH_2	0	0	0	0	−0.728
CH_{ar}	6	1	0.4	1	0.000
OH	0	0	0	0	2.270
Sum	6		0.4		

Here Θ and ln γ are defined by the same equations shown above for the mixture groups.

UNIFAC residual term:

$$\frac{g_r^E}{RT} = \sum_{i=1}^{2} x_i \left[\sum_{m=1}^{4} N_{m,i} (\ln\gamma_m - \ln\gamma_{m,i}) \right] = 0.3425$$

where N_m and $\ln \gamma_m$ refer to the mixture and $N_{m,i}$ and $\ln \gamma_{m,i}$ refer to the pure-component values.

Mixture volume:

$$V_m = \sum_{i=1}^{2} x_i V_i = 0.5113 \left(0.05862 \ \frac{\text{m}^3}{\text{kmol}}\right) + 0.4887 \left(0.08948 \ \frac{\text{m}^3}{\text{kmol}}\right)$$

$$= 0.07370 \ \frac{\text{m}^3}{\text{kmol}}$$

Using Eq. (2-99):

$$\ln \left(\frac{\eta}{\text{mPa·s}} \right) = 0.5113 \ln \left[1.0774 \left(\frac{0.05862}{0.07370} \right) \right] + 0.4887$$

$$\ln \left[0.5997 \left(\frac{0.08948}{0.07370} \right) \right] + 0.124 - 0.3425 = -0.4523$$

$$\eta = \exp(-0.4523) \text{ mPa·s} = 0.636 \text{ mPa·s}$$

The estimated value is 6.6 percent below the reported experimental value of 0.681 mPa·s [Kouris, S., and C. Panayiotou, *J. Chem. Eng. Data*, **34** (1989): 200].

THERMAL CONDUCTIVITY

Thermal conductivity k is a measure of the rate at which heat conducts through the material and is defined as the proportionality constant in Fourier's law of heat conduction that relates the gradient of temperature to the heat flux or flow per unit area. In SI units, it has the units of W/(m·K). The conduction mechanism in low-density media, gases,

is primarily via molecular collisions, and k increases with increasing temperature (increasing molecular velocity). In dense media such as liquids, the energy transfer by conduction occurs more efficiently through the attractive intermolecular potential wells between the molecules than through collisions. As a result, liquid thermal conductivity generally decreases with increasing temperature (except for water, aqueous solutions, and a few multihydroxy and multiamine compounds), corresponding to the decrease in density with increased temperature. Below or near the normal boiling point, the temperature dependence of liquid thermal conductivity is nearly linear for modest temperature ranges and can be represented by

$$k = A - BT \tag{2-101}$$

where B is generally in the range of 1×10^{-4} to 3×10^{-4} W/(m·K^2).

Gases Methods for estimating low-pressure gas thermal conductivities are based on kinetic theory and generally correlate the dimensionless group $kM/\eta C_v$ (M = molecular weight, η = viscosity, C_v = isochoric heat capacity) known as the Eucken factor. The method of Stiel and Thodos is recommended for pure nonpolar compounds, and the method of Chung is recommended for pure polar compounds.

Recommended Method Stiel-Thodos method.

Reference: Stiel, L. I., and G. Thodos, *AIChE J.*, **10** (1964): 26.

Classification: Empirical extension of theory.

Expected uncertainty: 15 percent.

Applicability: Pure nonpolar gases at low pressure.

Input data: M, T_c, η, and C_v.

Description: The following equations may be used depending upon the molecular shape:

$$\frac{kM}{\eta C_v} = 2.5 \qquad \text{monatomic} \tag{2-102}$$

$$\frac{kM}{\eta C_v} = 1.30 + \left(\frac{R}{C_v}\right)\left(1.7614 - \frac{0.3523}{T_r}\right) \qquad \text{linear molecules} \tag{2-103}$$

$$\frac{kM}{\eta C_v} = 1.15 + 2.033\left(\frac{R}{C_v}\right) \qquad \text{nonlinear molecules} \tag{2-104}$$

where η = viscosity at same conditions as desired for k. *Note:* Because this method is only applicable at low pressures, C_v may be calculated as $C_p^o - R$, where C_p^o is the ideal gas isobaric heat capacity.

Example Estimate the low-pressure thermal conductivity of toluene vapor at 500 K.

Required properties from the DIPPR® 801 database:

$T_c = 591.75$ K $\quad M = 92.138$ g/mol $\quad \eta\,(500\text{ K}) = 1.1408 \times 10^{-5}$ Pa·s

$C_v = C_p - R = (170.78 - 8.314)$ J/(mol·K) $= 162.47$ J/(mol·K)

Auxiliary quantities:

$T_r = 500/591.75 = 0.845 \qquad R/C_v = (8.314)/(162.47) = 0.0512$

From Eq. (2-104):

$$k = [1.15 + (2.033)(0.0512)]\left[\frac{(1.1408\times10^{-5}\text{Pa·s})\left(162.47\,\dfrac{\text{J}}{\text{mol·K}}\right)}{92.138\,\dfrac{\text{g}}{\text{mol}}}\right] = 25.2\,\frac{\text{mW}}{\text{m·K}}$$

The estimated value is 18 percent below the DIPPR® 801 recommended value of 30.76 mW/(m·K).

Recommended Method Chung-Lee-Starling method.

Reference: Chung, T.-H., L. L. Lee, and K. E. Starling, *Ind. Eng. Chem. Fundam.*, **23** (1984): 8.

Classification: Corresponding states.

Expected uncertainty: 15 percent.

Applicability: Pure organic gases at low pressure.

Input data: C_v, ω, T_c, M, and η.

Description: The following equations apply:

$$\frac{kM}{\eta C_v} = 3.75\,\Psi\left(\frac{R}{C_v}\right) \tag{2-105}$$

$$\Psi = 1 + \alpha\left(\frac{0.215 + 0.28288\alpha - 1.061\beta + 0.26665\gamma}{0.6366 + \beta\gamma + 1.061\alpha\beta}\right) \tag{2-106}$$

$$\alpha = \frac{C_v}{R} - 1.5 \qquad \beta = 0.7862 - 0.7109\omega + 1.3168\omega^2 \qquad \gamma = 2.0 + 10.5T_r^2 \tag{2-107}$$

Example Estimate the low-pressue thermal conductivity of naphthalene vapor at 500 K.

Required properties from the DIPPR® 801 database:

$T_c = 748.4$ K $\quad M = 128.17$ g/mol $\quad \omega = 0.30203$

$\eta(500\text{ K}) = 1.0173 \times 10^{-5}$ Pa·s

$C_v = C_p - R = (219.82 - 8.314)$ J/(mol·K) $= 211.51$ J/(mol·K)

Auxiliary quantities [Eqs. (2-106) and(2-107)]:

$T_r = 500/748.4 = 0.6681 \qquad R/C_v = (8.314)/(211.51) = 0.0393$

$\gamma = 2.0 + (10.5)(0.6681)^2 = 6.6866 \qquad \alpha = (0.0393)^{-1} - 1.5 = 23.9388$

$\beta = 0.7862 - (0.7109)(0.30203) + (1.3168)(0.30203)^2 = 0.6916$

$$\Psi = 1 + 23.9388 \times \left[\frac{0.215 + 0.28288(23.9388) - 1.061(0.6916) + 0.26665(6.6866)}{0.6366 + 0.6916(6.6866) + 1.061(23.9388)(0.6916)}\right] = 9.4273$$

From Eq. (2-105):

$$k = (3.75)(9.4273)\left[\frac{(1.1408\times10^{-5}\text{Pa·s})\left(8.314\,\dfrac{\text{J}}{\text{mol·K}}\right)}{128.17\,\dfrac{\text{g}}{\text{mol}}}\right] = 23.33\,\frac{\text{mW}}{\text{m·K}}$$

The estimated value is 1.0 percent above the DIPPR® 801 recommended value of 23.09 mW/(m·K).

Liquids The Baroncini method provides accurate liquid thermal conductivity estimates if the compound clearly belongs to one of the specific families designated by the correlation. The Sastri-Rao method is recommended for other specific families as listed in the discussion of the method given below. As a general method for estimating thermal conductivity of pure liquids at ambient pressure for all other compounds, the Missenard method is recommended.

Recommended Method Baroncini method.

Reference: Baroncini, C., et al., *Int. J. Thermophys.*, **2** (1981): 21.

Classification: Empirical correlation.

Expected uncertainty: 10 percent.

Applicability: Particularly accurate for the following families: acetates, aliphatic ethers, halogenated compounds, dicarboxylic acids, ketones, aliphatic alcohols, aliphatic acids, propionates and butyrates, and unsaturated aliphatic esters.

Input data: M, T_b (normal boiling point), T_c.

Description:

$$\frac{k}{\text{W/(m·K)}} = A\left(\frac{T_b}{K}\right)^{\alpha}\left(\frac{M}{\text{g/mol}}\right)^{-\beta}\left(\frac{T_c}{K}\right)^{-\gamma}\frac{(1-T_r)^{0.38}}{T_r^{1/6}} \tag{2-108}$$

where A, α, β, and γ are obtained from Table 2-358.

TABLE 2-358 Correlation Parameters for Baroncini et al. Method* for Estimation of Thermal Conductivity

Family	A	α	β	γ
Saturated hydrocarbons	0.00350	1.2	0.5	0.167
Olefins	0.0361	1.2	1	0.167
Cycloparaffins	0.0310	1.2	1	0.167
Aromatics	0.0346	1.2	1	0.167
Alcohols	0.00339	1.2	0.5	0.167
Organic acids	0.00319	1.2	0.5	0.167
Ketones	0.00383	1.2	0.5	0.167
Esters	0.0415	1.2	1	0.167
Ethers	0.0385	1.2	1	0.167
Refrigerants				
R20, R21, R22, R23	0.562	0	0.5	−0.167
Others	0.494	0	0.5	−0.167

*Baroncini, C., et al., *Int. J. Thermophys.*, **2** (1981): 21.

Example Estimate the thermal conductivity of liquid *p*-cresol at 400 K.
Required properties from DIPPR® 801 database:

$$M = 108.1378 \text{ g/mol} \qquad T_c = 704.65 \text{ K} \qquad T_b = 475.133 \text{ K}$$

Auxiliary properties:

$$T_r = T/T_c = (400 \text{ K})/(704.65 \text{ K}) = 0.5677$$

From Table 2-358 for alcohols:

$$A = 0.00339 \qquad \alpha = 1.2 \qquad \beta = \frac{1}{2} \qquad \gamma = 0.167$$

From Eq. (2-108):

$$\frac{k}{\text{W/(m·K)}} = (0.00339)(475.13)^{1.2}(108.1378)^{-1/2}(704.65)^{-0.167}$$

$$\frac{(1-0.5677)^{0.38}}{0.5677^{1/6}} = 0.142$$

The estimated value is 7.6 percent higher than the DIPPR® 801 recommended value of 0.132 W/(m·K).

Recommended Method Sastri-Rao method.
Reference: Sastri, S. R. S., and K. K. Rao, *Chem. Eng. J.*, **74** (1999): 161.
Classification: Group contributions and corresponding states.
Expected uncertainty: 10 percent.
Applicability: Particularly accurate for the following families: alkanes, alkenes, aromatic alcohols, cycloalkanes, epoxides, aliphatic acids, condensed rings.
Input data: T_c, T_b (normal boiling point), and molecular structure.
Description: The thermal conductivity at the normal boiling point k_b is calculated from the sum of the group contributions given in Table 2-359. This value is then scaled to the desired reduced temperature by using a factor α^β in which the power β is related to the fractional reduced temperature distance between the normal boiling point and the critical point as shown in the following equations:

$$k_b = \sum_{i=1}^{N} n_i \, \Delta k_i \qquad \beta = 1 - \left(\frac{1-T_r}{1-T_{br}}\right)^\gamma \qquad k = k_b \alpha^\beta \qquad (2\text{-}109)$$

where $\gamma = 1.23$ for alcohols and 0.2 for all other compounds and $\alpha = 0.856$ for alcohols and 0.16 for all other compounds.

TABLE 2-359 Sastri-Rao* Group Contributions for Liquid Thermal Conductivity at the Normal Boiling Point

Group	Δk_i (W/m·K)	Group	Δk_i (W/m·K)
Hydrocarbons		—COOH	0.0650
—CH_3	0.0545	—NH_2	0.0880
—CH_2—	−0.0008	—NH—	0.0065
>CH—	−0.0600	—NH— ring	0.0450
>C<	−0.1230	>N—	−0.0605
=CH_2	0.0545	>N— ring	0.0135
=CH—	0.0020	—CN	0.0645
=C<	−0.0630	—NO_2	0.0700
=C=	0.1200	—S	0.0100
ring[a]	0.1130	—F perfluoro	0.0568
Nonhydrocarbons		—F other	0.0510
—O—	0.0100	—Cl	0.0550
—OH primary[b]	0.0830	—Br	0.0415
—OH other	0.0680	—I	0.0245
>CO	0.0175	—H[c]	0.0675
>CHO	0.0730	3-ring	0.1500
—COO—	0.0070	other ring[d]	0.1100

Corrections for multigroup interactions	
Hydrocarbons with 4 or fewer carbon atoms	[e]$0.0150(5 - nC)$
Single CH_3 group + nonhydrocarbon groups other than COOH, Br, I[f]	0.0600
Two hydrocarbon + nonhydrocarbon groups other than COOH, Br, I[f]	0.0285
Unsaturated aliphatic compounds with three hydrocarbon groups	0.0285
Special groups $Cl(CH_2)_nCl$	0.0350
More than one nonhydrocarbon group with hydrocarbon groups	0.0095
Nonhydrocarbon groups but no hydrocarbon groups	0.1165

[a]All rings are treated as separate rings in polycyclic compounds.
[b]Used only for aliphatic primary alcohols and phenols having no branch chains.
[c]Used in methane, formic acid, formates, etc.
[d]Used for all rings in polycyclic compounds with at least one nonhydrocarbon ring.
[e]The number of carbon atoms is nC.
[f]Aliphatic nonhydrocarbon liquids such as methylformate, aceticanhydride, and ethylformate, having more than one type of nonhydrocarbon group and (1) one or two methyl groups or (2) one ethyl group only, require two correction factors. One is due to the hydrocarbon groups, and one is due to the presence of more than one type of nonhydrocarbon group
*SOURCE: Sastri, S. R. S., and K. K. Rao, *Chem. Eng. J.*, **74** (1999): 161.

Example Estimate the thermal conductivity of liquid methyl formate at 323 K.
Molecular structure:

Group contributions from Table 2-359:

Group	n_i	Δki	$n_i \Delta k_i$
—CH_3	1	0.0545	0.0545
—COO—	1	0.0070	0.0070
—H	1	0.0675	0.0675
Corrections for multigroup interactions			
Single CH3 group + nonhydrocarbon groups			0.0600
More than one nonhydrocarbon with hydrocarbon groups			0.0095
		Total	0.1985

Required input properties from DIPPR® 801 recommended values:

$$T_c = 487.2 \text{ K} \qquad T_b = 304.9 \text{ K}$$

$$T_r = T/T_c = 323/487.2 = 0.6630 \qquad T_{br} = 304.9/487.2 = 0.6258$$

From Eq. (2-109):

$$\alpha = 0.16 \qquad \gamma = 0.2 \qquad \text{(nonalcohol values)}$$

$$\beta = 1 - \left(\frac{1-0.633}{1-0.6257}\right)^{0.2} = 0.0207 \qquad k_b = 0.1985 \text{ W/(m·K)}$$

$$k = [0.1985 \text{ W/(m·K)}]\,(0.16)^{0.0207} = 0.1911 \text{ W/(m·K)}$$

The estimated value is 10.2 percent above the DIPPR® 801 recommended value of 0.1734 W/(m·K).

Recommended Method Missenard method.
Reference: Missenard, A., *Comptes Rendus*, **260** (1965): 5521.
Classification: Corresponding states.
Expected uncertainty: 20 percent.
Applicability: Organic compounds; nonassociating.
Input data: T_c, m (number of atoms in molecule), ρ_{273} (liquid density at 273.15 K), T_b, M, $C_{p,273}$ (liquid heat capacity at 273.15 K).
Description:

$$\frac{k_{273}}{\text{mW/(m·K)}} = \frac{8.4}{m^{1/4}} \cdot \left(\frac{T_b}{\text{K}}\right)^{1/2} \left(\frac{\rho_{273}}{\text{g/m}^3}\right)^{1/2} \left(\frac{M}{\text{g/mol}}\right)^{-1/2} \times \left[\frac{C_{p,273}}{\text{J/(mol·K)}}\right] \tag{2-110}$$

$$k = \frac{k_{273}[3 + 20(1 - T_r)^{2/3}]}{3 + 20(1 - T_{r,273})^{2/3}} \tag{2-111}$$

where $T_{r,273} = (273 \text{ K})/T_c$.

Example Estimate the thermal conductivity of *m*-xylene at 350 K.
Required properties from DIPPR® 801 database:

$$T_c = 617 \text{ K} \qquad m = 18 \qquad \rho_{273} = 7.6812 \text{ kmol/m}^3$$

$$T_b = 412.27 \text{ K} \qquad M = 106.165 \text{ kg/kmol} \qquad C_{p,273} = 200.64 \text{ kJ/(kmol·K)}$$

Auxiliary properties:

$$T_r = 350/617 = 0.5673 \qquad T_{br} = 412.27/617 = 0.6682$$

$$T_{r,273} = 273/617 = 0.4425$$

From Eq. (2-110):

$$\left(\frac{k_{273}}{\text{mW/(m·K)}}\right) = (8.4)(412.27)^{1/2}(0.007681)^{1/2}(106.165)^{-1/2}(200.64)(18)^{-0.25} = 141.3$$

From Eq. (2-111):

$$k = \frac{k_{273}[3 + 20(1 - T_r)^{2/3}]}{3 + 20(1 - T_{r,273})^{2/3}} = \frac{\left(141.3 \dfrac{\text{mW}}{\text{m·K}}\right)[3 + 20(1 - 0.5673)^{2/3}]}{3 + 20\,(1 - 0.4425)^{2/3}}$$

$$= 123.3 \frac{\text{mW}}{\text{m·K}}$$

The estimated value is 4.5 percent above the DIPPR® 801 recommended value of 118.0 mW/(m·K).

Liquid Mixtures The thermal conductivity of liquid mixtures generally shows a modest negative deviation from a linear mass-fraction-weighted average of the pure-component values. Although more complex methods with some improved accuracy are available, two simple methods are recommended here that require very little additional information. The first method applies only to binary mixtures while the second can be used for multiple components.

Recommended Method Filippov correlation.
References: Filippov, L. P., *Vest. Mosk. Univ., Ser. Fiz. Mat. Estestv. Nauk*, **10** (1955): 67; Filippov, L. P., and N. S. Novoselova, Sugden, *Vest. Mosk. Univ., Ser. Fiz. Mat. Estestv. Nauk,* **10** (1955): 37.
Classification: Empirical correlation.
Expected uncertainty: 4 to 8 percent.
Applicability: Binary liquid mixtures.
Input data: Pure-component thermal conductivities k_i at mixture conditions; w_i.
Description: The mixture thermal conductivity is calculated from the pure-component values using

$$k = w_1k_1 + w_2k_2 - 0.72w_1w_2|k_2 - k_1| \tag{2-112}$$

where w_i is the mass fraction of pure fluid i.

Recommended Method Li correlation.
References: Li, C. C., *AIChE J.*, **22** (1976): 927.
Classification: Empirical correlation.
Expected uncertainty: 4 to 8 percent.
Applicability: Liquid mixtures.
Input data: Pure-component thermal conductivities k_i at mixture conditions; $\rho_{L,i}$
Description: The mixture thermal conductivity is correlated as a function of the mixture volume fractions ϕ_i:

$$k = \sum_{i=1}^{C} \sum_{j=1}^{C} \phi_i \phi_j \frac{2k_ik_j}{k_i + k_j} \tag{2-113}$$

$$\text{where } \phi_i = \frac{x_i \rho_{L,i}^{-1}}{\sum_{j=1}^{C} x_j \rho_{L,j}^{-1}}$$

Example Estimate the thermal conductivity of a mixture containing 30.2 mol % diethyl ether(1) and 69.8 mol % methanol(2) at 273.15 K and 0.1 MPa, using the Filippov and Li correlations.
Auxiliary data: The pure-component thermal conductivities and molar densities at 273.15 K recommended in the DIPPR® 801 database are

$$k_1 = 0.1383 \text{ W/(m·K)} \qquad \rho_1 = 9.9335 \text{ kmol/m}^3 \qquad M_1 = 74.1216 \text{ kg/kmol}$$

$$k_2 = 0.2069 \text{ W/(m·K)} \qquad \rho_2 = 25.371 \text{ kmol/m}^3 \qquad M_2 = 32.0419 \text{ kg/kmol}$$

The mass fractions corresponding to the mole fractions given above are

$$w_1 = 0.5 \qquad w_2 = 0.5$$

The volume fractions are

$$\phi_1 = \frac{(0.302)(9.9335)^{-1}}{(0.302)(9.9335)^{-1} + (0.698)(25.371)^{-1}} = 0.525 \qquad \phi_2 = 0.475$$

Calculation using Eq. (2-112):

$$k = [(0.5)(0.1383) + (0.5)(0.2069) - (0.72)(0.5)(0.5)|0.2069 - 0.1383|]\ \frac{\text{W}}{\text{m·K}}$$

$$= 0.160\ \text{W/(m·K)}$$

Calculation using Eq. (2-113):

$$k = \left[(0.525)^2(0.1383) + 2\cdot\frac{(0.525)(0.475)(2)(0.1383)(0.2069)}{0.1383 + 0.2069} + (0.475)^2(0.2069)\right]\frac{\text{W}}{\text{m·K}}$$

$$= 0.167\ \text{W/(m·K)}$$

The Filippov value is 7.5 percent lower than the experimental value of 0.173 W/(m·K) [Jamieson, D. T., and B. K. Hastings, *Thermal Conductivity*, *Proceedings of the Eighth Conference,* C. Y. Ho and R. E. Taylor, eds., Plenum Press, New York, 1969]; the Li value is 3.5 percent lower than the experimental value.

Solids There is no reliable method for estimating solid thermal conductivity at this time.

SURFACE TENSION

The surface layer at a vapor-liquid interface is in tension and will contract to minimize the surface area. Qualitatively, the surface tension is due to the larger attractive forces that molecules at the interface experience from molecules in the dense liquid phase than from those in the low-density gas phase. Quantitatively, *surface tension* is defined as the force in the surface plane per unit length. Jasper [Jasper, J. J., *J. Phys. Chem. Ref. Data*, **1** (1972): 841] has made a critical evaluation of experimental surface tension data for approximately 2200 pure chemicals and correlated surface tension σ (mN/m = dyn/cm) with temperature as

$$\sigma = A - BT$$

Jasper's evaluation also includes values of A and B for most of the tabulated chemicals. Surface tension decreases with increasing temperature and increasing pressure.

Pure Liquids An approach suggested by Macleod [Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38] and modified by Sugden [Sugden, S. J., *Chem. Soc.*, **125** (1924): 32] relates σ to the liquid and vapor *molar* densities and a temperature-independent parameter called the parachor **P**

$$\frac{\sigma}{\text{mN/m}} = \left[\mathbf{P}\cdot\left(\frac{\rho_L - \rho_V}{10^3\ \text{kmol/m}^3}\right)\right]^4 \qquad (2\text{-}114)$$

where ρ_L and ρ_V are the saturated molar liquid and vapor densities, respectively. At low temperatures, where $\rho_L >> \rho_V$, the vapor density can be neglected, but at higher temperatures the density of both phases must be calculated. At the critical point the surface tension is zero as $\rho_L = \rho_V$. Quayle [Quayle, O. R., *Chem. Rev.*, **53** (1953): 439] proposed a group contribution method for estimating **P** that has been improved in recent years by Knotts et al. [Knotts, T. A., et. al., *J. Chem. Eng. Data*, **46** (2001): 1007]. This method using **P** is recommended when groups are available; otherwise, the Brock-Bird [Brock, J. R., and R. B. Bird, *AIChE J.*, **1** (1955): 174] corresponding-states method as modified by Miller [Miller, D. G., *Ind. Eng. Chem. Fundam.*, **2** (1963): 78] may be used to estimate surface tension for compounds that are not strongly polar or associating.

Recommended Method Parachor method.

References: Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38; Sugden, S. J., *Chem. Soc.*, **125** (1924): 32; Knotts, T. A., et al., *J. Chem. Eng. Data*, **46** (2001): 1007.

Classification: Group contributions and QSPR.

Expected uncertainty: 4 percent.

Applicability: Organic compounds for which group values are available.

Input Data: ρ_L, molecular structure, and Table 2-360.

Description: Equation (2-114) is used with **P** calculated from

$$\mathbf{P} = \sum_{i=1}^{N} n_i\,\Delta\mathbf{P}_i \qquad (2\text{-}115)$$

Group values for the parachor are given in Table 2-360.

Example Estimate the surface tension of ethylacetylene at 237.45 K.
Structure:

Group	n_i	$\Delta\mathbf{P}_i$	$n_i\,\Delta\mathbf{P}_i$
≡CH	1	43.64	43.64
≡C—	1	28.64	28.64
>CH_2 (n = 1–11)	1	39.92	39.92
CH_3	1	55.25	55.25
		Total	167.45

Required properties: The DIPPR® 801 database gives ρ_L = 13.2573 kmol/m^3 at 237.45 K.

Calculation using Eq. (2-114):

$$\sigma = \left[(167.45)\left(\frac{13.2573}{1000}\right)\right]^4 \frac{\text{mN}}{\text{m}} = 0.02429\ \frac{\text{N}}{\text{m}}$$

The estimated value is 0.9 percent above the DIPPR® 801 recommended value of 0.02407 N/m.

Recommended Method Brock-Bird method.

Reference: Brock, J. R., and R. B. Bird, *AIChE J.*, **1** (1955): 174; Miller, D. G., *Ind. Eng. Chem. Fundam.*, **2** (1963): 78.

Classification: Corresponding states.

Expected uncertainty: 5 percent.

Applicability: Nonpolar and moderately polar organic compounds.

Input data: T_c, P_c, and T_b.

Description:

$$\frac{\sigma}{\text{mN/m}} = (5.553\times10^{-5})\left(\frac{P_c}{\text{Pa}}\right)^{2/3}\left(\frac{T_c}{\text{K}}\right)^{1/3} F(1-T_r)^{11/9} \qquad (2\text{-}116)$$

where

$$F = \frac{T_{br}[\ln(P_c/\text{Pa}) - 11.5261]}{1 - T_{br}} - 1.3281 \qquad (2\text{-}117)$$

Example Estimate the surface tension for ethyl mercaptan at 303.15 K.
Required properties from DIPPR® 801:

$$T_c = 499.15\ \text{K} \qquad P_c = 5.49\times10^6\ \text{Pa} \qquad T_b = 308.15\ \text{K}$$

Supporting quantities:

$$T_r = (303.15\ \text{K})/(499.15\ \text{K}) = 0.6073$$

$$T_{br} = (308.15\ \text{K})/(499.15\ \text{K}) = 0.6173$$

$$F = \{0.6173\,[\ln(5.49\times10^6) - 11.5261]/(1-0.6173)\} - 1.3281 = 5.113$$

[from Eq. (2-117)]

From Eq. (2-116):

$$\sigma = (5.553\times10^{-5})(5.49\times10^6)^{2/3}(499.15)^{1/3}(5.113)(1-0.6073)^{11/9}\ \text{mN/m}$$

$$= 22.36\ \text{mN/m}$$

The estimated value is 1.4 percent lower than the DIPPR® 801 recommended value of 22.68 mN/m.

*Knotts, T. A., et al., *J. Chem. Eng. Data*, **46** (2001): 1007.

Liquid Mixtures Compositions at the liquid-vapor interface are not the same as in the bulk liquid, and so simple (bulk) composition-weighted averages of the pure-fluid values do not provide quantitative estimates of the surface tension at the vapor-liquid interface of a mixture. The behavior of aqueous mixtures is more difficult to correlate and estimate than that of nonpolar mixtures because small amounts of organic material can have a pronounced effect upon the surface concentrations and the resultant surface tension. These effects are usually modeled with thermodynamic methods that account for the activity coefficients. For example, a UNIFAC method [Suarez, J. T. C. Torres-Marchal, and P. Rasmussen, *Chem. Eng. Sci.*, **44** (1989): 782] is recommended and illustrated in PGL5. For nonaqueous systems the extension of the parachor method, used above for pure fluids, is a simple and reasonably effective method for estimating σ for mixtures.

Recommended Method Parachor correlation.

Reference: Hugill, J. A., and A. J. van Welsenes, *Fluid Phase Equil.*, **29** (1986): 383; Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38; Sugden, S. J., *Chem. Soc.*, **125** (1924).

Classification: Corresponding states.

Expected uncertainty: 3 to 10 percent.

Applicability: Nonaqueous mixtures.

Input data: Liquid and vapor ρ at mixture T; parachors of pure components; x_i.

Description:

$$\frac{\sigma_m}{\text{mN/m}} = \left(\mathbf{P}_{L,m} \frac{\rho_{L,m}}{10^3 \text{kmol/m}^3} - \mathbf{P}_{V,m} \frac{\rho_{V,m}}{10^3 \text{kmol/m}^3} \right)^4 \qquad (2\text{-}118)$$

where σ_m = surface tension of the mixture
$\mathbf{P}_{L,m}$ = parachor of liquid mixture
$\mathbf{P}_{V,m}$ = parachor of vapor mixture
$\rho_{L,m}$ = liquid mixture molar density
$\rho_{V,m}$ = vapor mixture molar density

The following definitions are used for the liquid and vapor mixture parachors:

$$\mathrm{P}_{L,m} = \frac{1}{2}\sum_{i=1}^{C}\sum_{j=1}^{C} x_i x_j (\mathbf{P}_i + \mathbf{P}_j) \qquad \mathbf{P}_{V,m} = \frac{1}{2}\sum_{i=1}^{C}\sum_{j=1}^{C} y_i y_j (\mathbf{P}_i + \mathbf{P}_j) \tag{2-119}$$

where x_i is the mole fraction of component i in the liquid and y_i is the mole fraction of component i in the vapor.

Note that ρ_V is generally very small compared to ρ_L at temperatures substantially lower than T_c and can often be neglected.

Example Estimate the surface tension for a 16.06 mol % n-pentane(1) + 83.94 mol % dichloromethane(2) mixture at 298.15 K.

Required properties from DIPPR® 801:

	P	ρ_L/(kmol·m^{-3}) at 298.15 K
n-Pentane	231.1	8.6173
Dichloromethane	146.6	15.5211

Mixture parachor from Eq. (2-119) and mixture density:

$$\mathbf{P}_{L,m} = (0.1606)^2(231.1) + (0.1606)(0.8394)(231.1 + 146.6)$$
$$+ (0.8394)^2(146.6) = 160.17$$

$$\rho_{L,m} = \left(\sum_{i=1}^{C}\frac{x_i}{\rho_i}\right)^{-1} = \left(\frac{0.1606}{8.6173} + \frac{0.8394}{15.5211}\right)^{-1}\frac{\text{kmol}}{\text{m}^3} = 13.752\,\frac{\text{kmol}}{\text{m}^3}$$

Calculation using Eq. (2-118): Because the temperature is low, the density of the vapor can be neglected, and

$$\frac{\sigma_m}{\text{mN/m}} = [(160.17)(0.013752)]^4 = 23.54\,\frac{\text{mN}}{\text{m}}$$

The estimated value is 2.9 percent below the experimental value of 24.24 mN/m reported by De Soria et al. [De Soria, M. L. G., et al., *J. Colloid Interface Sci.*, **103** (1985): 354].

FLAMMABILITY PROPERTIES

Flash points, lower and upper *flammability limits*, and *autoignition temperature* are important properties for determining safe operating limits when processing organic compounds. As with any property, experimental values are preferable to predicted values, and prediction techniques for these properties are only modestly accurate.

The flash point is the lowest temperature at which a liquid gives off sufficient vapor to form an ignitable mixture with air near the surface of the liquid or within the vessel used. ASTM test methods include procedures using a closed-cup apparatus (ASTM D 56, ASTM D 93, and ASTM D 3828), which is preferred, and an open-cup apparatus (ASTM D 92 and ASTM D 1310). Closed-cup values are typically lower than open-cup values. When several values are available, the lowest reasonable temperature is usually accepted in order to ensure safe operations.

The lower and upper flammability limits are the boundary-line equilibrium mixtures of vapor or gas with air, which if ignited will just propagate a flame away from the ignition source. Each of these limits has a temperature at which the flammability limits are reached. The lower flammability limit temperature corresponds approximately to the flash point, but since the flash point is determined with downward flame propagation and nonuniform mixtures and the lower flammability temperature is determined with upward flame propagation and unifrom vapor mixtures, the measured lower flammability temperature is often somewhat lower than the flash point.

The autoignition temperature is the minimum temperature for a substance to initiate self-combustion in air in the absence of an ignition source.

Recommended Methods Flash point: Thornton method.
Reference: As described by N. Y. Shebeko, A. V. Ivanov, and E. N. Alekhina, "Calculation of Flash Points and Ignition Temperatures of Organic Compounds," *Soviet Chem. Ind.* **16**(1984):1371.
Classification: Atomic contributions.
Expected uncertainty: 5 K.
Applicability: Organic compounds.
Input data: Number of carbon, hydrogen, sulfur, halogen, and oxygen atoms; vapor pressure correlation.
Description: A simple atom contribution method is given by

$$P^* - \frac{P_{sys}}{1 + 4.76(2\beta - 1)} = 0 \tag{2-120}$$

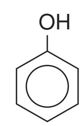
where P^* = vapor pressure at flash point temperature
P_{sys} = total system pressure, typically 1.01325×10^5 Pa
β = stoichiometric coefficient, defined by

$$\beta = N_C + N_S + \frac{N_H - N_X}{4} - \frac{N_O}{2} \tag{2-121}$$

where N_C = number of carbon atoms in compound
N_S = number of sulfur atoms in compound
N_H = number of hydrogen atoms in compound
N_X = number of halogen atoms in compound
N_O = number of oxygen atoms in compound

Procedure:
Step 1. Determine the number of carbon, sulfur, hydrogen, halogen, and oxygen atoms in the compound.
Step 2. Calculate β from Eq. (2-121).
Step 3. Substitute a temperature-dependent expression for vapor pressure in Eq. (2-120) for P^*.
Step 4. Solve Eq. (2-120) for temperature. This temperature is the flash point estimate.

Example Estimate the flash point of phenol.
Structure:



Atomic contributions:

Atom type	Number
C	6
H	6
O	1

$$\beta = 6 + \frac{6}{4} - \frac{1}{2} = 7$$

The DIPPR® 801 correlation for the vapor pressure of phenol is

$$P^* = \exp\left(95.444 - \frac{10{,}113}{T} - 10.09\ln T + 6.7603 \times 10^{-18}T^6\right)$$

When this expression is used in Eq. (2-120) and solved for temperature, one obtains T_{FP} = 348.7 K, which is 1.2 percent below the DIPRR recommended value of 353 K.

Recommended Method Flammability limits: Pintar method.
Reference: Pintar, A. J., Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.
Classification: Group contributions.
Expected uncertainty: 25 percent.

*Pintar, A. J., Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.
†Does not include contribution of atoms attached to silicon.

Applicability: Organic and inorganic compounds.
Input data: Group contributions from Tables 2-361 and 2-362.
Description: A simple GC method with first-order contributions with lower flammability limit (LFL) and upper flammability limit (UFL) in volume % given by

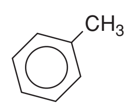
$$\mathrm{LFL} = \frac{100\%}{\sum n_i \mathrm{LFL}_i} \quad (2\text{-}122)$$

$$\mathrm{UFL} = \frac{100\%}{\sum n_i \mathrm{UFL}_i} \quad (2\text{-}123)$$

where n_i = number of groups of type i in molecule
LFL_i = contribution of group i to LFL
UFL_i = contribution of group i to UFL

Example Estimate the lower and upper flammability limits of toluene.

Structure:



Group contributions:

Group	LFL	UFL
—CH_3	17.2750	3.8461
—C_6H_5	73.8338	9.6661

Calculations using Eqs. (2-122) and (2-123):

$$\mathrm{LFL} = \frac{100\%}{17.2750 + 73.8338} = 1.10\%$$

$$\mathrm{UFL} = \frac{100\%}{3.8461 + 9.6661} = 7.40\%$$

*Pintar, A. J., *Estimation of Autoignition Temperature,* Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.
†Does not include contribution of atoms attached to silicon.

The values recommended in the DIPPR® 801 database are 1.2 and 7.1 percent, respectively.

Flammability temperatures are found by determining the temperature at which the vapor pressure equals the partial pressure corresponding to the LFL or UFL.

Recommended Methods Autoignition temperature: Pintar method.

Reference: Pintar, A. J., *Estimation of Autoignition Temperature,* Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.

Classification: Group contributions.

Expected uncertainty: 25 percent.

Applicability: Organic and inorganic compounds.

Input data: Group contributions from Tables 2-363 and 2-364.

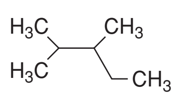
Description: A simple GC method with first-order contributions is given by

$$\text{AIT} = \sum n_i b_i \tag{2-124}$$

where n_i is the number of groups of type i in the molecule and b_i is the contribution of group i to the autoignition temperature. A more accurate but somewhat more complicated logarithmic GC method was also developed by Pintar in the same reference cited here.

Example Estimate the autoignition temperature of 2,3-dimethylpentane.

Structure and group information:



Group	n_i	b_i
—CH_3	4	301.91
>CH_2	1	−10.86
>CH—	2	−275.17

Calculation using Eq. (2-124):

$$\text{AIT} = 4(301.91) - 10.86 + 2(-275.17) = 646.4 \text{ K}$$

The estimated value is 6.3 percent above the DIPPR® 801 recommended value of 608.15 K.

MATHEMATICS

GENERAL

The basic problems of the sciences and engineering fall broadly into three categories:

1. *Steady state problems.* In such problems the configuration of the system is to be determined. This solution does not change with time but continues indefinitely in the same pattern, hence the name "steady state." Typical chemical engineering examples include steady temperature distributions in heat conduction, equilibrium in chemical reactions, and steady diffusion problems.

2. *Eigenvalue problems.* These are extensions of equilibrium problems in which critical values of certain parameters are to be determined in addition to the corresponding steady-state configurations. The determination of eigenvalues may also arise in propagation problems and stability problems. Typical chemical engineering problems include those in heat transfer and resonance in which certain boundary conditions are prescribed.

3. *Propagation problems.* These problems are concerned with predicting the subsequent behavior of a system from a knowledge of the initial state. For this reason they are often called the transient (time-varying) or unsteady-state phenomena. Chemical engineering examples include the transient state of chemical reactions (kinetics), the propagation of pressure waves in a fluid, transient behavior of an adsorption column, and the rate of approach to equilibrium of a packed distillation column.

The mathematical treatment of engineering problems involves four basic steps:

1. *Formulation.* The expression of the problem in mathematical language. That translation is based on the appropriate physical laws governing the process.

2. *Solution.* Appropriate mathematical and numerical operations are accomplished so that logical deductions may be drawn from the mathematical model.

3. *Interpretation.* Development of relations between the mathematical results and their meaning in the physical world.

4. *Refinement.* The recycling of the procedure to obtain better predictions as indicated by experimental checks.

Steps 1 and 2 are of primary interest here. The actual details are left to the various subsections, and only general approaches will be discussed.

The formulation step may result in algebraic equations, difference equations, differential equations, integral equations, or combinations of these. In any event these mathematical models usually arise from statements of physical laws such as the laws of mass and energy conservation in the form

$$\text{Input of } x - \text{output of } x + \text{production of } x = \text{accumulation of } x$$

or

$$\text{Rate of input of } x - \text{rate of output of } x + \text{rate of production of } x = \text{rate of accumulation of } x$$

where x = mass, energy, etc. These statements may be abbreviated by the statement

$$\text{Input} - \text{output} + \text{production} = \text{accumulation}$$

Many general laws of the physical universe are expressible by differential equations. Specific phenomena are then singled out from the infinity of solutions of these equations by assigning the individual initial or boundary conditions which characterize the given problem. For steady state or boundary-value problems (Fig. 3-1) the solution must

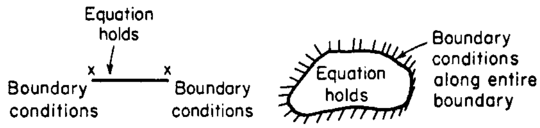

FIG. 3-1 Boundary conditions.

satisfy the differential equation inside the region and the prescribed conditions on the boundary.

In mathematical language, the propagation problem is known as an initial-value problem (Fig. 3-2). Schematically, the problem is characterized by a differential equation plus an open region in which the equation holds. The solution of the differential equation must satisfy the initial conditions plus any "side" boundary conditions.

The description of phenomena in a "continuous" medium such as a gas or a fluid often leads to partial differential equations. In particular, phenomena of "wave" propagation are described by a class of partial differential equations called "hyperbolic," and these are essentially different in their properties from other classes such as those that describe equilibrium ("elliptic") or diffusion and heat transfer ("parabolic"). Prototypes are:

1. *Elliptic.* Laplace's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

Poisson's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = g(x,y)$$

These do not contain the variable t (time) explicitly; accordingly, their solutions represent equilibrium configurations. Laplace's equation corresponds to a "natural" equilibrium, while Poisson's equation corresponds to an equilibrium under the influence of $g(x, y)$. Steady heat-transfer and mass-transfer problems are elliptic.

2. *Parabolic.* The heat equation

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}$$

describes unsteady or propagation states of diffusion as well as heat transfer.

3. *Hyperbolic.* The wave equation

$$\frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}$$

describes wave propagation of all types when the assumption is made that the wave amplitude is small and that interactions are linear.

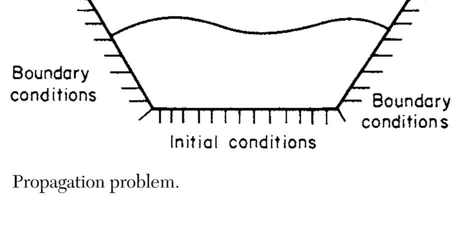

FIG. 3-2 Propagation problem.

The solution phase has been characterized in the past by a concentration on methods to obtain analytic solutions to the mathematical equations. These efforts have been most fruitful in the area of the linear equations such as those just given. However, many natural phenomena are nonlinear. While there are a few nonlinear problems that can be solved analytically, most cannot. In those cases, numerical methods are used. Due to the widespread availability of software for computers, the engineer has quite good tools available.

Numerical methods almost never fail to provide an answer to any particular situation, but they can never furnish a general solution of any problem.

The mathematical details outlined here include both analytic and numerical techniques useful in obtaining solutions to problems.

Our discussion to this point has been confined to those areas in which the governing laws are well known. However, in many areas, information on the governing laws is lacking and statistical methods are reused. Broadly speaking, statistical methods may be of use whenever conclusions are to be drawn or decisions made on the basis of experimental evidence. Since statistics could be defined as the technology of the scientific method, it is primarily concerned with the first two aspects of the method, namely, the performance of experiments and the drawing of conclusions from experiments. Traditionally the field is divided into two areas:

1. *Design of experiments.* When conclusions are to be drawn or decisions made on the basis of experimental evidence, statistical techniques are most useful when experimental data are subject to errors. The design of experiments may then often be carried out in such a fashion as to avoid some of the sources of experimental error and make the necessary allowances for that portion which is unavoidable. Second, the results can be presented in terms of probability statements which express the reliability of the results. Third, a statistical approach frequently forces a more thorough evaluation of the experimental aims and leads to a more definitive experiment than would otherwise have been performed.

2. *Statistical inference.* The broad problem of statistical inference is to provide measures of the uncertainty of conclusions drawn from experimental data. This area uses the theory of probability, enabling scientists to assess the reliability of their conclusions in terms of probability statements.

Both of these areas, the mathematical and the statistical, are intimately intertwined when applied to any given situation. The methods of one are often combined with the other. And both in order to be successfully used must result in the numerical answer to a problem—that is, they constitute the means to an end. Increasingly the numerical answer is being obtained from the mathematics with the aid of computers. The mathematical notation is given in Table 3-1.

MISCELLANEOUS MATHEMATICAL CONSTANTS

Numerical values of the constants that follow are approximate to the number of significant digits given.

$\pi = 3.1415926536$	Pi
$e = 2.7182818285$	Napierian (natural) logarithm base
$\gamma = 0.5772156649$	Euler's constant
$\ln \pi = 1.1447298858$	Napierian (natural) logarithm of pi, base e
$\log \pi = 0.4971498727$	Briggsian (common logarithm of pi, base 10
Radian = 57.2957795131°	
Degree = 0.0174532925 rad	
Minute = 0.0002908882 rad	
Second = 0.0000048481 rad	

$$\gamma = \lim_{n\to\infty}\left(\sum_{m=1}^{n}\frac{1}{m} - \ln n\right) = 0.577215$$

THE REAL-NUMBER SYSTEM

The natural numbers, or counting numbers, are the positive integers: 1, 2, 3, 4, 5, ... The negative integers are −1, −2, −3, ...

A number in the form a/b, where a and b are integers, $b \neq 0$, is a rational number. A real number that cannot be written as the quotient of two integers is called an irrational number, e.g., $\sqrt{2}$, $\sqrt{3}$, $\sqrt{5}$, π, e, $\sqrt[3]{2}$.

TABLE 3-1 Mathematical Signs, Symbols, and Abbreviations

Symbol	Meaning
$\pm\ (\mp)$	plus or minus (minus or plus)
$:$	divided by, ratio sign
$::$	proportional sign
$<$	less than
$\nless$	not less than
$>$	greater than
$\ngtr$	not greater than
$\cong$	approximately equals, congruent
$\sim$	similar to
$\asymp$	equivalent to
$\neq$	not equal to
$\doteq$	approaches, is approximately equal to
$\propto$	varies as
∞	infinity
$\therefore$	therefore
$\sqrt{\ }$	square root
$\sqrt[3]{\ }$	cube root
$\sqrt[n]{\ }$	*n*th root
$\angle$	angle
$\perp$	perpendicular to
$\parallel$	parallel to
$\lvert x\rvert$	numerical value of x
log or $\log_{10}$	common logarithm or Briggsian logarithm
$\log_e$ or ln	natural logarithm or hyperbolic logarithm or Naperian logarithm
e	base (2.718) of natural system of logarithms
a°	an angle a degrees
a' a	prime, an angle a minutes
a'' a	double prime, an angle a seconds, a second
sin	sine
cos	cosine
tan	tangent
ctn or cot	cotangent
sec	secant
csc	cosecant
vers	versed sine
covers	coversed sine
exsec	exsecant
$\sin^{-1}$	anti sine or angle whose sine is
sinh	hyperbolic sine
cosh	hyperbolic cosine
tanh	hyperbolic tangent
$\sinh^{-1}$	anti hyperbolic sine or angle whose hyperbolic sine is
$f(x)$ or $\phi(x)$	function of x
Δx	increment of x
$\sum$	summation of
dx	differential of x
dy/dx or y'	derivative of y with respect to x
d^2y/dx^2 or y''	second derivative of y with respect to x
d^ny/dx^n	nth derivative of y with respect to x
$\partial y/\partial x$	partial derivative of y with respect to x
$\partial^n y/\partial x^n$	nth partial derivative of y with respect to x
$\dfrac{\partial^n z}{\partial x \partial y}$	nth partial derivative with respect to x and y
$\int$	integral of
$\int_a^b$	integral between the limits a and b
$\dot{y}$	first derivative of y with respect to time
$\ddot{y}$	second derivative of y with respect to time
Δ or ∇^2	the "Laplacian" $\left(\dfrac{\partial^2}{\partial x^2} + \dfrac{\partial^2}{\partial y^2} + \dfrac{\partial^2}{\partial z^2}\right)$
δ	sign of a variation
$\oint$	sign for integration around a closed path

There is a one-to-one correspondence between the set of real numbers and the set of points on an infinite line (coordinate line).

Order among Real Numbers; Inequalities

$a > b$ means that $a - b$ is a positive real number.
If $a < b$ and $b < c$, then $a < c$.
If $a < b$, then $a \pm c < b \pm c$ for any real number c.
If $a < b$ and $c > 0$, then $ac < bc$.
If $a < b$ and $c < 0$, then $ac > bc$.
If $a < b$ and $c < d$, then $a + c < b + d$.
If $0 < a < b$ and $0 < c < d$, then $ac < bd$.
If $a < b$ and $ab > 0$, then $1/a > 1/b$.
If $a < b$ and $ab < 0$, then $1/a < 1/b$.

Absolute Value For any real number x, $|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x < 0 \end{cases}$

Properties
If $|x| = a$, where $a > 0$, then $x = a$ or $x = -a$.
$|x| = |-x|$; $-|x| \leq x \leq |x|$; $|xy| = |x|\,|y|$.
If $|x| < c$, then $-c < x < c$, where $c > 0$.
$||x| - |y|| \leq |x + y| \leq |x| + |y|$.
$\sqrt{x^2} = |x|$.

Proportions If $\dfrac{a}{b} = \dfrac{c}{d}$, then $\dfrac{a+b}{b} = \dfrac{c+d}{d}$, $\dfrac{a-b}{b} = \dfrac{c-d}{d}$, $\dfrac{a-b}{a+b} = \dfrac{c-d}{c+d}$.

Indeterminants

Form	Example	
$(\infty)(0)$	xe^{-x}	$x \to \infty$
0^0	x^x	$x \to 0^+$
∞^0	$(\tan x)^{\cos x}$	$x \to \frac{1}{2}\pi^-$
1^∞	$(1+x)^{1/x}$	$x \to 0^+$
$\infty - \infty$	$\sqrt{x+1} - \sqrt{x-1}$	$x \to \infty$
$\frac{0}{0}$	$\frac{\sin x}{x}$	$x \to 0$
$\frac{\infty}{\infty}$	$\frac{e^x}{x}$	$x \to \infty$

Integral Exponents (Powers and Roots) If m and n are positive integers and a, b are numbers or functions, then the following properties hold:

$$a^{-n} = 1/a^n \qquad a \neq 0$$
$$(ab)^n = a^n b^n$$
$$(a^n)^m = a^{nm}, \qquad a^n a^m = a^{n+m}$$
$$\sqrt[n]{a} = a^{1/n} \quad \text{if} \quad a > 0$$
$$\sqrt[m]{\sqrt[n]{a}} = \sqrt[mn]{a},\ a > 0$$
$$a^{m/n} = (a^m)^{1/n} = \sqrt[n]{a^m},\ a > 0$$
$$a^0 = 1\ (a \neq 0)$$
$$0^a = 0\ (a \neq 0)$$

Logarithms $\log ab = \log a + \log b,\ a > 0,\ b > 0$
$$\log a^n = n \log a$$
$$\log (a/b) = \log a - \log b$$
$$\log \sqrt[n]{a} = (1/n) \log a$$

The common logarithm (base 10) is denoted $\log a$ or $\log_{10} a$. The natural logarithm (base e) is denoted $\ln a$ (or in some texts $\log_e a$). If the text is ambiguous (perhaps using $\log x$ for $\ln x$), test the formula by evaluating it.

Roots If a is a real number, n is a positive integer, then x is called the nth root of a if $x^n = a$. The number of nth roots is n, but not all of them are necessarily real. The principal nth root means the following: (1) if $a > 0$ the principal nth root is the unique positive root, (2) if $a < 0$, and n odd, it is the unique negative root, and (3) if $a < 0$ and n even, it is any of the complex roots. In cases (1) and (2), the root can be found on a calculator by taking $y = \ln a/n$ and then $x = e^y$. In case (3), see the section on complex variables.

ALGEBRAIC INEQUALITIES

Arithmetic-Geometric Inequality Let A_n and G_n denote respectively the arithmetic and the geometric means of a set of positive numbers $a_1, a_2, \ldots, a_n$. The $A_n \geq G_n$, i.e.,

$$\frac{a_1 + a_2 + \cdots + a_n}{n} \geq (a_1 a_2 \cdots a_n)^{1/n}$$

The equality holds only if all of the numbers a_i are equal.

Carleman's Inequality The arithmetic and geometric means just defined satisfy the inequality

$$\sum_{r=1}^{n} (a_1 a_2 \cdots a_r)^{1/r} \leq neA_n$$

where e is the best possible constant in this inequality.

Cauchy-Schwarz Inequality Let $a = (a_1, a_2, \ldots, a_n)$, $b = (b_1, b_2, \ldots, b_n)$, where the a_i's and b_i's are real or complex numbers. Then

$$\left| \sum_{k=1}^{n} a_k \bar{b}_k \right|^2 \leq \left(\sum_{k=1}^{n} |a_k|^2 \right) \left(\sum_{k=1}^{n} |b_k|^2 \right)$$

The equality holds if, and only if, the vectors a, b are linearly dependent (i.e., one vector is scalar times the other vector).

Minkowski's Inequality Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be any two sets of complex numbers. Then for any real number $p > 1$,

$$\left(\sum_{k=1}^{n} |a_k + b_k|^p \right)^{1/p} \leq \left(\sum_{k=1}^{n} |a_k|^p \right)^{1/p} + \left(\sum_{k=1}^{n} |b_k|^p \right)^{1/p}$$

Hölder's Inequality Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be any two sets of complex numbers, and let p and q be positive numbers with $1/p + 1/q = 1$. Then

$$\left| \sum_{k=1}^{n} a_k \bar{b}_k \right| \leq \left(\sum_{k=1}^{n} |a_k|^p \right)^{1/p} \left(\sum_{k=1}^{n} |b_k|^q \right)^{1/q}$$

The equality holds if, and only if, the sequences $|a_1|^p, |a_2|^p, \ldots, |a_n|^p$ and $|b_1|^q, |b_2|^q, \ldots, |b_n|^q$ are proportional and the argument (angle) of the complex numbers $a_k \bar{b}_k$ is independent of k. This last condition is of course automatically satisfied if $a_1, \ldots, a_n$ and $b_1, \ldots, b_n$ are positive numbers.

Lagrange's Inequality Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be real numbers. Then

$$\left(\sum_{k=1}^{n} a_k b_k \right)^2 = \left(\sum_{k=1}^{n} a_k^2 \right) \left(\sum_{k=1}^{n} b_k^2 \right) - \sum_{1 \leq k \leq j \leq n} (a_k b_j - a_j b_k)^2$$

Example Two chemical engineers, John and Mary, purchase stock in the same company at times $t_1, t_2, \ldots, t_n$, when the price per share is respectively $p_1, p_2, \ldots, p_n$. Their methods of investment are different, however: John purchases x shares each time, whereas Mary invests P dollars each time (fractional shares can be purchased). Who is doing better?

While one can argue intuitively that the average cost per share for Mary does not exceed that for John, we illustrate a mathematical proof using inequalities. The average cost per share for John is equal to

$$\frac{\text{Total money invested}}{\text{Number of shares purchased}} = \frac{x \sum_{i=1}^{n} p_i}{nx} = \frac{1}{n} \sum_{i=1}^{n} p_i$$

The average cost per share for Mary is

$$\frac{nP}{\sum_{i=1}^{n} \frac{P}{p_i}} = \frac{n}{\sum_{i=1}^{n} \frac{1}{p_i}}$$

Thus the average cost per share for John is the arithmetic mean of $p_1, p_2, \ldots, p_n$, whereas that for Mary is the harmonic mean of these n numbers. Since the harmonic mean is less than or equal to the arithmetic mean for any set of positive numbers and the two means are equal only if $p_1 = p_2 = \cdots = p_n$, we conclude that the average cost per share for Mary is less than that for John if two of the prices p_i are distinct. One can also give a proof based on the Cauchy-Schwarz inequality. To this end, define the vectors

$$a = (p_1^{-1/2}, p_2^{-1/2}, \ldots, p_n^{-1/2}) \qquad b = (p_1^{1/2}, p_2^{1/2}, \ldots, p_n^{1/2})$$

Then $a \cdot b = 1 + \cdots + 1 = n$, and so by the Cauchy-Schwarz inequality

$$(a \cdot b)^2 = n^2 \leq \sum_{i=1}^{n} \frac{1}{p_i} \sum_{i=1}^{n} p_i$$

with the equality holding only if $p_1 = p_2 = \cdots = p_n$. Therefore

$$\frac{n}{\sum_{i=1}^{n} \frac{1}{p_i}} \leq \frac{\sum_{i=1}^{n} p_i}{n}$$

MENSURATION FORMULAS

REFERENCES: Liu, J., *Mathematical Handbook of Formulas and Tables,* McGraw-Hill, New York (1999); http://mathworld.wolfram.com/SphericalSector.html, etc.

Let A denote areas and V volumes in the following.

PLANE GEOMETRIC FIGURES WITH STRAIGHT BOUNDARIES

Triangles (see also "Plane Trigonometry") $A = \frac{1}{2}bh$ where b = base, h = altitude.

Rectangle $A = ab$ where a and b are the lengths of the sides.

Parallelogram (opposite sides parallel) $A = ah = ab \sin \alpha$ where a, b are the lengths of the sides, h the height, and α the angle between the sides. See Fig. 3-3.

Rhombus (equilateral parallelogram) $A = \frac{1}{2}ab$ where a, b are the lengths of the diagonals.

Trapezoid (four sides, two parallel) $A = \frac{1}{2}(a + b)h$ where the lengths of the parallel sides are a and b, and h = height.

Quadrilateral (four-sided) $A = \frac{1}{2}ab \sin \theta$ where a, b are the lengths of the diagonals and the acute angle between them is θ.

Regular Polygon of *n* Sides See Fig. 3-4.

$$A = \frac{1}{4} nl^2 \cot \frac{180°}{n} \qquad \text{where } l = \text{length of each side}$$

$$R = \frac{l}{2} \csc \frac{180°}{n} \qquad \text{where } R \text{ is the radius of the circumscribed circle}$$

$$r = \frac{l}{2} \cot \frac{180°}{n} \qquad \text{where } r \text{ is the radius of the inscribed circle}$$

***Radius* r *of Circle Inscribed in Triangle with Sides* a, b, c**

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}} \qquad \text{where } s = \tfrac{1}{2}(a+b+c)$$

Radius* R *of Circumscribed Circle

$$R = \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}$$

***Area of Regular Polygon of* n *Sides Inscribed in a Circle of Radius* r**

$$A = (nr^2/2) \sin (360°/n)$$

Perimeter of Inscribed Regular Polygon

$$P = 2nr \sin (180°/n)$$

***Area of Regular Polygon Circumscribed about a Circle of Radius* r**

$$A = nr^2 \tan (180°/n)$$

Perimeter of Circumscribed Regular Polygon

$$P = 2nr \tan \frac{180°}{n}$$

PLANE GEOMETRIC FIGURES WITH CURVED BOUNDARIES

Circle (Fig. 3-5) Let

C = circumference
r = radius
D = diameter
A = area
S = arc length subtended by θ
l = chord length subtended by θ
H = maximum rise of arc above chord, $r - H = d$
θ = central angle (rad) subtended by arc S

$C = 2\pi r = \pi D \qquad (\pi = 3.14159\ldots)$

$S = r\theta = \frac{1}{2}D\theta$

$l = 2\sqrt{r^2 - d^2} = 2r \sin (\theta/2) = 2d \tan (\theta/2)$

$$d = \frac{1}{2}\sqrt{4r^2 - l^2} = \frac{1}{2} l \cot \frac{\theta}{2}$$

$$\theta = \frac{S}{r} = 2 \cos^{-1} \frac{d}{r} = 2 \sin^{-1} \frac{l}{D}$$

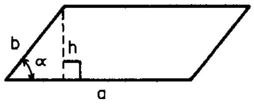

FIG. 3-3 Parallelogram.

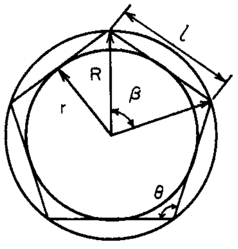

FIG. 3-4 Regular polygon.

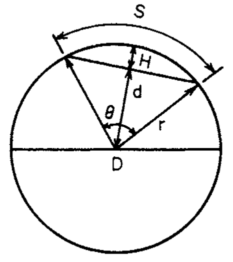

FIG. 3-5 Circle.

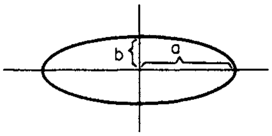

FIG. 3-6 Ellipse.

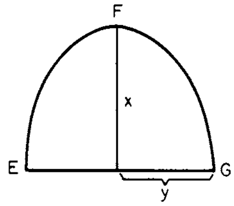

FIG. 3-7 Parabola.

$$A \text{ (circle)} = \pi r^2 = \tfrac{1}{4}\pi D^2$$

$$A \text{ (sector)} = \tfrac{1}{2} rS = \tfrac{1}{2} r^2\theta$$

$$A \text{ (segment)} = A \text{ (sector)} - A \text{ (triangle)} = \tfrac{1}{2} r^2(\theta - \sin\theta)$$

Ring (area between two circles of radii r_1 and r_2) The circles need not be concentric, but one of the circles must enclose the other.

$$A = \pi(r_1 + r_2)(r_1 - r_2) \qquad r_1 > r_2$$

Ellipse (Fig. 3-6) Let the semiaxes of the ellipse be a and b

$$A = \pi ab$$

$$C = 4aE(e)$$

where $e^2 = 1 - b^2/a^2$ and $E(e)$ is the complete elliptic integral of the second kind,

$$E(e) = \frac{\pi}{2}\left[1 - \left(\frac{1}{2}\right)^2 e^2 + \cdots\right]$$

[an approximation for the circumference $C = 2\pi\sqrt{(a^2 + b^2)/2}$].

Parabola (Fig. 3-7)

$$\text{Length of arc } EFG = \sqrt{4x^2 + y^2} + \frac{y^2}{2x} \ln \frac{2x + \sqrt{4x^2 + y^2}}{y}$$

$$\text{Area of section } EFG = \frac{4}{3} xy$$

Catenary (the curve formed by a cord of uniform weight suspended freely between two points A, B; Fig. 3-8)

$$y = a \cosh (x/a)$$

Length of arc between points A and B is equal to $2a \sinh (L/a)$. Sag of the cord is $D = a \cosh (L/a) - a$.

SOLID GEOMETRIC FIGURES WITH PLANE BOUNDARIES

Cube Volume $= a^3$; total surface area $= 6a^2$; diagonal $= a\sqrt{3}$, where a = length of one side of the cube.

Rectangular Parallelepiped Volume $= abc$; surface area $= 2(ab + ac + bc)$; diagonal $= \sqrt{a^2 + b^2 + c^2}$, where a, b, c are the lengths of the sides.

Prism Volume = (area of base) × (altitude); lateral surface area = (perimeter of right section) × (lateral edge).

Pyramid Volume = ⅓ (area of base) × (altitude); lateral area of regular pyramid = ½ (perimeter of base) × (slant height) = ½ (number of sides) (length of one side) (slant height).

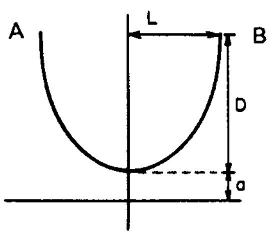

FIG. 3-8 Catenary.

Frustum of Pyramid (formed from the pyramid by cutting off the top with a plane

$$V = \tfrac{1}{3}(A_1 + A_2 + \sqrt{A_1 \cdot A_2})h$$

where h = altitude and A_1, A_2 are the areas of the base; lateral area of a regular figure = ½ (sum of the perimeters of base) × (slant height).

Volume and Surface Area of Regular Polyhedra with Edge *l*

Type of surface	Name	Volume	Surface area
4 equilateral triangles	Tetrahedron	$0.1179\, l^3$	$1.7321\, l^2$
6 squares	Hexahedron (cube)	$1.0000\, l^3$	$6.0000\, l^2$
8 equilateral triangles	Octahedron	$0.4714\, l^3$	$3.4641\, l^2$
12 pentagons	Dodecahedron	$7.6631\, l^3$	$20.6458\, l^2$
20 equilateral triangles	Icosahedron	$2.1817\, l^3$	$8.6603\, l^2$

SOLIDS BOUNDED BY CURVED SURFACES

Cylinders (Fig. 3-9) V = (area of base) × (altitude); lateral surface area = (perimeter of right section) × (lateral edge).

Right Circular Cylinder $V = \pi$ (radius)^2 × (altitude); lateral surface area = 2π (radius) × (altitude).

Truncated Right Circular Cylinder

$$V = \pi r^2 h; \text{ lateral area} = 2\pi rh$$

$$h = \tfrac{1}{2}(h_1 + h_2)$$

Hollow Cylinders Volume $= \pi h(R^2 - r^2)$, where r and R are the internal and external radii and h is the height of the cylinder.

Sphere (Fig. 3-10)

$$V \text{ (sphere)} = \tfrac{4}{3}\pi R^3, \ \tfrac{1}{6}\pi D^3$$

V (spherical sector) $= \tfrac{2}{3}\pi R^2 h_i$ = 2 (open spherical sector), i = 1 (spherical cone)

$$V \text{ (spherical segment of one base)} = \tfrac{1}{6}\pi h_1(3r_2^2 + h_1^2)$$

$$V \text{ (spherical segment of two bases)} = \tfrac{1}{6}\pi h_2(3r_1^2 + 3r_2^2 + h_2^2)$$

$$A \text{ (sphere)} = 4\pi R^2 = \pi D^2$$

$$A \text{ (zone)} = 2\pi Rh = \pi Dh$$

A (lune on the surface included between two great circles, the inclination of which is θ radians) $= 2R^2\theta$.

Cone V = ⅓ (area of base) × (altitude).

Right Circular Cone $V = (\pi/3)\, r^2 h$, where h is the altitude and r is the radius of the base; curved surface area $= \pi r\sqrt{r^2 + h^2}$, curved surface of the frustum of a right cone $= \pi(r_1 + r_2)\sqrt{h^2 + (r_1 - r_2)^2}$, where r_1, r_2 are the radii of the base and top, respectively, and h is the altitude; volume of the frustum of a right cone $= \pi(h/3)(r_1^2 + r_1 r_2 + r_2^2) = h/3(A_1 + A_2 + \sqrt{A_1 A_2})$, where A_1 = area of base and A_2 = area of top.

Ellipsoid $V = (\tfrac{4}{3})\pi abc$, where a, b, c are the lengths of the semiaxes.

Torus (obtained by rotating a circle of radius r about a line whose distance is $R > r$ from the center of the circle)

$$V = 2\pi^2 Rr^2 \qquad \text{Surface area} = 4\pi^2 Rr$$

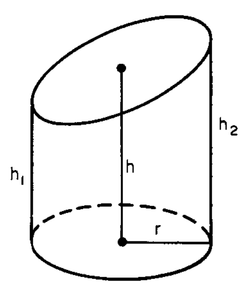

FIG. 3-9 Cylinder.

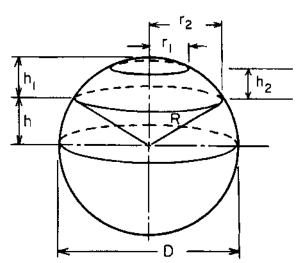

FIG. 3-10 Sphere.

Prolate Spheroid (formed by rotating an ellipse about its major axis [2a])

$$\text{Surface area} = 2\pi b^2 + 2\pi(ab/e)\sin^{-1} e \qquad V = \tfrac{4}{3}\pi ab^2$$

where a, b are the major and minor axes and e = eccentricity ($e < 1$).

Oblate Spheroid (formed by the rotation of an ellipse about its minor axis [2b]) Data as given previously.

$$\text{Surface area} = 2\pi a^2 + \pi \frac{b^2}{e} \ln \frac{1+e}{1-e} \qquad V = \tfrac{4}{3}\pi a^2 b$$

For process vessels, the formulas reduce to the following:

Hemisphere

$$V = \frac{\pi}{12} D^3, \quad A = \frac{\pi}{2} D^2$$

For a hemisphere (concave up) partially filled to a depth h_1, use the formulas for spherical segment with one base, which simplify to

$$V = \pi h_1^2(R - h_1/3) = \pi h_1^2(D/2 - h_1/3)$$
$$A = 2\pi R h_1 = \pi D h_1$$

For a hemisphere (concave down) partially filled from the bottom, use the formulas for a spherical segment of two bases, one of which is a plane through the center, where h = distance from the center plane to the surface of the partially filled hemisphere.

$$V = \pi h(R^2 - h^2/3) = \pi h(D^2/4 - h^2/3)$$
$$A = 2\pi R h = \pi D h$$

Cone For a cone partially filled, use the same formulas as for right circular cones, but use r and h for the region filled.

Ellipsoid If the base of a vessel is one-half of an oblate spheroid (the cross section fitting to a cylinder is a circle with radius of $D/2$ and the minor axis is smaller), then use the formulas for one-half of an oblate spheroid.

$$V = 0.1745D^3,\ S = 1.236D^2,\ \text{minor axis} = D/3$$
$$V = 0.1309D^3,\ S = 1.084D^2,\ \text{minor axis} = D/4$$

MISCELLANEOUS FORMULAS

See also "Differential and Integral Calculus."

Volume of a Solid Revolution (the solid generated by rotating a plane area about the x axis)

$$V = \pi \int_a^b [f(x)]^2\, dx$$

where $y = f(x)$ is the equation of the plane curve and $a \le x \le b$.

Area of a Surface of Revolution

$$S = 2\pi \int_a^b y\, ds$$

where $ds = \sqrt{1 + (dy/dx)^2}\, dx$ and $y = f(x)$ is the equation of the plane curve rotated about the x axis to generate the surface.

Area Bounded by $f(x)$, the x Axis, and the Lines $x = a$, $x = b$

$$A = \int_a^b f(x)\, dx \qquad [f(x) \ge 0]$$

Length of Arc of a Plane Curve

If $y = f(x)$,

$$\text{Length of arc } s = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx$$

If $x = g(y)$,

$$\text{Length of arc } s = \int_c^d \sqrt{1 + \left(\frac{dx}{dy}\right)^2}\, dy$$

If $x = f(t)$, $y = g(t)$,

$$\text{Length of arc } s = \int_{t_0}^{t_1} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt$$

In general, $(ds)^2 = (dx)^2 + (dy)^2$.

IRREGULAR AREAS AND VOLUMES

Irregular Areas Let $y_0, y_1, \ldots, y_n$ be the lengths of a series of equally spaced parallel chords and h be their distance apart (Fig. 3-11). The area of the figure is given approximately by any of the following:

$$A_T = (h/2)[(y_0 + y_n) + 2(y_1 + y_2 + \cdots + y_{n-1})] \qquad \text{(trapezoidal rule)}$$

$$A_s = (h/3)[(y_0 + y_n) + 4(y_1 + y_3 + y_5 + \cdots + y_{n-1}) + 2(y_2 + y_4 + \cdots + y_{n-2})] \quad (n \text{ even, Simpson's rule})$$

The greater the value of n, the greater the accuracy of approximation.

Irregular Volumes To find the volume, replace the y's by cross-sectional areas A_j and use the results in the preceding equations.

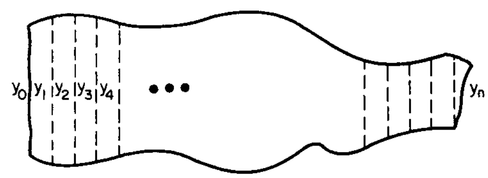

FIG. 3-11 Irregular area.

ELEMENTARY ALGEBRA

OPERATIONS ON ALGEBRAIC EXPRESSIONS

An algebraic expression will here be denoted as a combination of letters and numbers such as

$$3ax - 3xy + 7x^2 + 7x^{3/2} - 2.8xy$$

Addition and Subtraction Only like terms can be added or subtracted in two algebraic expressions.

Example $(3x + 4xy - x^2) + (3x^2 + 2x - 8xy) = 5x - 4xy + 2x^2$.

Example $(2^x + 3xy - 4x^{1/2}) + (3^x + 6x - 8xy) = 2^x + 3^x + 6x - 5xy - 4x^{1/2}$.

Multiplication Multiplication of algebraic expressions is term by term, and corresponding terms are combined.

Example $(2x + 3y - 2xy)(3 + 3y) = 6x + 9y + 9y^2 - 6xy^2$.

Division This operation is analogous to that in arithmetic.

Example Divide $3e^{2x} + e^x + 1$ by $e^x + 1$.

$$\begin{array}{l} \text{Dividend} \\ \text{Divisor } \underline{e^x+1} \mid 3e^{2x}+e^x+1 \ \underline{3e^x-2} \text{ quotient} \\ \quad \underline{3e^{2x}+3e^x} \\ \quad -2e^x+1 \\ \quad \underline{-2e^x-2} \\ \quad\quad +3 \text{ (remainder)} \end{array}$$

Therefore, $3e^{2x} + e^x + 1 = (e^x + 1)(3e^x - 2) + 3$.

Operations with Zero All numerical computations (except division) can be done with zero: $a + 0 = 0 + a = a$; $a - 0 = a$; $0 - a = -a$; $(a)(0) = 0$; $a^0 = 1$ if $a \neq 0$; $0/a = 0$, $a \neq 0$. $a/0$ and $0/0$ have no meaning.

Fractional Operations

$$-\frac{x}{y} = -\left(\frac{-x}{-y}\right) = \frac{x}{-y} = \frac{-x}{y}; \quad \frac{x}{y} = \frac{-x}{-y}; \quad \frac{x}{y} = \frac{ax}{ay}, \text{ if } a \neq 0.$$

$$\frac{x}{y} \pm \frac{z}{y} = \frac{x \pm z}{y}; \quad \left(\frac{x}{y}\right)\left(\frac{z}{t}\right) = \frac{xz}{yt}; \quad \frac{x/y}{z/t} = \left(\frac{x}{y}\right)\left(\frac{t}{z}\right) = \frac{xt}{yz}$$

Factoring That process of analysis consisting of reducing a given expression into the product of two or more simpler expressions called *factors.* Some of the more common expressions are factored here:

(1) $(x^2 - y^2) = (x - y)(x + y)$

(2) $x^2 + 2xy + y^2 = (x + y)^2$

(3) $x^3 - y^3 = (x - y)(x^2 + xy + y^2)$

(4) $(x^3 + y^3) = (x + y)(x^2 - xy + y^2)$

(5) $(x^4 - y^4) = (x - y)(x + y)(x^2 + y^2)$

(6) $x^5 + y^5 = (x + y)(x^4 - x^3y + x^2y^2 - xy^3 + y^4)$

(7) $x^n - y^n = (x - y)(x^{n-1} + x^{n-2}y + x^{n-3}y^2 + \cdots + y^{n-1})$

Laws of Exponents

$(a^n)^m = a^{nm}$; $a^{n+m} = a^n \cdot a^m$; $a^{n/m} = (a^n)^{1/m}$; $a^{n-m} = a^n/a^m$; $a^{1/m} = \sqrt[m]{a}$; $a^{1/2} = \sqrt{a}$; $\sqrt{x^2} = |x|$ (absolute value of x). For $x > 0$, $y > 0$, $\sqrt{xy} = \sqrt{x}\sqrt{y}$; for $x > 0$ $\sqrt[n]{x^m} = x^{m/n}$; $\sqrt[n]{1/x} = 1/\sqrt[n]{x}$

THE BINOMIAL THEOREM

If n is a positive integer,

$$(a + b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{2!}a^{n-2}b^2 + \frac{n(n-1)(n-2)}{3!}a^{n-3}b^3 + \cdots + b^n = \sum_{j=0}^{n}\binom{n}{j}a^{n-j}b^j$$

where $\binom{n}{j} = \frac{n!}{j!(n-j)!}$ = number of combinations of n things taken j at a time. $n! = 1 \cdot 2 \cdot 3 \cdot 4 \cdots n$, $0! = 1$.

Example Find the sixth term of $(x + 2y)^{12}$. The sixth term is obtained by setting $j = 5$. It is

$$\binom{12}{5}x^{12-5}(2y)^5 = 792x^7(2y)^5$$

Example $\sum_{j=0}^{14}\binom{n}{j} = (1 + 1)^{14} = 2^{14}$.

If n is not a positive integer, the sum formula no longer applies and an infinite series results for $(a + b)^n$. The coefficients are obtained from the first formulas in this case.

Example $(1 + x)^{1/2} = 1 + \frac{1}{2}x - \frac{1}{2} \cdot \frac{1}{4}x^2 + \frac{1}{2} \cdot \frac{1}{4} \cdot \frac{3}{6}x^3 \cdots$ (convergent for $x^2 < 1$).

Additional discussion is under "Infinite Series."

PROGRESSIONS

An arithmetic progression is a succession of terms such that each term, except the first, is derivable from the preceding by the addition of a quantity d called the common difference. All arithmetic progressions have the form a, $a + d$, $a + 2d$, $a + 3d$, ... With a = first term, l = last term, d = common difference, n = number of terms, and s = sum of the terms, the following relations hold:

$$l = a + (n - 1)d = \frac{s}{n} + \frac{(n-1)}{2}d$$

$$s = \frac{n}{2}[2a + (n - 1)d] = \frac{n}{2}(a + l) = \frac{n}{2}[2l - (n - 1)d]$$

$$a = l - (n - 1)d = \frac{s}{n} - \frac{(n-1)d}{2} = \frac{2s}{n} - l$$

$$d = \frac{l - a}{n - 1} = \frac{2(s - an)}{n(n-1)} = \frac{2(nl - s)}{n(n-1)}$$

$$n = \frac{l - a}{d} + 1 = \frac{2s}{l + a}$$

The **arithmetic mean or average** of two numbers a, b is $(a + b)/2$; of n numbers $a_1, \ldots, a_n$ is $(a_1 + a_2 + \cdots + a_n)/n$.

A **geometric progression** is a succession of terms such that each term, except the first, is derivable from the preceding by the multiplication of a quantity r called the common ratio. All such progressions have the form a, ar, ar^2, . . . , ar^{n-1}. With a = first term, l = last term, r = ratio, n = number of terms, s = sum of the terms, the following relations hold:

$$l = ar^{n-1} = \frac{[a + (r - 1)s]}{r} = \frac{(r-1)sr^{n-1}}{r^n - 1}$$

$$s = \frac{a(r^n - 1)}{r - 1} = \frac{a(1 - r^n)}{1 - r} = \frac{rl - a}{r - 1} = \frac{lr^n - l}{r^n - r^{n-1}}$$

$$a = \frac{l}{r^{n-l}} = \frac{(r-1)s}{r^n - 1}, \quad r = \frac{s - a}{s - l}, \quad \log r = \frac{\log l - \log a}{n - 1}$$

$$n = \frac{\log l - \log a}{\log r} + 1 = \frac{\log[a + (r-1)s] - \log a}{\log r}$$

The geometric mean of two nonnegative numbers a, b is $\sqrt{ab}$; of n numbers is $(a_1a_2 \ldots a_n)^{1/n}$. The geometric mean of a set of positive numbers is less than or equal to the arithmetic mean.

Example Find the sum of $1 + \frac{1}{2} + \frac{1}{4} + \cdots + \frac{1}{64}$. Here $a = 1$, $r = \frac{1}{2}$, $n = 7$. Thus

$$s = \frac{\frac{1}{2}(\frac{1}{64}) - 1}{\frac{1}{2} - 1} = 127/64$$

$$s = a + ar + ar^2 + \cdots + ar^{n-1} = \frac{a}{1 - r} - \frac{ar^n}{1 - r}$$

If $|r| < 1$, then $\lim_{n\to\infty} s = \frac{a}{1 - r}$

which is called the sum of the infinite geometric progression.

Example The present worth (PW) of a series of cash flows C_k at the end of year k is

$$PW = \sum_{k=1}^{n}\frac{C_k}{(1 + i)^k}$$

where i is an assumed interest rate. (Thus the present worth always requires specification of an interest rate.) If all the payments are the same, $C_k = R$, the present worth is

$$PW = R\sum_{k=1}^{n}\frac{1}{(1 + i)^k}$$

This can be rewritten as

$$PW = \frac{R}{1 + i}\sum_{k=1}^{n}\frac{1}{(1 + i)^{k-1}} = \frac{R}{1 + i}\sum_{j=0}^{n-1}\frac{1}{(1 + i)^j}$$

This is a geometric series with $r = 1/(1 + i)$ and $a = R/(1 + i)$. The formulas above give

$$\text{PW } (=s) = \frac{R}{i}\,\frac{(1+i)^n - 1}{(1+i)^n}$$

The same formula applies to the value of an annuity (PW) now, to provide for equal payments R at the end of each of n years, with interest rate i.

A progression of the form $a, (a + d)r, (a + 2d)r^2, (a + 3d)r^3$, etc., is a combined arithmetic and geometric progression. The sum of n such terms is

$$s = \frac{a - [a + (n-1)d]r^n}{1 - r} + \frac{rd(1 - r^{n-1})}{(1-r)^2}$$

If $|r| < 1$, $\lim_{n\to\infty} s = \dfrac{a}{1-r} + rd/(1 - r)^2$.

The non-zero numbers a, b, c, etc., form a harmonic progression if their reciprocals $1/a, 1/b, 1/c$, etc., form an arithmetic progression.

Example The progression 1, ⅓, ⅕, ⅐, . . . , 1/31 is harmonic since 1, 3, 5, 7, . . . , 31 form an arithmetic progression.

The **harmonic mean** of two numbers a, b is $2ab/(a + b)$.

PERMUTATIONS, COMBINATIONS, AND PROBABILITY

Each separate arrangement of all or a part of a set of things is called a **permutation.** The number of permutations of n things taken r at a time, written

$$P(n, r) = \frac{n!}{(n-r)!} = n(n-1)(n-2)\cdots(n-r+1)$$

Each separate selection of objects that is possible irrespective of the order in which they are arranged is called a combination. The number of combinations of n things taken r at a time, written $C(n, r) = n!/[r!(n - r)!]$.

An important relation is $r!\,C(n, r) = P(n, r)$.

If an event can occur in p ways and fail to occur in q ways, all ways being equally likely, the *probability* of its occurrence is $p/(p + q)$, and that of its failure $q/(p + q)$.

Example Two dice may be thrown in 36 separate ways. What is the probability of throwing such that their sum is 7? Seven may arise in 6 ways: 1 and 6, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1. The probability of shooting 7 is ⅙.

THEORY OF EQUATIONS

Linear Equations A linear equation is one of the first degree (i.e., only the first powers of the variables are involved), and the process of obtaining definite values for the unknown is called solving the equation. Every linear equation in one variable is written $Ax + B = 0$ or $x = -B/A$. Linear equations in n variables have the form

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ &\vdots \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= b_m \end{aligned}$$

The solution of the system may then be found by elimination or matrix methods if a solution exists (see "Matrix Algebra and Matrix Computations").

Quadratic Equations Every quadratic equation in one variable is expressible in the form $ax^2 + bx + c = 0$. $a \neq 0$. This equation has two solutions, say, x_1, x_2, given by

$$\left.\begin{matrix} x_1 \\ x_2 \end{matrix}\right\} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

If a, b, c are real, the discriminant $b^2 - 4ac$ gives the character of the roots. If $b^2 - 4ac > 0$, the roots are real and unequal. If $b^2 - 4ac < 0$, the roots are complex conjugates. If $b^2 - 4ac = 0$ the roots are **real** and **equal.** Two quadratic equations in two variables can in general be solved only by numerical methods (see "Numerical Analysis and Approximate Methods").

Cubic Equations A cubic equation, in one variable, has the form $x^3 + bx^2 + cx + d = 0$. Every cubic equation having complex coefficients has three complex roots. If the coefficients are real numbers, then at least one of the roots must be real. The cubic equation $x^3 + bx^2 + cx + d = 0$ may be reduced by the substitution $x = y - (b/3)$ to the form $y^3 + py + q = 0$, where $p = \frac{1}{3}(3c - b^2)$, $q = \frac{1}{27}(27d - 9bc + 2b^3)$. This equation has the solutions $y_1 = A + B$, $y_2 = -\frac{1}{2}(A + B) + (i\sqrt{3}/2)(A - B)$, $y_3 = -\frac{1}{2}(A + B) - (i\sqrt{3}/2)(A - B)$, where $i^2 = -1$, $A = \sqrt[3]{-q/2 + \sqrt{R}}$, $B = \sqrt[3]{-q/2 - \sqrt{R}}$, and $R = (p/3)^3 + (q/2)^2$. If b, c, d are all real and if $R > 0$, there are one real root and two conjugate complex roots; if $R = 0$, there are three real roots, of which at least two are equal; if $R < 0$, there are three real unequal roots. If $R < 0$, these formulas are impractical. In this case, the roots are given by $y_k = \mp 2\sqrt{-p/3}\cos[(\phi/3) + 120k]$, $k = 0, 1, 2$ where

$$\phi = \cos^{-1}\sqrt{\frac{q^2/4}{-p^3/27}}$$

and the upper sign applies if $q > 0$, the lower if $q < 0$.

Example $y^3 - 7y + 7 = 0$. $p = -7$, $q = 7$, $R < 0$. Hence

$$y_k = -\sqrt{\frac{28}{3}}\cos\left(\frac{\phi}{3} + 120k\right)$$

where $\quad \phi = \cos^{-1}\sqrt{\dfrac{27}{28}},\ \dfrac{\phi}{3} = 3.6311315 \text{ rad} = 3°37'52''$

The roots are approximately −3.048917, 1.692021, and 1.356896.

Example Many equations of state involve solving cubic equations for the compressibility factor Z. For example, the Redlich-Kwong-Soave equation of state requires solving

$$Z^3 - Z^2 + cZ + d = 0, \quad d < 0$$

where c and d depend on critical constants of the chemical species. In this case, only positive solutions, $Z > 0$, are desired.

Quartic Equations See Abramowitz and Stegun (1972, p. 17).

General Polynomials of the *n*th Degree Denote the general polynomial equation of degree n by

$$P(x) = a_0x^n + a_1x^{n-1} + \cdots + a_{n-1}x + a_n = 0$$

If $n > 4$, there is no formula which gives the roots of the general equation. For fourth and higher order (even third order), the roots can be found numerically (see "Numerical Analysis and Approximate Methods"). However, there are some general theorems that may prove useful.

Remainder Theorems When $P(x)$ is a polynomial and $P(x)$ is divided by $x - a$ until a remainder independent of x is obtained, this remainder is equal to $P(a)$.

Example $P(x) = 2x^4 - 3x^2 + 7x - 2$ when divided by $x + 1$ (here $a = -1$) results in $P(x) = (x + 1)(2x^3 - 2x^2 - x + 8) - 10$ where −10 is the remainder. It is easy to see that $P(-1) = -10$.

Factor Theorem If $P(a)$ is zero, the polynomial $P(x)$ has the factor $x - a$. In other words, if a is a root of $P(x) = 0$, then $x - a$ is a factor of $P(x)$.

If a number a is found to be a root of $P(x) = 0$, the division of $P(x)$ by $(x - a)$ leaves a polynomial of degree one less than that of the original equation, i.e., $P(x) = Q(x)(x - a)$. Roots of $Q(x) = 0$ are clearly roots of $P(x) = 0$.

Example $P(x) = x^3 - 6x^2 + 11x - 6 = 0$ has the root + 3. Then $P(x) = (x - 3)(x^2 - 3x + 2)$. The roots of $x^2 - 3x + 2 = 0$ are 1 and 2. The roots of $P(x)$ are therefore 1, 2, 3.

Fundamental Theorem of Algebra Every polynomial of degree n has exactly n real or complex roots, counting multiplicities.

Every polynomial equation $a_0x^n + a_1x^{n-1} + \cdots + a_n = 0$ with *rational coefficients* may be rewritten as a polynomial, of the same degree, with *integral coefficients* by multiplying each coefficient by the least common multiple of the denominators of the coefficients.

Example The coefficients of $\frac{3}{2}x^4 + \frac{7}{3}x^3 - \frac{5}{6}x^2 + 2x - \frac{1}{6} = 0$ are rational numbers. The least common multiple of the denominators is 2 × 3 = 6. Therefore, the equation is equivalent to $9x^4 + 14x^3 - 5x^2 + 12x - 1 = 0$.

Determinants Consider the system of two linear equations

$$a_{11}x_1 + a_{12}x_2 = b_1$$
$$a_{21}x_1 + a_{22}x_2 = b_2$$

If the first equation is multiplied by a_{22} and the second by $-a_{12}$ and the results added, we obtain

$$(a_{11}a_{22} - a_{21}a_{12})x_1 = b_1a_{22} - b_2a_{12}$$

The expression $a_{11}a_{22} - a_{21}a_{12}$ may be represented by the symbol

$$\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{21}a_{12}$$

This symbol is called a determinant of second order. The value of the square array of n^2 quantities a_{ij}, where $i = 1, \ldots, n$ is the row index, $j = 1, \ldots, n$ the column index, written in the form

$$|A| = \begin{vmatrix} a_{11} & a_{12} & a_{13} \cdots a_{1n} \\ a_{21} & a_{22} & \cdots\cdots a_{2n} \\ \vdots & & \\ a_{n1} & a_{n2} & a_{n3} \cdots a_{nn} \end{vmatrix}$$

is called a determinant. The n^2 quantities a_{ij} are called the elements of the determinant. In the determinant $|A|$ let the ith row and jth column be deleted and a new determinant be formed having $n - 1$ rows and columns. This new determinant is called the minor of a_{ij} denoted M_{ij}.

Example $\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$ The minor of a_{23} is $M_{23} = \begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix}$

The cofactor A_{ij} of the element a_{ij} is the signed minor of a_{ij} determined by the rule $A_{ij} = (-1)^{i+j}M_{ij}$. The *value* of $|A|$ is obtained by forming any of the equivalent expressions $\sum_{j=1}^{n} a_{ij}A_{ij}$, $\sum_{i=1}^{n} a_{ij}A_{ij}$, where the elements a_{ij} must be taken from a single row or a single column of A.

Example

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = a_{31}A_{31} + a_{32}A_{32} + a_{33}A_{33}$$

$$= a_{31}\begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} - a_{32}\begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} + a_{33}\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}$$

In general, A_{ij} will be determinants of order $n - 1$, but they may in turn be expanded by the rule. Also,

$$\sum_{j=1}^{n} a_{ji}A_{jk} = \sum_{j=1}^{n} a_{ij}A_{jk} = \begin{cases} |A| & i = k \\ 0 & i \neq k \end{cases}$$

Fundamental Properties of Determinants

1. The value of a determinant $|A|$ is not changed if the rows and columns are interchanged.
2. If the elements of one row (or one column) of a determinant are all zero, the value of $|A|$ is zero.
3. If the elements of one row (or column) of a determinant are multiplied by the same constant factor, the value of the determinant is multiplied by this factor.
4. If one determinant is obtained from another by interchanging any two rows (or columns), the value of either is the negative of the value of the other.
5. If two rows (or columns) of a determinant are identical, the value of the determinant is zero.
6. If two determinants are identical except for one row (or column), the sum of their values is given by a single determinant obtained by adding corresponding elements of dissimilar rows (or columns) and leaving unchanged the remaining elements.
7. The value of a determinant is not changed if one row (or column) is multiplied by a constant and added to another row (or column).

ANALYTIC GEOMETRY

Edwards, *Calculus with Analytic Geometry,* 7th ed., Houghton Mifflin (2001); Riddle, D. F., *Analytic Geometry,* 6th ed., Thompson Learning (1996); Spiegel, M. R., and J. Liu, *Mathematical Handbook of Formulas and Tables,* 2d ed., McGraw-Hill (1999); Thomas, G. B., Jr., and R. L. Finney, *Calculus and Analytic Geometry,* 9th ed., Addison-Wesley (1996).

Analytic geometry uses algebraic equations and methods to study geometric problems. It also permits one to visualize algebraic equations in terms of geometric curves, which frequently clarifies abstract concepts.

PLANE ANALYTIC GEOMETRY

Coordinate Systems The basic concept of analytic geometry is the establishment of a one-to-one correspondence between the points of the plane and number pairs (x, y). This correspondence may be done in a number of ways. The rectangular or cartesian coordinate system consists of two straight lines intersecting at right angles (Fig. 3-12). A point is designated by (x, y), where x (the abscissa) is the distance of the point from the y axis measured parallel to the x axis, positive if to the right, negative to the left. y (ordinate) is the distance of the point from the x axis, measured parallel to the y axis, positive if above, negative if below the x axis. The **quadrants** are labeled 1, 2, 3, 4 in the drawing, the coordinates of points in the various quadrants having the depicted signs. Another common coordinate system is the polar coordinate system (Fig. 3-13). In this system the position of a point is designated by the pair (r, θ), $r = \sqrt{x^2 + y^2}$ being the distance to the origin $0(0,0)$ and θ being the angle the line r makes with the positive x axis (polar axis). To change from polar to rectangular coordinates, use $x = r \cos \theta$ and $y = r \sin \theta$. To change from rectangular to polar coordinates, use $r = \sqrt{x^2 + y^2}$ and $\theta = \tan^{-1}(y/x)$ if $x \neq 0$; $\theta = \pi/2$ if $x = 0$. The distance between two points (x_1, y_1), (x_2, y_2) is defined by $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$ in rectangular coordinates or by $d = \sqrt{r_1^2 + r_2^2 - 2r_1r_2 \cos(\theta_1 - \theta_2)}$ in polar coordinates. Other coordinate systems are sometimes used. For example, on the surface of a sphere latitude and longitude prove useful.

The Straight Line (Fig. 3-14) The slope m of a straight line is the tangent of the inclination angle θ made with the positive x axis. If

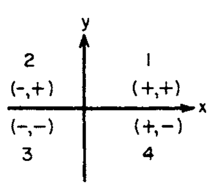

FIG. 3-12 Rectangular coordinates.

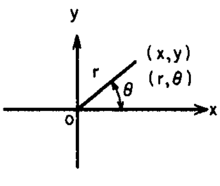

FIG. 3-13 Polar coordinates.

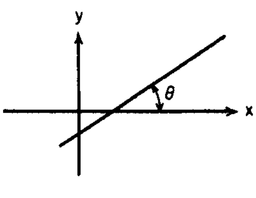

FIG. 3-14 Straight line.

(x_1, y_1) and (x_2, y_2) are any two points on the line, slope $= m = (y_2 - y_1)/(x_2 - x_1)$. The slope of a line parallel to the x axis is zero; parallel to the y axis, it is undefined. Two lines are parallel if and only if they have the same slope. Two lines are perpendicular if and only if the product of their slopes is −1 (the exception being that case when the lines are parallel to the coordinate axes). Every equation of the type $Ax + By + C = 0$ represents a straight line, and every straight line has an equation of this form. A straight line is determined by a variety of conditions:

	Given conditions	Equation of line
(1)	Parallel to x axis	$y =$ constant
(2)	Parallel y axis	$x =$ constant
(3)	Point (x_1, y_1) and slope m	$y - y_1 = m(x - x_1)$
(4)	Intercept on y axis $(0, b)$, m	$y = mx + b$
(5)	Intercept on x axis $(a, 0)$, m	$y = m(x - a)$
(6)	Two points (x_1, y_1), (x_2, y_2)	$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1)$
(7)	Two intercepts $(a, 0)$, $(0, b)$	$x/a + y/b = 1$

The angle β a line with slope m_1 makes with a line having slope m_2 is given by $\tan \beta = (m_2 - m_1)/(m_1 m_2 + 1)$. A line is determined if the length and direction of the perpendicular to it (the normal) from the origin are given (see Fig. 3-15). Let p = length of the perpendicular and α the angle that the perpendicular makes with the positive x axis. The equation of the line is $x \cos \alpha + y \sin \alpha = p$. The equation of a line perpendicular to a given line of slope m and passing through a point (x_1, y_1) is $y - y_1 = -(1/m)(x - x_1)$. The distance from a point (x_1, y_1) to a line with equation $Ax + By + C = 0$ is

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$$

Occasionally some nonlinear algebraic equations can be reduced to linear equations under suitable substitutions or changes of variables. In other words, certain curves become the graphs of lines if the scales or coordinate axes are appropriately transformed.

Example Consider $y = bx^n$. $B = \log b$. Taking logarithms $\log y = n \log x + \log b$. Let $Y = \log y$, $X = \log x$, $B = \log b$. The equation then has the form $Y = nX + B$, which is a linear equation. Consider $k = k_0 \exp(-E/RT)$, taking logarithms $\log_e k = \log_e k_0 - E/(RT)$. Let $Y = \log_e k$, $B = \log_e k_0$, and $m = -E/R$, $X = 1/T$, and the result is $Y = mX + B$. Next consider $y = a + bx^n$. If the substitution $t = x^n$ is made, then the graph of y is a straight line versus t.

Asymptotes The limiting position of the tangent to a curve as the point of contact tends to an infinite distance from the origin is called an **asymptote.** If the equation of a given curve can be expanded in a Laurent power series such that

$$f(x) = \sum_{k=0}^{n} a_k x^k + \sum_{k=1}^{n} \frac{b_k}{x^k}$$

and

$$\lim_{x\to\infty} f(x) = \sum_{k=0}^{n} a_k x^k$$

then the equation of the asymptote is $y = \sum_{k=0}^{n} a_k x^k$. If $n = 1$, then the asymptote is (in general oblique) a line. In this case, the equation of the asymptote may be written as

$$y = mx + b \qquad m = \lim_{x\to\infty} f'(x)$$

$$b = \lim_{x\to\infty} [f(x) - xf'(x)]$$

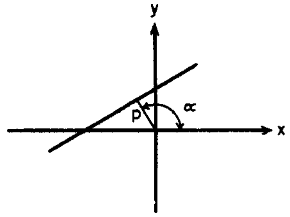

FIG. 3-15 Determination of line.

Geometric Properties of a Curve When the Equation Is Given The analysis of the properties of an equation is facilitated by the investigation of the equation by using the following techniques:

1. *Points of maximum, minimum, and inflection.* These may be investigated by means of the calculus.
2. *Symmetry.* Let $F(x, y) = 0$ be the equation of the curve.

Condition on $F(x, y)$	Symmetry
$F(x, y) = F(-x, y)$	With respect to y axis
$F(x, y) = F(x, -y)$	With respect to x axis
$F(x, y) = F(-x, -y)$	With respect to origin
$F(x, y) = F(y, x)$	With respect to the line $y = x$

3. *Extent.* Only real values of x and y are considered in obtaining the points (x, y) whose coordinates satisfy the equation. The extent of them may be limited by the condition that negative numbers do not have real square roots.
4. *Intercepts.* Find those points where the curves of the function cross the coordinate axes.
5. *Asymptotes.* See preceding discussion.
6. *Direction at a point.* This may be found from the derivative of the function at a point. This concept is useful for distinguishing among a family of similar curves.

Example $y^2 = (x^2 + 1)/(x^2 - 1)$ is symmetric with respect to the x and y axis, the origin, and the line $y = x$. It has the vertical asymptotes $x = \pm 1$. When $x = 0$, $y^2 = -1$; so there are no y intercepts. If $y = 0$, $(x^2 + 1)/(x^2 - 1) = 0$; so there are no x intercepts. If $|x| < 1$, y^2 is negative; so $|x| > 1$. From $x^2 = (y^2 + 1)/(y^2 - 1)$, $y = \pm 1$ are horizontal asymptotes and $|y| > 1$. As $x \to 1^+$, $y \to +\infty$; as $x \to +\infty$, $y \to +1$. The graph is given in Fig. 3-16.

Conic Sections The curves included in this group are obtained from plane sections of the cone. They include the circle, ellipse, parabola, hyperbola, and degeneratively the point and straight line. A **conic** is the locus of a point whose distance from a fixed point called the **focus** is in a constant ratio to its distance from a fixed line, called the directrix. This ratio is the eccentricity e. If $e = 0$, the conic is a circle; if $0 < e < 1$, the conic is an ellipse; if $e = 1$, the conic is a parabola; if $e > 1$, the conic is a hyperbola. Every conic section is representable by an equation of second degree. Conversely, every equation of second degree in two variables represents a conic. The general equation of the second degree is $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$. Let Δ be defined as the determinant

$$\Delta = \begin{vmatrix} 2A & B & D \\ B & 2C & E \\ D & E & 2F \end{vmatrix}$$

The table characterizes the curve represented by the equation.

	$B^2 - 4AC < 0$	$B^2 - 4AC = 0$	$B^2 - 4AC > 0$
$\Delta \neq 0$	$A\Delta < 0$ $A \neq C$, an ellipse $A\Delta < 0$ $A = C$, a circle $A\Delta > 0$, no locus	Parabola	Hyperbola
$\Delta = 0$	Point	2 parallel lines if $Q = D^2 + E^2 - 4(A + C)F > 0$ 1 straight line if $Q = 0$, no locus if $Q < 0$	2 intersecting straight lines

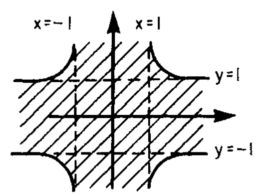

FIG. 3-16 Graph of $y^2 = (x^2 + 1)/(x^2 - 1)$.

Some common equations in parametric form are given below.

Equation	Parametric form	Remarks
(1) $(x-h)^2+(y-k)^2=a^2$	$x=h+a\cos\theta$ $y=k+a\sin\theta$	Circle (Fig. 3-23) Parameter is angle θ.
(2) $\dfrac{(x-h)^2}{a^2}+\dfrac{(y-k)^2}{b^2}=1$	$x=h+a\cos\phi$ $y=k+a\sin\phi$	Ellipse (Fig. 3-20) Parameter is angle ϕ.
(3) $x^2+y^2=a^2$	$\begin{cases} x=\dfrac{-at}{\sqrt{t^2+1}} \\ y=\dfrac{a}{\sqrt{t^2+1}} \end{cases}$	Circle Parameter is $t=\dfrac{dy}{dx}$ = slope of tangent at (x, y).
(4) $x^2=y+k$		Parabola (Fig. 3-22)
(5) $\dfrac{x^2}{a^2}-\dfrac{y^2}{b^2}=1$		Hyperbola with the origin at the center (Fig. 3-21)
(6) $y=a\cosh\dfrac{x}{a}$	$\begin{cases} x=a\sinh^{-1}\dfrac{s}{a} \\ y^2=a^2+s^2 \end{cases}$	Catenary (such as hanging cable under gravity) Parameter s = arc length from $(0, a)$ to (x, y).
(7) Cycloid	$\begin{cases} x=a(\phi-\sin\phi) \\ y=a(1-\cos\phi) \end{cases}$	Fig. 3.24

Example $3x^2+4xy-2y^2+3x-2y+7=0$.

$$\Delta=\begin{vmatrix} 6 & 4 & 3 \\ 4 & -4 & -2 \\ 3 & -2 & 14 \end{vmatrix}=-596\neq 0,\ B^2-4AC=40>0$$

The curve is therefore a hyperbola.

The following tabulation gives the form of the more common equations.

Polar equation	Type of curve
(1) $r=a$	Circle, Fig. 3-17
(2) $r=2a\cos\theta$	Circle, Fig. 3-18
(3) $r=2a\sin\theta$	Circle, Fig. 3-19
(4) $r^2-2br\cos(\theta-\beta)+b^2-a^2=0$	Circle at (b, β), radius a
(5) $r=\dfrac{ke}{1-e\cos\theta}$	$e=1$ parabola, Fig. 3-22 $0<e<1$ ellipse, Fig. 3-20 $e>1$ hyperbola, Fig. 3-21

Parametric Equations It is frequently useful to write the equations of a curve in terms of an auxiliary variable called a parameter. For example, a circle of radius a, center at (0, 0), can be written in the equivalent form $x=a\cos\phi$, $y=a\sin\phi$ where ϕ is the parameter. Similarly, $x=a\cos\phi$, $y=b\sin\phi$ are the parametric equations of the ellipse $x^2/a^2+y^2/b^2=1$ with parameter ϕ.

SOLID ANALYTIC GEOMETRY

Coordinate Systems The commonly used coordinate systems are three in number. Others may be used in specific problems [see Morse, P. M., and H. Feshbach, *Methods of Theoretical Physics*, vols. I and II, McGraw-Hill, New York (1953)]. The **rectangular** (cartesian) system (Fig. 3-25) consists of mutually orthogonal axes x, y, z. A triple of numbers (x, y, z) is used to represent each point. The **cylindrical** coordinate system $(r, \theta, z$; Fig. 3-26) is frequently used to locate a point in space. These are essentially the polar coordinates (r, θ) coupled with the z coordinate. As before, $x=r\cos\theta$, $y=r\sin\theta$, $z=z$ and $r^2=x^2+y^2$, $y/x=\tan\theta$. If r is held constant and θ and z are allowed to vary, the locus of (r, θ, z) is a right circular cylinder of radius r along the z axis. The locus of $r=C$ is a circle, and θ = constant is a plane containing the z axis and making an angle θ with the xz plane. Cylindrical coordinates are convenient to use when the problem has an axis of symmetry.

The **spherical** coordinate system is convenient if there is a point of symmetry in the system. This point is taken as the origin and the coordinates (ρ, ϕ, θ) illustrated in Fig. 3-27. The relations are $x=$

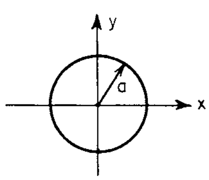

FIG. 3-17 Circle center (0,0) $r=a$.

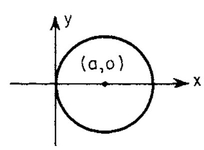

FIG. 3-18 Circle center $(a,0)$ $r=2a\cos\theta$.

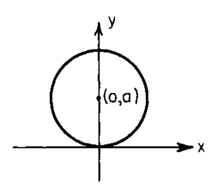

FIG. 3-19 Circle center $(0,a)$ $r=2a\sin\theta$.

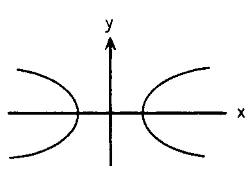

FIG. 3-21 Hyperbola, $e>1$.

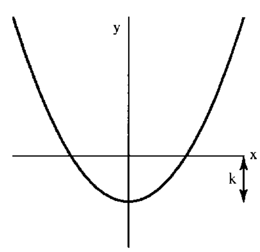

FIG. 3-22 Parabola, $e=1$.

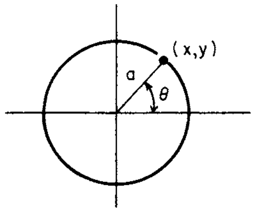

FIG. 3-23 Circle.

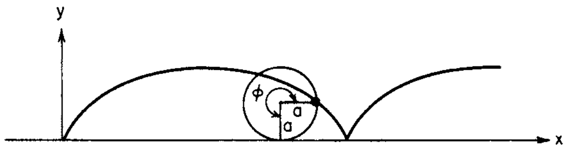

FIG. 3-24 Cycloid.

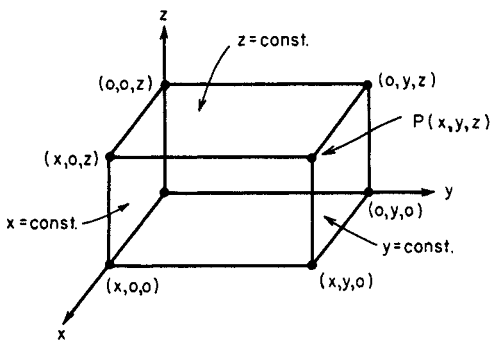

FIG. 3-25 Cartesian coordinates.

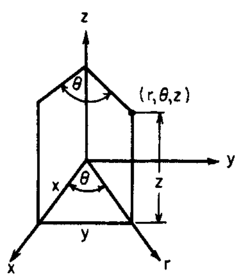

FIG. 3-26 Cylindrical coordinates.

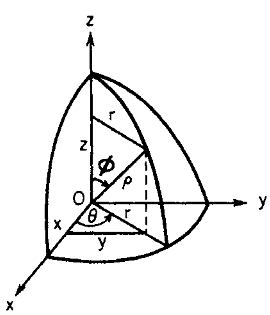

FIG. 3-27 Spherical coordinates.

$\rho \sin \phi \cos \theta$, $y = \rho \sin \phi \sin \theta$, $z = \rho \cos \phi$, and $r = \rho \sin \phi$. θ = constant is a plane containing the z axis and making an angle θ with the xz plane. ϕ = constant is a cone with vertex at 0. ρ = constant is the surface of a sphere of radius ρ, center at the origin 0. Every point in the space may be given spherical coordinates restricted to the ranges $0 \le \phi \le \pi$, $\rho \ge 0$, $0 \le \theta < 2\pi$.

Lines and Planes The distance between two points (x_1, y_1, z_1), (x_2, y_2, z_2) is $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}$. There is nothing in the geometry of three dimensions quite analogous to the slope of a line in the plane case. Instead of specifying the direction of a line by a trigonometric function evaluated for one angle, a trigonometric function evaluated for three angles is used. The angles α, β, γ that a line segment makes with the positive x, y, and z axes, respectively, are called the **direction angles** of the line, and $\cos \alpha$, $\cos \beta$, $\cos \gamma$ are called the **direction cosines.** Let (x_1, y_1, z_1), (x_2, y_2, z_2) be on the line. Then $\cos \alpha = (x_2 - x_1)/d$, $\cos \beta = (y_2 - y_1)/d$, $\cos \gamma = (z_2 - z_1)/d$, where d = the distance between the two points. Clearly $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$. If two lines are specified by the direction cosines $(\cos \alpha_1, \cos \beta_1, \cos \gamma_1)$, $(\cos \alpha_2, \cos \beta_2, \cos \gamma_2)$, then the angle θ between the lines is $\cos \theta = \cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2 + \cos \gamma_1 \cos \gamma_2$. Thus the lines are perpendicular if and only if $\theta = 90°$ or $\cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2 + \cos \gamma_1 \cos \gamma_2 = 0$. The equation of a line with direction cosines $(\cos \alpha, \cos \beta, \cos \gamma)$ passing through (x_1, y_1, z_1) is $(x - x_1)/\cos \alpha = (y - y_1)/\cos \beta = (z - z_1)/\cos \gamma$.

The equation of every plane is of the form $Ax + By + Cz + D = 0$. The numbers

$$\frac{A}{\sqrt{A^2 + B^2 + C^2}}, \frac{B}{\sqrt{A^2 + B^2 + C^2}}, \frac{C}{\sqrt{A^2 + B^2 + C^2}}$$

are direction cosines of the normal lines to the plane. The plane through the point (x_1, y_1, z_1) whose normals have these as direction cosines is $A(x - x_1) + B(y - y_1) + C(z - z_1) = 0$.

Example Find the equation of the plane through (1, 5, −2) perpendicular to the line $(x + 9)/7 = (y - 3)/-1 = z/8$. The numbers (7, −1, 8) are called **direction numbers.** They are a constant multiple of the direction cosines. $\cos \alpha = 7/114$, $\cos \beta = -1/114$, $\cos \gamma = 8/114$. The plane has the equation $7(x - 1) - 1(y - 5) + 8(z + 2) = 0$ or $7x - y + 8z + 14 = 0$.

The distance from the point (x_1, y_1, z_1) to the plane $Ax + By + Cz + D = 0$ is

$$d = \frac{|Ax_1 + By_1 + Cz_1 + D|}{\sqrt{A^2 + B^2 + C^2}}$$

Space Curves Space curves are usually specified as the set of points whose coordinates are given parametrically by a system of equations $x = f(t)$, $y = g(t)$, $z = h(t)$ in the parameter t.

Example The equation of a straight line in space is $(x - x_1)/a = (y - y_1)/b = (z - z_1)/c$. Since all these quantities must be equal (say, to t), we may write $x = x_1 + at$, $y = y_1 + bt$, $z = z_1 + ct$, which represent the parametric equations of the line.

Example The equations $z = a \cos \beta t$, $y = a \sin \beta t$, $z = bt$, a, β, b positive constants, represent a circular helix.

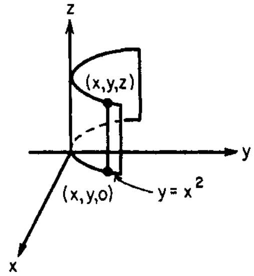

FIG. 3-28 Parabolic cylinder.

Surfaces The locus of points (x, y, z) satisfying $f(x, y, z) = 0$, broadly speaking, may be interpreted as a surface. The simplest surface is the **plane.** The next simplest is a **cylinder,** which is a surface generated by a straight line moving parallel to a given line and passing through a given curve.

Example The parabolic cylinder $y = x^2$ (Fig. 3-28) is generated by a straight line parallel to the z axis passing through $y = x^2$ in the plane $z = 0$.

A surface whose equation is a quadratic in the variables x, y, and z is called a **quadric surface.** Some of the more common such surfaces are tabulated and pictured in Figs. 3-28 to 3-36.

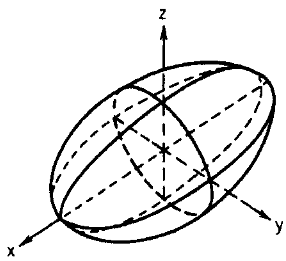

FIG. 3-29 Ellipsoid. $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ (sphere if $a = b = c$)

ANGLES

An angle is generated by the rotation of a line about a fixed center from some initial position to some terminal position. If the rotation is clockwise, the angle is negative; if it is counterclockwise, the angle is positive. Angle size is unlimited. If α, β are two angles such that $\alpha + \beta = 90°$, they are complementary; they are supplementary if $\alpha + \beta = 180°$. Angles are most commonly measured in the sexagesimal system or by radian measure. In the first system there are 360 degrees in one complete revolution; one degree = 1⁄90 of a right angle. The degree is subdivided into 60 minutes; the minute is subdivided into 60 seconds. In the radian system one radian is the angle at the center of a circle subtended by an arc whose length is equal to the radius of the circle. Thus 2π rad = 360°; 1 rad = 57.29578°; 1° = 0.01745 rad; 1 min = 0.00029089 rad. The advantage of radian measure is that it is *dimensionless.* The quadrants are conventionally labeled as Fig. 3-37 shows.

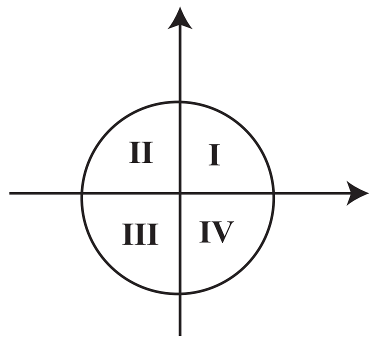

FIG. 3-37 Quadrants.

FUNCTIONS OF CIRCULAR TRIGONOMETRY

The trigonometric functions of angles are the ratios between the various sides of the reference triangles shown in Fig. 3-38 for the various quadrants. Clearly $r = \sqrt{x^2 + y^2} \geq 0$. The fundamental functions (see Figs. 3-39, 3-40, 3-41) are

Plane Trigonometry

Sine of $\theta = \sin\theta = y/r$	Secant of $\theta = \sec\theta = r/x$
Cosine of $\theta = \cos\theta = x/r$	Cosecant of $\theta = \csc\theta = r/y$
Tangent of $\theta = \tan\theta = y/x$	Cotangent of $\theta = \cot\theta = x/y$

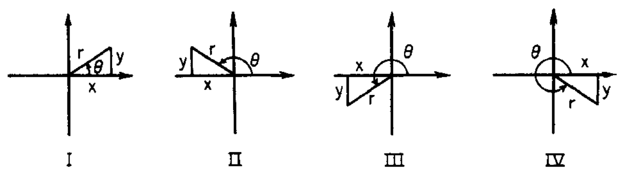

FIG. 3-38 Triangles.

Values of the Trigonometric Functions for Common Angles

θ°	θ, rad	sin θ	cos θ	tan θ
0	0	0	1	0
30	$\pi/6$	1/2	$\sqrt{3}/2$	$\sqrt{3}/3$
45	$\pi/4$	$\sqrt{2}/2$	$\sqrt{2}/2$	1
60	$\pi/3$	$\sqrt{3}/2$	1/2	$\sqrt{3}$
90	$\pi/2$	1	0	$+\infty$

If $90° \leq \theta \leq 180°$, $\sin\theta = \sin(180° - \theta)$; $\cos\theta = -\cos(180° - \theta)$; $\tan\theta = -\tan(180° - \theta)$. If $180° \leq \theta \leq 270°$, $\sin\theta = -\sin(270° - \theta)$; $\cos\theta = -\cos(270° - \theta)$; $\tan\theta = \tan(270° - \theta)$. If $270° \leq \theta \leq 360°$, $\sin\theta = -\sin(360° - \theta)$; $\cos\theta = \cos(360° - \theta)$; $\tan\theta = -\tan(360° - \theta)$. The reciprocal properties may be used to find the values of the other functions.

If it is desired to find the angle when a function of it is given, the procedure is as follows: There will in general be two angles between 0° and 360° corresponding to the given value of the function.

Given ($a > 0$)	Find an acute angle θ_0 such that	Required angles are
$\sin\theta = +a$	$\sin\theta_0 = a$	θ_0 and $(180° - \theta_0)$
$\cos\theta = +a$	$\cos\theta_0 = a$	θ_0 and $(360° - \theta_0)$
$\tan\theta = +a$	$\tan\theta_0 = a$	θ_0 and $(180° + \theta_0)$
$\sin\theta = -a$	$\sin\theta_0 = a$	$180° + \theta_0$ and $360° - \theta_0$
$\cos\theta = -a$	$\cos\theta_0 = a$	$180° - \theta_0$ and $180° + \theta_0$
$\tan\theta = -a$	$\tan\theta_0 = a$	$180° - \theta_0$ and $360° - \theta_0$

Relations between Functions of a Single Angle $\sec\theta = 1/\cos\theta$; $\csc\theta = 1/\sin\theta$, $\tan\theta = \sin\theta/\cos\theta = \sec\theta/\csc\theta = 1/\cot\theta$; $\sin^2\theta + \cos^2\theta = 1$; $1 + \tan^2\theta = \sec^2\theta$; $1 + \cot^2\theta = \csc^2\theta$. For $0 \leq \theta \leq 90°$ the following results hold:

$$\sin\theta = 2\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right)$$

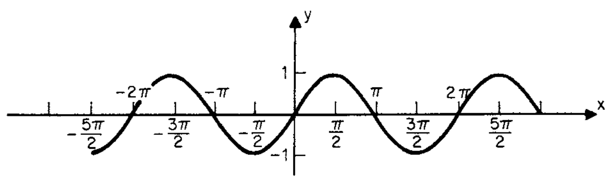

FIG. 3-39 Graph of $y = \sin x$.

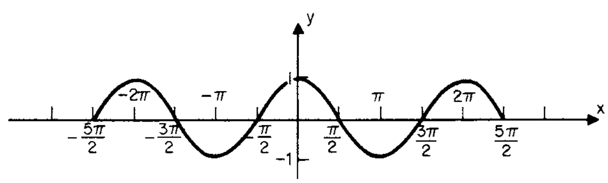

FIG. 3-40 Graph of $y = \cos x$.

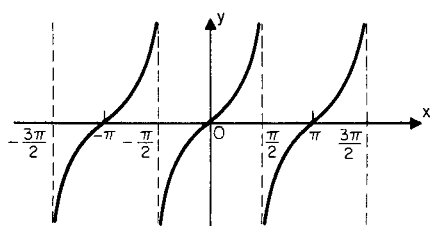

FIG. 3-41 Graph of $y = \tan x$.

$$\text{and}\quad \cos\theta = \cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right)$$

The cofunction property is very important. $\cos\theta = \sin(90° - \theta)$, $\sin\theta = \cos(90° - \theta)$, $\tan\theta = \cot(90° - \theta)$, $\cot\theta = \tan(90° - \theta)$, etc.

Functions of Negative Angles $\sin(-\theta) = -\sin\theta$, $\cos(-\theta) = \cos\theta$, $\tan(-\theta) = -\tan\theta$, $\sec(-\theta) = \sec\theta$, $\csc(-\theta) = -\csc\theta$, $\cot(-\theta) = -\cot\theta$.

Identities

Sum and Difference Formulas Let x, y be two angles. $\sin(x \pm y) = \sin x\cos y \pm \cos x\sin y$; $\cos(x \pm y) = \cos x\cos y \mp \sin x\sin y$; $\tan(x \pm y) = (\tan x \pm \tan y)/(1 \mp \tan x\tan y)$; $\sin x \pm \sin y = 2\sin\frac{1}{2}(x \pm y)\cos\frac{1}{2}(x \mp y)$; $\cos x + \cos y = 2\cos\frac{1}{2}(x + y)\cos\frac{1}{2}(x - y)$; $\cos x - \cos y = -2\sin\frac{1}{2}(x + y)\sin\frac{1}{2}(x - y)$; $\tan x \pm \tan y = [\sin(x \pm y)]/(\cos x\cos y)$; $\sin^2 x - \sin^2 y = \cos^2 y - \cos^2 x = \sin(x + y)\sin(x - y)$; $\cos^2 x - \sin^2 y = \cos^2 y - \sin^2 x = \cos(x + y)\cos(x - y)$; $\sin(45° + x) = \cos(45° - x)$; $\sin(45° - x) = \cos(45° + x)$; $\tan(45° \pm x) = \cot(45° \mp x)$.

Multiple and Half Angle Identities Let x = angle, $\sin 2x = 2\sin x\cos x$; $\sin x = 2\sin\frac{1}{2}x\cos\frac{1}{2}x$; $\cos 2x = \cos^2 x - \sin^2 x = 1 - 2\sin^2 x = 2\cos^2 x - 1$. $\tan 2x = (2\tan x)/(1 - \tan^2 x)$; $\sin 3x = 3\sin x - 4\sin^3 x$; $\cos 3x = 4\cos^3 x - 3\cos x$. $\tan 3x = (3\tan x - \tan^3 x)/(1 - 3\tan^2 x)$; $\sin 4x = 4\sin x\cos x - 8\sin^3 x\cos x$; $\cos 4x = 8\cos^4 x - 8\cos^2 x + 1$.

$$\sin\left(\frac{x}{2}\right) = \sqrt{\tfrac{1}{2}(1 - \cos x)}$$

$$\cos\left(\frac{x}{2}\right) = \sqrt{\tfrac{1}{2}(1 + \cos x)}$$

$$\tan\left(\frac{x}{2}\right) = \sqrt{\frac{1 - \cos x}{1 + \cos x}} = \frac{\sin x}{1 + \cos x} = \frac{1 - \cos x}{\sin x}$$

INVERSE TRIGONOMETRIC FUNCTIONS

$y = \sin^{-1} x = \arcsin x$ is the angle y whose sine is x.

Example $y = \sin^{-1}\frac{1}{2}$, y is 30°.

The complete solution of the equation $x = \sin y$ is $y = (-1)^n \sin^{-1} x + n(180°)$, $-\pi/2 \le \sin^{-1} x \le \pi/2$ where $\sin^{-1} x$ is the principal value of the angle whose sine is x. The range of principal values of the $\cos^{-1} x$ is $0 \le \cos^{-1} x \le \pi$ and $-\pi/2 \le \tan^{-1} x \le \pi/2$. If these restrictions are allowed to hold, the following formulas result:

$$\sin^{-1} x = \cos^{-1}\sqrt{1 - x^2} = \tan^{-1}\frac{x}{\sqrt{1 - x^2}} = \cot^{-1}\frac{\sqrt{1 - x^2}}{x}$$

$$= \sec^{-1}\frac{1}{\sqrt{1 - x^2}} = \csc^{-1}\frac{1}{x} = \frac{\pi}{2} - \cos^{-1} x$$

$$\cos^{-1} x = \sin^{-1}\sqrt{1 - x^2} = \tan^{-1}\frac{\sqrt{1 - x^2}}{x}$$

$$= \cot^{-1}\frac{x}{\sqrt{1 - x^2}} = \sec^{-1}\frac{1}{x}$$

$$= \csc^{-1}\frac{1}{\sqrt{1 - x^2}} = \frac{\pi}{2} - \sin^{-1} x$$

$$\tan^{-1} x = \sin^{-1}\frac{x}{\sqrt{1 - x^2}} = \cos^{-1}\frac{1}{\sqrt{1 + x^2}}$$

$$= \cot^{-1}\frac{1}{x} = \sec^{-1}\sqrt{1 + x^2} = \csc^{-1}\frac{\sqrt{1 + x^2}}{x}$$

RELATIONS BETWEEN ANGLES AND SIDES OF TRIANGLES

Solutions of Triangles (Fig. 3-42) Let a, b, c denote the sides and α, β, γ the angles opposite the sides in the triangle. Let $2s = a + b + c$, A = area, r = radius of the inscribed circle, R = radius of the circumscribed circle, and h = altitude. In any triangle $\alpha + \beta + \gamma = 180°$.

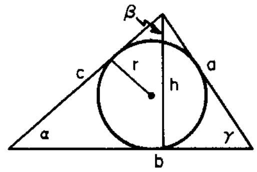

FIG. 3-42 Triangle.

Law of Sines $\sin\alpha/a = \sin\beta/b = \sin\gamma/c = 1/(2R)$.

Law of Tangents

$$\frac{a + b}{a - b} = \frac{\tan\frac{1}{2}(\alpha + \beta)}{\tan\frac{1}{2}(\alpha - \beta)};\ \frac{b + c}{b - c} = \frac{\tan\frac{1}{2}(\beta + \gamma)}{\tan\frac{1}{2}(\beta - \gamma)};\ \frac{a + c}{a - c} = \frac{\tan\frac{1}{2}(\alpha + \gamma)}{\tan\frac{1}{2}(\alpha - \gamma)}$$

Law of Cosines $a^2 = b^2 + c^2 - 2bc\cos\alpha$; $b^2 = a^2 + c^2 - 2ac\cos\beta$; $c^2 = a^2 + b^2 - 2ab\cos\gamma$.

Other Relations In this subsection, where appropriate, two more formulas can be generated by replacing a by b, b by c, c by a, α by β, β by γ, and γ by α. $\cos\alpha = (b^2 + c^2 - a^2)/2bc$; $a = b\cos\gamma + c\cos\beta$; $\sin\alpha = (2/bc)\sqrt{s(s - a)(s - b)(s - c)}$;

$$\sin\left(\frac{\alpha}{2}\right) = \sqrt{\frac{(s - b)(s - c)}{bc}};\ \cos\left(\frac{\alpha}{2}\right) = \sqrt{\frac{s(s - a)}{bc}};$$

$$A = \frac{1}{2}bh = \frac{1}{2}ab\sin\gamma = \frac{a^2\sin\beta\sin\gamma}{2\sin\alpha} = \sqrt{s(s - a)(s - b)(s - c)} = rs$$

$$\text{where}\quad r = \sqrt{\frac{(s - a)(s - b)(s - c)}{s}}$$

$$R = a/(2\sin\alpha) = abc/4A;\ h = c\sin a = a\sin\gamma = 2rs/b.$$

Right Triangle (Fig. 3-43) Given one side and any acute angle α or any two sides, the remaining parts can be obtained from the following formulas:

$$a = \sqrt{(c + b)(c - b)} = c\sin\alpha = b\tan\alpha$$

$$b = \sqrt{(c + a)(c - a)} = c\cos\alpha = a\cot\alpha$$

$$c = \sqrt{a^2 + b^2},\ \sin\alpha = \frac{a}{c},\ \cos\alpha = \frac{b}{c},\ \tan\alpha = \frac{a}{b},\ \beta = 90° - \alpha$$

$$A = \frac{1}{2}ab = \frac{a^2}{2\tan\alpha} = \frac{b^2\tan\alpha}{2} = \frac{c^2\sin 2\alpha}{4}$$

Oblique Triangles (Fig. 3-44) There are four possible cases.

1. Given b, c and the included angles α,

$$\frac{1}{2}(\beta + \gamma) = 90° - \frac{1}{2}\alpha;\ \tan\frac{1}{2}(\beta - \gamma) = \frac{b - c}{b + c}\tan\frac{1}{2}(\beta + \gamma)$$

$$\beta = \frac{1}{2}(\beta + \gamma) + \frac{1}{2}(\beta - \gamma);\ \gamma = \frac{1}{2}(\beta + \gamma) - \frac{1}{2}(\beta - \gamma);\ a = \frac{b\sin\alpha}{\sin\beta}$$

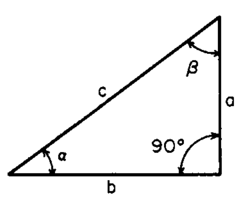

FIG. 3-43 Right triangle.

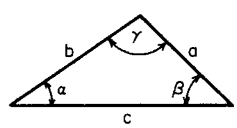

FIG. 3-44 Oblique triangle.

2. Given the three sides $a, b, c, s = \frac{1}{2}(a + b + c)$;

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$$

$$\tan \frac{1}{2}\alpha = \frac{r}{s-a}; \tan \frac{1}{2}\beta = \frac{r}{s-b}; \tan \frac{1}{2}\gamma = \frac{r}{s-c}$$

3. Given any two sides a, c and an angle opposite one of them α, $\sin \gamma = (c \sin \alpha)/a$; $\beta = 180° - a - \gamma$; $b = (a \sin \beta)/(\sin \alpha)$. There may be two solutions here. γ may have two values γ_1, γ_2; $\gamma_1 < 90°$, $\gamma_2 = 180° - \gamma_1 > 90°$. If $\alpha + \gamma_2 > 180°$, use only γ_1. This case may be *impossible* if $\sin \gamma > 1$.

4. Given any side c and two angles α and β, $\gamma = 180° - \alpha - \beta$; $a = (c \sin \alpha)/(\sin \gamma)$; $b = (c \sin \beta)/(\sin \gamma)$.

HYPERBOLIC TRIGONOMETRY

The hyperbolic functions are certain combinations of exponentials e^x and e^{-x}.

$$\cosh x = \frac{e^x + e^{-x}}{2}; \sinh x = \frac{e^x - e^{-x}}{2}; \tanh x = \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\coth x = \frac{e^x + e^{-x}}{e^x - e^{-x}} = \frac{1}{\tanh x} = \frac{\cosh x}{\sinh x}; \operatorname{sech} x = \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}};$$

$$\operatorname{csch} x = \frac{1}{\sinh x} = \frac{2}{e^x - e^{-x}}$$

Fundamental Relationships $\sinh x + \cosh x = e^x$; $\cosh x - \sinh x = e^{-x}$; $\cosh^2 x - \sinh^2 x = 1$; $\operatorname{sech}^2 x + \tanh^2 x = 1$; $\coth^2 x - \operatorname{csch}^2 x = 1$; $\sinh 2x = 2 \sinh x \cosh x$; $\cosh 2x = \cosh^2 x + \sinh^2 x = 1 + 2 \sinh^2 x = 2 \cosh^2 x - 1$. $\tanh 2x = (2 \tanh x)/(1 + \tanh^2 x)$; $\sinh (x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y$; $\cosh (x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y$; $2 \sinh^2 x/2 = \cosh x - 1$; $2 \cosh^2 x/2 = \cosh x + 1$; $\sinh (-x) = -\sinh x$; $\cosh (-x) = \cosh x$; $\tanh (-x) = -\tanh x$.

When $u = a \cosh x$, $v = a \sinh x$, then $u^2 - v^2 = a^2$; which is the equation for a hyperbola. In other words, the hyperbolic functions in the parametric equations $u = a \cosh x$, $v = a \sinh x$ have the same relation to the hyperbola $u^2 - v^2 = a^2$ that the equations $u = a \cos \theta$, $v = a \sin \theta$ have to the circle $u^2 + v^2 = a^2$.

Inverse Hyperbolic Functions If $x = \sinh y$, then y is the inverse hyperbolic sine of x written $y = \sinh^{-1} x$ or arcsinh x. $\sinh^{-1} x = \log_e (x + \sqrt{x^2 + 1})$

$$\cosh^{-1} x = \log_e (x + \sqrt{x^2 - 1}); \tanh^{-1} x = \frac{1}{2} \log_e \frac{1 + x}{1 - x};$$

$$\coth^{-1} x = \frac{1}{2} \log_e \frac{x + 1}{x - 1}; \operatorname{sech}^{-1} x = \log_e \left(\frac{1 + \sqrt{1 - x^2}}{x}\right);$$

$$\operatorname{csch}^{-1} = \log_e \left(\frac{1 + \sqrt{1 + x^2}}{x}\right)$$

Magnitude of the Hyperbolic Functions $\cosh x \geq 1$ with equality only for $x = 0$; $-\infty < \sinh x < \infty$; $-1 < \tanh x < 1$. $\cosh x \sim e^x/2$ as $x \to \infty$; $\sinh x \to e^x/2$ as $x \to \infty$.

APPROXIMATIONS FOR TRIGONOMETRIC FUNCTIONS

For small values of θ (θ measured in radians) $\sin \theta \approx \theta$, $\tan \theta \approx \theta$; $\cos \theta \approx 1 - (\theta^2/2)$. The behavior ratio of the functions as $\theta \to 0$ is given by the following:

$$\lim_{\theta \to 0} \sin \theta/\theta = 1; \sin \theta/\tan \theta = 1.$$

DIFFERENTIAL AND INTEGRAL CALCULUS

DIFFERENTIAL CALCULUS

An Example of Functional Notation Suppose that a storage warehouse of 16,000 ft^3 is required. The construction costs per square foot are \$10, \$3, and \$2 for walls, roof, and floor respectively. What are the minimum cost dimensions? Thus, with h = height, x = width, and y = length, the respective costs are

$$\text{Walls} = 2 \times 10hy + 2 \times 10hx = 20h(y + x)$$

$$\text{Roof} = 3xy$$

$$\text{Floor} = 2xy$$

$$\text{Total cost} = 2xy + 3xy + 20h(x + y) = 5xy + 20h(x + y) \tag{3-1}$$

and the restriction

$$\text{Total volume} = xyh \tag{3-2}$$

Solving for h from Eq. (3-2),

$$h = \text{volume}/xy = 16{,}000/xy \tag{3-3}$$

$$\text{Cost} = 5xy + \frac{320{,}000}{xy}(y + x) = 5xy + 320{,}000\left(\frac{1}{x} + \frac{1}{y}\right) \tag{3-4}$$

In this form it can be shown that the minimum cost will occur for $x = y$; therefore

$$\text{Cost} = 5x^2 + 640{,}000\ (1/x)$$

By evaluation, the smallest cost will occur when $x = 40$.

$$\text{Cost} = 5(1600) + 640{,}000/40 = \$24{,}000$$

The dimensions are then $x = 40$ ft, $y = 40$ ft, $h = 16{,}000/(40 \times 40) = 10$ ft. Symbolically, the original cost relationship is written

$$\text{Cost} = f(x, y, h) = 5xy + 20h(y + x)$$

and the volume relation

$$\text{Volume} = g(x, y, h) = xyh = 16{,}000$$

In terms of the derived general relationships (3-1) and (3-2), x, y, and h are **independent variables—**cost and volume, **dependent variables.** That is, the cost and volume become fixed with the specification of dimensions. However, corresponding to the given restriction of the problem, relative to volume, the function $g(x, y, z) = xyh$ becomes a constraint function. In place of three independent and two dependent variables the problem reduces to two independent (volume has been constrained) and two dependent as in functions (3-3) and (3-4). Further, the requirement of minimum cost reduces the problem to three dependent variables (x, y, h) and no **degrees of freedom,** that is, freedom of independent selection.

Limits The limit of function $f(x)$ as x approaches a (a is finite or else x is said to increase without bound) is the number N.

$$\lim_{x \to a} f(x) = N$$

This states that $f(x)$ can be calculated as close to N as desirable by making x sufficiently close to a. This does not put any restriction on $f(x)$ when $x = a$. Alternatively, for any given positive number ε, a number δ can be found such that $0 < |a - x| < \delta$ implies that $|N - f(x)| < \varepsilon$.

The following operations with limits (when they exist) are valid:

$$\lim_{x \to a} bf(x) = b \lim_{x \to a} f(x)$$

$$\lim_{x \to a} [f(x) + g(x)] = \lim_{x \to a} f(x) + \lim_{x \to a} g(x)$$

$$\lim_{x\to a}[f(x)g(x)] = \lim_{x\to a} f(x)\cdot \lim_{x\to a} g(x)$$

$$\lim_{x\to a}\frac{f(x)}{g(x)} = \frac{\lim_{x\to a} f(x)}{\lim_{x\to a} g(x)} \quad \text{if} \quad \lim_{x\to a} g(x) \neq 0$$

See "Indeterminant Forms" below when $g(a) = 0$.

Continuity A function $f(x)$ is continuous at the point $x = a$ if

$$\lim_{h\to 0}[f(a+h) - f(a)] = 0$$

Rigorously, it is stated $f(x)$ is continuous at $x = a$ if for any positive ε there exists a $\delta > 0$ such that $|f(a+h) - f(a)| < \varepsilon$ for all x with $|x - a| < \delta$. For example, the function $(\sin x)/x$ is not continuous at $x = 0$ and therefore is said to be discontinuous. Discontinuities are classified into three types:

1. Removable $y = \sin x/x$ at $x = 0$
2. Infinite $y = 1/x$ at $x = 0$
3. Jump $y = 10/(1 + e^{1/x})$ at $x = 0^+$ $y = 0^+$; $x = 0$ $y = 0$; $x = 0^-$ $y = 10$

Derivative The function $f(x)$ has a derivative at $x = a$, which can be denoted as $f'(a)$, if

$$\lim_{h\to 0}\frac{f(a+h) - f(a)}{h}$$

exists. This implies continuity at $x = a$. Conversely, a function may be continuous but not have a derivative. The derivative function is

$$f'(x) = \frac{df}{dx} = \lim_{h\to 0}\frac{f(x+h) - f(x)}{h}$$

Differentiation Define $\Delta y = f(x + \Delta x) - f(x)$. Then dividing by Δx

$$\frac{\Delta y}{\Delta x} = \frac{f(x+\Delta x) - f(x)}{\Delta x}$$

Call
$$\lim_{\Delta x\to 0}\frac{\Delta y}{\Delta x} = \frac{dy}{dx}$$

then
$$\frac{dy}{dx} = \lim_{\Delta x\to 0}\frac{f(x+\Delta x) - f(x)}{\Delta x}$$

Example Find the derivative of $y = \sin x$.

$$\begin{aligned}\frac{dy}{dx} &= \lim_{\Delta x\to 0}\frac{\sin(x+\Delta x) - \sin(x)}{\Delta x}\\ &= \lim_{\Delta x\to 0}\frac{\sin x\cos\Delta x + \sin\Delta x\cos x - \sin x}{\Delta x}\\ &= \lim_{\Delta x\to 0}\frac{\sin x(\cos\Delta x - 1)}{\Delta x} + \lim_{\Delta x\to 0}\frac{\sin\Delta x\cos x}{\Delta x}\\ &= \cos x \text{ since } \lim_{\Delta x\to 0}\frac{\sin\Delta x}{\Delta x} = 1\end{aligned}$$

Differential Operations The following differential operations are valid: $f, g, \ldots$ are differentiable functions of x, c and n are constants; e is the base of the natural logarithms.

$$\frac{dc}{dx} = 0 \tag{3-5}$$

$$\frac{dx}{dx} = 1 \tag{3-6}$$

$$\frac{d}{dx}(f+g) = \frac{df}{dx} + \frac{dg}{dx} \tag{3-7}$$

$$\frac{d}{dx}(f\times g) = f\frac{dg}{dx} + g\frac{df}{dx} \tag{3-8}$$

$$\frac{dy}{dx} = \frac{1}{dx/dy} \quad \text{if} \quad \frac{dx}{dy} \neq 0 \tag{3-9}$$

$$\frac{d}{dx}f^n = nf^{n-1}\frac{df}{dx} \tag{3-10}$$

$$\frac{d}{dx}\left(\frac{f}{g}\right) = \frac{g(df/dx) - f(dg/dx)}{g^2} \tag{3-11}$$

$$\frac{df}{dx} = \frac{df}{dv}\times\frac{dv}{dx} \quad \text{(chain rule)} \tag{3-12}$$

$$\frac{df^g}{dx} = gf^{g-1}\frac{df}{dx} + f^g\ln f\frac{dg}{dx} \tag{3-13}$$

$$\frac{da^x}{dx} = (\ln a)\,a^x \tag{3-14}$$

Example Derive dy/dx for $x^2 + y^3 = x + xy + A$.

Here
$$\frac{d}{dx}x^2 + \frac{d}{dx}y^3 = \frac{d}{dx}x + \frac{d}{dx}xy + \frac{d}{dx}A$$

$$2x + 3y^2\frac{dy}{dx} = 1 + y + x\frac{dy}{dx} + 0$$

by rules (3-10), (3-10), (3-6), (3-8), and (3-5) respectively.

Thus
$$\frac{dy}{dx} = \frac{2x - 1 - y}{x - 3y^2}$$

Differentials

$$de^x = e^x\,dx \tag{3-15a}$$
$$d(a^x) = a^x\log a\,dx \tag{3-15b}$$

$$d\tanh x = \text{sech}^2 x\,dx \tag{3-32}$$
$$d\coth x = -\text{csch}^2 x\,dx \tag{3-33}$$
$$d\,\text{sech}\,x = -\text{sech}\,x\tanh x\,dx \tag{3-34}$$
$$d\,\text{csch}\,x = -\text{csch}\,x\coth x\,dx \tag{3-35}$$
$$d\sinh^{-1} x = (x^2 + 1)^{-1/2}\,dx \tag{3-36}$$
$$d\cosh^{-1} = (x^2 - 1)^{-1/2}\,dx \tag{3-37}$$
$$d\tanh^{-1} x = (1 - x^2)^{-1}\,dx \tag{3-38}$$
$$d\coth^{-1} x = -(x^2 - 1)^{-1}\,dx \tag{3-39}$$
$$d\,\text{sech}^{-1} x = -(1/x)(1 - x^2)^{-1/2}\,dx \tag{3-40}$$
$$d\,\text{csch}^{-1} x = -x^{-1}(x^2 + 1)^{-1/2}\,dx \tag{3-41}$$

Example Find dy/dx for $y = \sqrt{x}\cos(1 - x^2)$.

Using

$$\frac{dy}{dx} = \sqrt{x}\frac{d}{dx}\cos(1 - x^2) + \cos(1 - x^2)\frac{d}{dx}\sqrt{x} \qquad \text{(3-8)}$$

$$\frac{d}{dx}\cos(1 - x^2) = -\sin(1 - x^2)\frac{d}{dx}(1 - x^2) \qquad \text{(3-19)}$$

$$= -\sin(1 - x^2)(0 - 2x) \qquad \text{(3-5), (3-10)}$$

$$\frac{d\sqrt{x}}{dx} = \frac{1}{2}x^{-1/2} \qquad \text{(3-10)}$$

$$\frac{dy}{dx} = 2x^{3/2}\sin(1 - x^2) + \frac{1}{2}x^{-1/2}\cos(1 - x^2)$$

Example Find the derivative of $\tan x$ with respect to $\sin x$.

$$v = \sin x$$

$$y = \tan x$$

Using

$$\frac{d\tan x}{d\sin x} = \frac{dy}{dv} = \frac{dy}{dx}\frac{dx}{dv} \qquad \text{(3-12)}$$

$$= \frac{d\tan x}{dx}\frac{1}{\frac{d\sin x}{dx}} \qquad \text{(3-9)}$$

$$= \sec^2 x/\cos x \qquad \text{(3-18), (3-20)}$$

Very often in experimental sciences and engineering functions and their derivatives are available only through their numerical values. In particular, through measurements we may know the values of a function and its derivative only at certain points. In such cases the preceding operational rules for derivatives, including the chain rule, can be applied numerically.

Example Given the following table of values for differentiable functions f and g; evaluate the following quantities:

x	$f(x)$	$f'(x)$	$g(x)$	$g'(x)$
1	3	1	4	−4
3	0	2	4	7
4	−2	10	3	6

$$\frac{d}{dx}[f(x) + g(x)]|_{x=4} = f'(4) + g'(4) = 10 + 6 = 16$$

$$\left(\frac{f}{g}\right)'(1) = \frac{f'(1)g(1) - f(1)g'(1)}{[g(1)]^2} = \frac{1\cdot 4 - 3(-4)}{(4)^2} = \frac{16}{16} = 1$$

Higher Differentials The first derivative of $f(x)$ with respect to x is denoted by f' or df/dx. The derivative of the first derivative is called the second derivative of $f(x)$ with respect to x and is denoted by f'', $f^{(2)}$, or d^2f/dx^2; and similarly for the higher-order derivatives.

Example Given $f(x) = 3x^3 + 2x + 1$, calculate all derivative values at $x = 3$.

$$\frac{df(x)}{dx} = 9x^2 + 2 \qquad x = 3, f'(3) = 9(9) + 2 = 83$$

$$\frac{d^2f(x)}{dx^2} = 18x \qquad x = 3, f''(3) = 18(3) = 54$$

$$\frac{d^3f(x)}{dx^3} = 18 \qquad x = 3, f'''(3) = 18$$

$$\frac{d^nf(x)}{dx^n} = 0 \qquad \text{for } n \ge 4$$

If $f'(x) > 0$ on (a, b), then f is increasing on (a, b). If $f'(x) < 0$ on (a, b), then f is decreasing on (a, b).

The graph of a function $y = f(x)$ is concave up if f' is increasing on (a, b); it is concave down if f' is decreasing on (a, b).

If $f''(x)$ exists on (a, b) and if $f''(x) > 0$, then f is concave up on (a, b). If $f''(x) < 0$, then f is concave down on (a, b).

An inflection point is a point at which a function changes the direction of its concavity.

Indeterminate Forms: L'Hospital's Theorem Forms of the type 0/0, ∞/∞, 0 × ∞, etc., are called indeterminates. To find the limiting values that the corresponding functions approach, L'Hospital's theorem is useful: If two functions $f(x)$ and $g(x)$ both become zero at $x = a$, then the limit of their quotient is equal to the limit of the quotient of their separate derivatives, if the limit exists, or is $+\infty$ or $-\infty$.

Example Find $\lim_{n\to 0}\frac{\sin x}{x}$.

Here
$$\lim_{x\to 0}\frac{\sin x}{x} = \lim_{x\to 0}\frac{d\sin x}{dx} = \lim_{x\to 0}\frac{\cos x}{1} = 1$$

Example Find $\lim_{x\to\infty}\frac{(1.1)^x}{x^{1000}}$.

$$\lim_{x\to\infty}\frac{(1.1)^x}{x^{1000}} = \lim_{x\to\infty}\frac{d(1.1)^x}{dx^{1000}} = \lim_{x\to\infty}\frac{(\ln 1.1)(1.1)^x}{1000x^{999}}$$

Obviously $\lim_{x\to\infty}\frac{1.1^x}{x^{1000}} = \infty$ since repeated application of the rule will reduce the denominator to a finite number 1000! while the numerator remains infinitely large.

Example Find $\lim_{x\to\infty} x^3 e^{-x}$.

$$\lim_{x\to\infty} x^3 e^{-x} = \lim_{x\to\infty}\frac{x^3}{e^x} = \lim_{x\to\infty}\frac{6}{e^x} = 0$$

Example Find $\lim_{x\to 0}(1 - x)^{1/x}$.

Let
$$y = (1 - x)^{1/x}$$

$$\ln y = (1/x)\ln(1 - x)$$

$$\lim_{x\to 0}(\ln y) = \lim_{x\to 0}\frac{\ln(1 - x)}{x} = -1$$

Therefore,
$$\lim_{x\to 0} y = e^{-1}$$

Partial Derivative The abbreviation $z = f(x, y)$ means that z is a function of the two variables x and y. The derivative of z with respect to x, treating y as a constant, is called the partial derivative with respect to x and is usually denoted as $\partial z/\partial x$ or $\partial f(x, y)/\partial x$ or simply f_x. Partial differentiation, like full differentiation, is quite simple to apply. Conversely, the solution of partial differential equations is appreciably more difficult than that of differential equations.

Example Find $\partial z/\partial x$ and $\partial z/\partial y$ for $z = ye^{x^2} + xe^y$.

$$\frac{\partial z}{\partial x} = y\frac{\partial e^{x^2}}{\partial x} + e^y\frac{\partial x}{\partial x} \qquad \frac{\partial z}{\partial y} = e^{x^2}\frac{\partial y}{\partial y} + x\frac{\partial e^y}{\partial y}$$

$$= 2xye^{x^2} + e^y \qquad = e^{x^2} + xe^y$$

Order of Differentiation It is generally true that the order of differentiation is immaterial for any number of differentiations or variables provided the function and the appropriate derivatives are continuous. For $z = f(x, y)$ it follows:

$$\frac{\partial^3 f}{\partial y^2\,\partial x} = \frac{\partial^3 f}{\partial y\,\partial x\,\partial y} = \frac{\partial^3 f}{\partial x\,\partial y^2}$$

General Form for Partial Differentiation

1. Given $f(x, y) = 0$ and $x = g(t)$, $y = h(t)$.

Then
$$\frac{df}{dt} = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt}$$

$$\frac{d^2f}{dt^2} = \frac{\partial^2 f}{\partial x^2}\left(\frac{dx}{dt}\right)^2 + 2\frac{\partial^2 f}{\partial x\,\partial y}\frac{dx}{dt}\frac{dy}{dt} + \frac{\partial^2 f}{\partial y^2}\left(\frac{dy}{dt}\right)^2 + \frac{\partial f}{\partial x}\frac{d^2x}{dt^2} + \frac{\partial f}{\partial y}\frac{d^2y}{dt^2}$$

Example Find df/dt for $f = xy$, $x = \rho \sin t$, $y = \rho \cos t$.

$$\frac{df}{dt} = \frac{\partial(xy)}{\partial x}\left(\frac{d\rho \sin t}{dt}\right) + \frac{\partial(xy)}{\partial y}\left(\frac{d\rho \cos t}{dt}\right)$$
$$= y(\rho \cos t) + x(-\rho \sin t)$$
$$= \rho^2 \cos^2 t - \rho^2 \sin^2 t$$

2. Given $f(x, y) = 0$ and $x = g(t, s)$, $y = h(t, s)$.

Then
$$\frac{\partial f}{\partial t} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial t}$$
$$\frac{\partial f}{\partial s} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial s}$$

Differentiation of Composite Function

Rule 1. Given $f(x, y) = 0$, then $\frac{dy}{dx} = -\frac{\partial f/\partial x}{\partial f/\partial y}\left(\frac{\partial f}{\partial y} \neq 0\right)$.

Rule 2. Given $f(u) = 0$ where $u = g(x)$, then

$$\frac{df}{dx} = f'(u)\frac{du}{dx}$$
$$\frac{d^2 f}{dx^2} = f''(u)\left(\frac{du}{dx}\right)^2 + f'(u)\frac{d^2 u}{dx^2}$$

Example Find df/dx for $f = \sin^2 u$ and $u = \sqrt{1 - x^2}$

$$\frac{df}{dx} = \frac{d \sin^2 u}{du}\frac{d\sqrt{1-x^2}}{dx}$$
$$= 2 \sin u \cos u \left(\frac{1}{2}\right)(-2x)(1 - x^2)^{-1/2}$$
$$= -2\frac{\sqrt{1-u^2}}{u} \sin u \cos u$$

Rule 3. Given $f(u) = 0$ where $u = g(x,y)$, then

$$\frac{\partial f}{\partial x} = f'(u)\frac{\partial u}{\partial x} \qquad \frac{\partial f}{\partial y} = f'(u)\frac{\partial u}{\partial y}$$
$$\frac{\partial^2 f}{\partial x^2} = f''\left(\frac{\partial u}{\partial x}\right)^2 + f'\frac{\partial^2 u}{\partial x^2}$$
$$\frac{\partial^2 f}{\partial x\,\partial y} = f''\frac{\partial u}{\partial x}\frac{\partial u}{\partial y} + f'\frac{\partial^2 u}{\partial x\,\partial y}$$
$$\frac{\partial^2 f}{\partial y^2} = f''\left(\frac{\partial u}{\partial y}\right)^2 + f'\frac{\partial^2 u}{\partial y^2}$$

MULTIVARIABLE CALCULUS APPLIED TO THERMODYNAMICS

Many of the functional relationships needed in thermodynamics are direct applications of the rules of multivariable calculus. This section reviews those rules in the context of the needs of themodynamics. These ideas were expounded in one of the classic books on chemical engineering thermodynamics [see Hougen, O. A., et al., Part II, "Thermodynamics," in *Chemical Process Principles*, 2d ed., Wiley, New York (1959)].

State Functions State functions depend only on the state of the system, not on past history or how one got there. If z is a function of two variables, x and y, then $z(x,y)$ is a state function, since z is known once x and y are specified. The differential of z is

$$dz = M\,dx + N\,dy$$

The line integral

$$\int_C (M\,dx + N\,dy)$$

is independent of the path in x-y space if and only if

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x} \tag{3-42}$$

The total differential can be written as

$$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy \tag{3-43}$$

and the following condition guarantees path independence.

$$\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right)_y = \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right)_x$$

or
$$\frac{\partial^2 z}{\partial y\,\partial x} = \frac{\partial^2 z}{\partial x\,\partial y} \tag{3-44}$$

Example Suppose z is constant and apply Eq. (3-43).

$$\left[0 = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy\right]_z$$

Rearrangement gives

$$\left(\frac{\partial z}{\partial x}\right)_y = -\left(\frac{\partial y}{\partial x}\right)_z\left(\frac{\partial z}{\partial y}\right)_x = -\frac{(\partial y/\partial x)_z}{(\partial y/\partial z)_x} \tag{3-45}$$

Alternatively, divide Eq. (3-43) by dy when holding some other variable w constant to obtain

$$\left(\frac{\partial z}{\partial y}\right)_w = \left(\frac{\partial z}{\partial x}\right)_y\left(\frac{\partial x}{\partial y}\right)_w + \left(\frac{\partial z}{\partial y}\right)_x \tag{3-46}$$

Also divide both numerator and denominator of a partial derivative by dw while holding a variable y constant to get

$$\left(\frac{\partial z}{\partial x}\right)_y = \frac{(\partial z/\partial w)_y}{(\partial x/\partial w)_y} = \left(\frac{\partial z}{\partial w}\right)_y\left(\frac{\partial w}{\partial x}\right)_y \tag{3-47}$$

Themodynamic State Functions In thermodynamics, the state functions include the internal energy, U; enthalpy, H; and Helmholtz and Gibbs free energies, A and G, respectively, defined as follows:

$$H = U + pV$$
$$A = U - TS$$
$$G = H - TS = U + pV - TS = A + pV$$

S is the entropy, T the absolute temperature, p the pressure, and V the volume. These are also state functions, in that the entropy is specified once two variables (like T and p) are specified, for example. Likewise, V is specified once T and p are specified; it is therefore a state function.

All applications are for closed systems with constant mass. If a process is reversible and only p-V work is done, the first law and differentials can be expressed as follows.

$$dU = T\,dS - p\,dV$$
$$dH = T\,dS + V\,dp$$
$$dA = -S\,dT - p\,dV$$
$$dG = -S\,dT + V\,dp$$

Alternatively, if the internal energy is considered a function of S and V, then the differential is:

$$dU = \left(\frac{\partial U}{\partial S}\right)_V dS + \left(\frac{\partial U}{\partial V}\right)_S dV$$

This is the equivalent of Eq. (3-43) and gives the following definitions.

$$T = \left(\frac{\partial U}{\partial S}\right)_V, \quad p = -\left(\frac{\partial U}{\partial V}\right)_S$$

Since the internal energy is a state function, then Eq. (3-44) must be satisfied.

$$\frac{\partial^2 U}{\partial V\,\partial S} = \frac{\partial^2 U}{\partial S\,\partial V}$$

This is
$$\left(\frac{\partial T}{\partial V}\right)_S = -\left(\frac{\partial p}{\partial S}\right)_V$$

This is one of the Maxwell relations, and the other Maxwell relations can be derived in a similar fashion by applying Eq. (3-44).

See Sec. 4, Thermodynamics, "Constant-Composition Systems."

Partial Derivatives of All Thermodynamic Functions The various partial derivatives of the thermodynamic functions can be classified into six groups. In the general formulas below, the variables U, H, A, G or S are denoted by Greek letters, while the variables $V, T,$ or p are denoted by Latin letters.

Type I (3 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_c; \text{ Specific: } \left(\frac{\partial p}{\partial T}\right)_V$$

Eq. (3-45) gives

$$\left(\frac{\partial p}{\partial T}\right)_V = -\left(\frac{\partial V}{\partial T}\right)_p \left(\frac{\partial p}{\partial V}\right)_T = -\frac{(\partial V/\partial T)_p}{(\partial V/\partial p)_T}$$

Type II (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_c; \text{ Specific: } \left(\frac{\partial G}{\partial T}\right)_V$$

The differential for G gives

$$\left(\frac{\partial G}{\partial T}\right)_V = -S + V\left(\frac{\partial p}{\partial T}\right)_V$$

Using the other equations for $U, H, A,$ or S gives the other possibilities.

Type III (15 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_\alpha; \text{ Specific: } \left(\frac{\partial V}{\partial T}\right)_S$$

First expand the derivative using Eq. (3-45).

$$\left(\frac{\partial V}{\partial T}\right)_S = -\left(\frac{\partial S}{\partial T}\right)_V \left(\frac{\partial V}{\partial S}\right)_T = -\frac{(\partial S/\partial T)_V}{(\partial S/\partial V)_T}$$

Then evaluate the numerator and denominator as type II derivatives.

$$\left(\frac{\partial V}{\partial T}\right)_S = -\frac{\dfrac{C_V}{T}}{-\left(\dfrac{\partial V}{\partial T}\right)_p \left(\dfrac{\partial p}{\partial V}\right)_T} = \frac{C_V}{T}\frac{\left(\dfrac{\partial V}{\partial p}\right)_T}{\left(\dfrac{\partial V}{\partial T}\right)_p}$$

These derivatives are of importance for reversible, adiabatic processes (such as in an ideal turbine or compressor), since then the entropy is constant. An example is the Joule-Thomson coefficient for constant H.

$$\left(\frac{\partial T}{\partial p}\right)_H = \frac{1}{C_p}\left[-V + T\left(\frac{\partial V}{\partial T}\right)_p\right]$$

Type IV (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_c; \text{ Specific: } \left(\frac{\partial G}{\partial A}\right)_p$$

Use Eq. (3-47) to introduce a new variable.

$$\left(\frac{\partial G}{\partial A}\right)_p = \left(\frac{\partial G}{\partial T}\right)_p \left(\frac{\partial T}{\partial A}\right)_p = \frac{(\partial G/\partial T)_p}{(\partial A/\partial T)_p}$$

This operation has created two type II derivatives; by substitution we obtain

$$\left(\frac{\partial G}{\partial A}\right)_p = \frac{S}{S + p\,(\partial V/\partial T)_p}$$

Type V (60 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_\beta; \text{ Specific: } \left(\frac{\partial G}{\partial p}\right)_A$$

Start from the differential for dG. Then we get

$$\left(\frac{\partial G}{\partial p}\right)_A = -S\left(\frac{\partial T}{\partial p}\right)_A + V$$

The derivative is type III and can be evaluated by using Eq. (3-45).

$$\left(\frac{\partial G}{\partial p}\right)_A = S\frac{(\partial A/\partial p)_T}{(\partial A/\partial T)_p} + V$$

The two type II derivatives are then evaluated.

$$\left(\frac{\partial G}{\partial p}\right)_A = \frac{Sp\,(\partial V/\partial p)_T}{S + p\,(\partial V/\partial T)_p} + V$$

These derivatives are also of interest for free expansions or isentropic changes.

Type VI (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_\gamma; \text{ Specific: } \left(\frac{\partial G}{\partial A}\right)_H$$

We use Eq. (3-47) to obtain two type V derivatives.

$$\left(\frac{\partial G}{\partial A}\right)_H = \frac{(\partial G/\partial T)_H}{(\partial A/\partial T)_H}$$

These can then be evaluated using the procedures for Type V derivatives.

INTEGRAL CALCULUS

Indefinite Integral If $f'(x)$ is the derivative of $f(x)$, an antiderivative of $f'(x)$ is $f(x)$. Symbolically, the indefinite integral of $f'(x)$ is

$$\int f'(x)\,dx = f(x) + c$$

where c is an arbitrary constant to be determined by the problem. By virtue of the known formulas for differentiation the following relationships hold (a is a constant):

$$\int (du + dv + dw) = \int du + \int dv + \int dw \tag{3-48}$$

$$\int a\,dv = a\int dv \tag{3-49}$$

$$\int v^n\,dv = \frac{v^{n+1}}{n+1} + c \quad (n \neq -1) \tag{3-50}$$

$$\int \frac{dv}{v} = \ln|v| + c \tag{3-51}$$

$$\int a^v\,dv = \frac{a^v}{\ln a} + c \tag{3-52}$$

$$\int e^v\,dv = e^v + c \tag{3-53}$$

$$\int \sin v\,dv = -\cos v + c \tag{3-54}$$

$$\int \cos v\,dv = \sin v + c \tag{3-55}$$

$$\int \sec^2 v\,dv = \tan v + c \tag{3-56}$$

$$\int \csc^2 v\,dv = -\cot v + c \tag{3-57}$$

$$\int \sec v \tan v\,dv = \sec v + c \tag{3-58}$$

$$\int \csc v \cot v\,dv = -\csc v + c \tag{3-59}$$

$$\int \frac{dv}{v^2 + a^2} = \frac{1}{a}\tan^{-1}\frac{v}{a} + c \tag{3-60}$$

$$\int \frac{dv}{\sqrt{a^2 - v^2}} = \sin^{-1}\frac{v}{a} + c \tag{3-61}$$

$$\int \frac{dv}{v^2 - a^2} = \frac{1}{2a}\ln\left|\frac{v - a}{v + a}\right| + c \tag{3-62}$$

$$\int \frac{dv}{\sqrt{v^2 \pm a^2}} = \ln|v + \sqrt{v^2 \pm a^2}| + c \tag{3-63}$$

$$\int \sec v\,dv = \ln(\sec v + \tan v) + c \tag{3-64}$$

$$\int \csc v\, dv = \ln(\csc v - \cot v) + c \qquad (3\text{-}65)$$

Example Find $\int (3x^2 + e^x - 10)\, dx$ using Eq. (3-48). $\int (3x^2 + e^x - 10)\, dx = 3\int x^2\, dx + \int e^x\, dx - 10\int dx = x^3 + e^x - 10x + c$ (by Eqs. 3-50, 3-53).

Example Find $\int \frac{7x\, dx}{2 - 3x^2}$. Let $v = 2 - 3x^2$; $dv = -6x\, dx$

Thus
$$\int \frac{7x\, dx}{2-3x^2} = 7\int \frac{x\, dx}{2-3x^2} = -\frac{7}{6}\int \frac{-6x\, dx}{2-3x^2}$$

$$= -\frac{7}{6}\int \frac{dv}{v}, \text{ with } v = 2 - 3x^2 \text{ and } dv = -6x\, dx$$

$$= -\frac{7}{6}\ln|v| + c = -\frac{7}{6}\ln|2 - 3x^2| + c$$

Example—Constant of Integration By definition the derivative of x^3 is $3x^2$, and x^3 is therefore the integral of $3x^2$. However, if $f = x^3 + 10$, it follows that $f' = 3x^2$, and $x^3 + 10$ is therefore also the integral of $3x^2$. For this reason the constant c in $\int 3x^2\, dx = x^3 + c$ must be determined by the problem conditions, i.e., the value of f for a specified x.

Methods of Integration In practice it is rare when generally encountered functions can be directly integrated. For example, the integrand in $\int \sqrt{\sin x}\, dx$ which appears quite simple has no elementary function whose derivative is $\sqrt{\sin x}$. In general, there is no explicit way of determining whether a particular function can be integrated into an elementary form. As a whole, integration is a trial-and-error proposition which depends on the effort and ingenuity of the practitioner. The following are general procedures which can be used to find the elementary forms of the integral when they exist. When they do not exist or cannot be found either from tabled integration formulas or directly, the only recourse is series expansion as illustrated later. Indefinite integrals cannot be solved numerically unless they are redefined as definite integrals (see "Definite Integral"), i.e., $F(x) = \int f(x)\, dx$, indefinite, whereas $F(x) = \int_a^x f(t)\, dt$, definite.

Direct Formula Many integrals can be solved by transformation in the integrand to one of the forms given previously.

Example Find $\int x^2\sqrt{3x^3 + 10}\, dx$. Let $v = 3x^3 + 10$ for which $dv = 9x^2\, dx$. Thus

$$\int x^2\sqrt{3x^3+10}\, dx = \int (3x^3+10)^{1/2}(x^2\, dx)$$

$$= \frac{1}{9}\int (3x^3+10)^{1/2}(9x^2\, dx) = \frac{1}{9}\int v^{1/2}\, dv$$

$$= \frac{1}{9}\frac{v^{3/2}}{3/2} + c \qquad \text{[by Eq. (3-50)]}$$

$$= \frac{2}{27}(3x^3+10)^{3/2} + c$$

Trigonometric Substitution This technique is particularly well adapted to integrands in the form of radicals. For these the function is transformed into a trigonometric form. In the latter form they may be more easily recognizable relative to the identity formulas. These functions and their transformations are

$$\sqrt{x^2 - a^2} \quad \text{Let } x = a\sec\theta$$
$$\sqrt{x^2 + a^2} \quad \text{Let } x = a\tan\theta$$
$$\sqrt{a^2 - x^2} \quad \text{Let } x = a\sin\theta$$

Example Find $\int \frac{\sqrt{4-9x^2}}{x^2}\, dx$. Let $x = \frac{2}{3}\sin\theta$; then $dx = \frac{2}{3}\cos\theta\, d\theta$.

$$3\int \frac{\sqrt{(2/3)^2 - x^2}}{x^2}\, dx = 3\int \frac{2/3\sqrt{1-\sin^2\theta}}{(2/3)^2\sin^2\theta}\left(\frac{2}{3}\cos\theta\, d\theta\right)$$

$$= 3\int \frac{\cos^2\theta}{\sin^2\theta}\, d\theta = 3\int \cot^2\theta\, d\theta$$

$$= -3\cot\theta - 3\theta + c \text{ by trigonometric transform}$$

$$= -\frac{\sqrt{4-9x^2}}{x} - 3\sin^{-1}\frac{3}{2}x + c \text{ in terms of } x$$

Algebraic Substitution Functions containing elements of the type $(a + bx)^{1/n}$ are best handled by the algebraic transformation $y^n = a + bx$.

Example Find $\int \frac{x\, dx}{(3+4x)^{1/4}}$. Let $3 + 4x = y^4$; then $4dx = 4y^3\, dy$ and

$$\int \frac{x\, dx}{(3+4x)^{1/4}} = \int \frac{\frac{y^4-3}{4}y^3\, dy}{y} = \frac{1}{4}\int y^2(y^4-3)\, dy$$

$$= \frac{1}{4}\frac{y^7}{7} - \frac{3}{4}\frac{y^3}{3} + c = \frac{1}{28}(3+4x)^{7/4} - \frac{1}{4}(3+4x)^{3/4} + c$$

General The number of possible transformations one might use are unlimited. No specific overall rules can be given. Success in handling integration problems depends primarily upon experience and ingenuity. The following example illustrates the extent to which alternative approaches are possible.

Example Find $\int \frac{dx}{e^x - 1}$. Let $e^x = y$; then $e^x\, dx = dy$ or $dx = 1/y\, dy$.

$$\int \frac{dx}{e^x-1} = \int \frac{(1/y)\, dy}{y-1} = \int \frac{dy}{y^2-y} = \ln\frac{y-1}{y} = \ln\frac{e^x-1}{e^x}$$

Partial Fractions Rational functions are of the type $f(x)/g(x)$ where $f(x)$ and $g(x)$ are polynomial expressions of degrees m and n respectively. If the degree of f is higher than g, perform the algebraic division—the remainder will then be at least one degree less than the denominator. Consider the following types:

Type 1 Reducible denominator to linear unequal factors. For example,

$$\frac{1}{x^3 - x^2 - 4x + 4} = \frac{1}{(x+2)(x-2)(x-1)}$$

$$= \frac{A}{x+2} + \frac{B}{x-2} + \frac{C}{x-1}$$

$$= \frac{A(x-2)(x-1) + B(x+2)(x-1) + C(x+2)(x-2)}{(x+2)(x-2)(x-1)}$$

$$= \frac{x^2(A+B+C) + x(-3A+B) + (2A-2B-4C)}{(x+2)(x-2)(x-1)}$$

Equate coefficients and solve for A, B, and C.

$$A + B + C = 0$$
$$-3A + B = 0$$
$$2A - 2B - 4C = 1$$
$$A = 1/12,\ B = 1/4,\ C = -1/3$$

$$\frac{1}{x^3-x^2-4x+4} = \frac{1}{12(x+2)} + \frac{1}{4(x-2)} - \frac{1}{3(x-1)}$$

Hence

$$\int \frac{dx}{x^3-x^2-4x+4} = \int \frac{dx}{12(x+2)} + \int \frac{dx}{4(x-2)} - \int \frac{dx}{3(x-1)}$$

Parts An extremely useful formula for integration is the relation

$$d(uv) = u\, dv + v\, du$$

and
$$uv = \int u\, dv + \int v\, du$$

or
$$\int u\, dv = uv - \int v\, du$$

No general rule for breaking an integrand can be given. Experience alone limits the use of this technique. It is particularly useful for trigonometric and exponential functions.

Example Find $\int xe^x\, dx$. Let

$$u = x \qquad \text{and} \qquad dv = e^x\, dx$$
$$du = dx \qquad\qquad v = e^x$$

Therefore
$$\int xe^x\, dx = xe^x - \int e^x\, dx$$
$$= xe^x - e^x + c$$

Example Find $\int e^x \sin x\, dx$. Let

$$u = e^x \qquad dv = \sin x\, dx$$
$$du = e^x\, dx \qquad v = -\cos x$$
$$\int e^x \sin x\, dx = -e^x \cos x + \int e^x \cos x\, dx$$

Again
$$u = e^x \qquad dv = \cos x\, dx$$
$$du = e^x\, dx \qquad v = \sin x$$
$$\int e^x \sin x\, dx = -e^x \cos x + e^x \sin x - \int e^x \sin x\, dx + c$$
$$= (e^x/2)(\sin x - \cos x) + \frac{c}{2}$$

Series Expansion When an explicit function cannot be found, the integration can sometimes be carried out by a series expansion.

Example Find $\int e^{-x^2}\, dx$. Since

$$e^{-x^2} = 1 - x^2 + \frac{x^4}{2!} - \frac{x^6}{3!} + \cdots$$
$$\int e^{-x^2}\, dx = \int dx - \int x^2\, dx + \int \frac{x^4}{2!}\, dx - \int \frac{x^6}{3!}\, dx + \cdots$$
$$= x - \frac{x^3}{3} + \frac{x^5}{5.2!} - \frac{x^7}{7.3!} + \cdots \qquad \text{for all } x$$

Definite Integral The concept and derivation of the definite integral are completely different from those for the indefinite integral. These are by definition different types of operations. However, the formal operation $\int$ as it turns out treats the integrand in the same way for both.

Consider the function $f(x) = 10 - 10e^{-2x}$. Define $x_1 = a$ and $x_n = b$, and suppose it is desirable to compute the area between the curve and the coordinate axis $y = 0$ and bounded by $x_1 = a$, $x_n = b$. Obviously, by a sufficiently large number of rectangles this area could be approximated as closely as desired by the formula

$$\sum_{i=1}^{n-1} f(\xi_i)(x_{i+1} - x_i) = f(\xi_1)(x_2 - a) + f(\xi_2)(x_3 - x_2)$$
$$+ \cdots + f(\xi_{n-1})(b - x_{n-1}) \qquad x_{i-1} \le \xi_{i-1} \le x_i$$

The definite integral of $f(x)$ is defined as

$$\int_a^b f(x)\, dx = \lim_{n\to\infty} \sum_{i=1}^{n} f(\xi_i)(x_{i+1} - x_i)$$

where the points $x_1, x_2, \ldots, x_n$ are equally spaced.

Thus, the value of a definite integral depends on the limits a, b, and any selected variable coefficients in the function but not on the dummy variable of integration x. Symbolically

$$F(x) = \int f(x)\, dx \qquad \text{indefinite integral where } dF/dx = f(x)$$

or
$$F(a, b) = \int_a^b f(x)\, dx \qquad \text{definite integral}$$
$$F(\alpha) = \int_a^b f(x, \alpha)\, dx$$

There are certain restrictions of the integration definition, "The function $f(x)$ must be continuous in the finite interval (a, b) with at most a finite number of finite discontinuities," which must be observed before integration formulas can be generally applied. Relaxing two of these restrictions gives rise to so-called **improper integrals** and requires special handling. These occur when

1. The limits of integration are not both finite, i.e., $\int_0^\infty e^{-x}\, dx$.
2. The function becomes infinite within the interval of integration, i.e.,

$$\int_0^1 \frac{1}{\sqrt{x}}\, dx$$

Techniques for determining when integration is valid under these conditions are available in the references.

Properties The fundamental theorem of calculus states

$$\int_a^b f(x)\, dx = F(b) - F(a)$$

where
$$dF(x)/dx = f(x)$$

Other properties of the definite integral are

$$\int_a^b c[f(x)\, dx] = c\int_a^b f(x)\, dx$$
$$\int_a^b [f_1(x) + f_2(x)]\, dx = \int_a^b f_1(x)\, dx + \int_a^b f_2(x)\, dx$$
$$\int_a^b f(x)\, dx = -\int_b^a f(x)\, dx$$
$$\int_a^b f(x)\, dx = \int_a^c f(x)\, dx + \int_c^b f(x)\, dx$$
$$\int_a^b f(x)\, dx = (b - a)f(\xi) \text{ for some } \xi \text{ in } (a, b)$$
$$\frac{\partial}{\partial b}\int_a^b f(x)\, dx = f(b)$$
$$\frac{\partial}{\partial a}\int_a^b f(x)\, dx = -f(a)$$
$$\frac{dF(\alpha)}{d\alpha} = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha}\, dx \text{ if } a \text{ and } b \text{ are constant}$$
$$\int_a^b dx \int_c^d f(x, \alpha)\, d\alpha = \int_c^d d\alpha \int_a^b f(x, \alpha)\, dx \qquad (3\text{-}66)$$

When $F(x) = \int_{a(x)}^{b(x)} f(x, y)\, dy$, the Leibniz rule gives

$$\frac{dF}{dx} = \frac{db}{dx} f[x, b(x)] - \frac{da}{dx} f[x, a(x)] + \int_{a(x)}^{b(x)} \frac{\partial f}{\partial x}\, dy$$

Example Find $\int_0^2 \frac{dx}{(x-1)^2}$. Direct application of the formula would yield the incorrect value

$$\int_0^2 \frac{dx}{(x-1)^2} = \left[-\frac{1}{x-1}\right]_0^2 = -2$$

It should be noted that $f(x) = 1/(x - 1)^2$ becomes unbounded as $x \to 1$ and by Rule 2 the integral diverges and hence is said not to exist.

Methods of Integration All the methods of integration available for the indefinite integral can be used for definite integrals. In addition, several others are available for the latter integrals and are indicated below.

Change of Variable This substitution is basically the same as previously indicated for indefinite integrals. However, for definite integrals, the limits of integration must also be changed: i.e., for $x = \phi(t)$,

$$\int_a^b f(x)\, dx = \int_{t_0}^{t_1} f[\phi(t)]\phi'(t)\, dt$$

where $t = t_0$ when $x = a$
$t = t_1$ when $x = b$

Example Find $\int_0^4 \sqrt{16 - x^2}\,dx$. Let

$$x = 4 \sin\theta \qquad (x = 0, \theta = 0)$$
$$dx = 4\cos\theta\, d\theta \qquad (x = 4, \theta = \pi/2)$$

Then $$\int_0^4 \sqrt{16 - x^2}\,dx = 16\int_0^{\pi/2} \cos^2\theta\, d\theta = 16[\tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta]_0^{\pi/2} = 4\pi$$

Integration It is sometimes useful to generate a double integral to solve a problem. By this approach, the fundamental theorem indicated by Eq. (3-66) can be used.

Example Find $$\int_0^1 \frac{x^b - x^a}{\ln x}\,dx$$

Consider $$\int_0^1 x^\alpha\,dx = \frac{1}{\alpha + 1} \quad (\alpha > -1)$$

Then multiplying both sides by $d\alpha$ and integrating between a and b,

$$\int_a^b d\alpha \int_0^1 x^\alpha\,dx = \int_a^b \frac{d\alpha}{\alpha + 1} = \ln\left|\frac{b+1}{a+1}\right|$$

But also

$$\int_a^b d\alpha \int_0^1 x^\alpha\,dx = \int_0^1 dx \int_a^b x^\alpha\,d\alpha = \int_0^1 \frac{x^b - x^a}{\ln x}\,dx$$

Therefore $$\int_0^1 \frac{x^b - x^a}{\ln x}\,dx = \ln\left|\frac{b+1}{a+1}\right|$$

INFINITE SERIES

DEFINITIONS

A succession of numbers or terms that are formed according to some definite rule is called a sequence. The indicated sum of the terms of a sequence is called a series. A series of the form $a_0 + a_1(x - c) + a_2(x - c)^2 + \cdots + a_n(x - c)^n + \cdots$ is called a power series.

Consider the sum of a finite number of terms in the geometric series (a special case of a power series).

$$S_n = a + ar + ar^2 + ar^3 + \cdots + ar^{n-1} \tag{3-67}$$

For any number of terms n, the sum equals

$$S_n = a\,\frac{1 - r^n}{1 - r}$$

In this form, the geometric series is assumed finite.

In the form of Eq. (3-67), it can further be defined that the terms in the series be nonending and therefore an infinite series.

$$S = a + ar + ar^2 + \cdots + ar^n + \cdots \tag{3-68}$$

However, the defined sum of the terms [Eq. (3-67)]

$$S_n = a\,\frac{1 - r^n}{1 - r} \qquad r \neq 1$$

while valid for any finite value of r and n now takes on a different interpretation. In this sense it is necessary to consider the limit of S_n as n increases indefinitely:

$$S = \lim_{n\to\infty} S_n$$
$$= a \lim_{n\to\infty} \frac{1 - r^n}{1 - r}$$

For this, it is stated the infinite series converges if the limit of S_n approaches a fixed finite value as n approaches infinity. Otherwise, the series is **divergent.**

On this basis an analysis of

$$S = a \lim_{n\to\infty} \frac{1 - r^n}{1 - r}$$

shows that if r is less than 1 but greater than −1, the infinite series is convergent. For values outside of the range $-1 < r < 1$, the series is divergent because the sum is not defined. The range $-1 < r < 1$ is called the **region of convergence.** (We assume $a \neq 0$.)

There are also two types of convergent series. Consider the new series

$$S = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots + (-1)^{n+1}\frac{1}{n} + \cdots \tag{3-69}$$

It can be shown that the series (3-69) does converge to the value $S = \log 2$. However, if each term is replaced by its absolute value, the series becomes unbounded and therefore divergent (unbounded divergent):

$$S = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \cdots \tag{3-70}$$

In this case the series (3-69) is defined as a conditionally convergent series. If the replacement series of absolute values also converges, the series is defined to converge absolutely.

Series (3-69) is further defined as an alternating series, while series (3-70) is referred to as a positive series.

OPERATIONS WITH INFINITE SERIES

1. The convergence or divergence of an infinite series is unaffected by the removal of a finite number of finite terms. This is a trivial theorem but useful to remember, especially when using the comparison test to be described in the subsection "Tests for Convergence and Divergence."
2. If a series is conditionally convergent, its sums can be made to have any arbitrary value by a suitable rearrangement of the series; it can in fact be made divergent or oscillatory (Riemann's theorem).
3. A series of positive terms, if convergent, has a sum independent of the order of its terms; but if divergent, it remains divergent however its terms are rearranged.
4. An oscillatory series can always be made to converge by grouping terms.
5. A power series can be inverted, provided the first-degree term is not zero. Given

$$y = b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + \cdots$$

then $$x = B_1y + B_2y^2 + B_3y^3 + B_4y^4 + B_5y^5 + B_6y^6 + B_7y^7 + \cdots$$

where
$B_1 = 1/b_1$
$B_2 = -b_2/b_1^3$
$B_3 = (1/b_1^5)(2b_2^2 - b_1b_3)$
$B_4 = (1/b_1^7)(5b_1b_2b_3 - b_1^2b_4 - 5b_2^3)$

Additional coefficients are available in the references.

6. Two series may be added or subtracted term by term provided each is a convergent series. The joint sum is equal to the sum (or difference) of the individuals.

7. The sum of two divergent series can be convergent. Similarly, the sum of a convergent series and a divergent series must be divergent.

8. A power series may be integrated term by term to represent the integral of the function within an interval of the region of convergence. If $f(x) = a_0 + a_1x + a_2x^2 + \cdots$, then

$$\int_{x_1}^{x_2} f(x)\,dx = \int_{x_1}^{x_2} a_0\,dx + \int_{x_1}^{x_2} a_1x\,dx + \int_{x_1}^{x_2} a_2x^2\,dx + \cdots$$

9. A power series may be differentiated term by term and represents the function $df(x)/dx$ within the same region of convergence as $f(x)$.

TESTS FOR CONVERGENCE AND DIVERGENCE

In general, the problem of determining whether a given series will converge or not can require a great deal of ingenuity and resourcefulness. There is no all-inclusive test which can be applied to all series. As the only alternative, it is necessary to apply one or more of the developed theorems in an attempt to ascertain the convergence or divergence of the series under study. The following defined tests are given in relative order of effectiveness. For examples, see references on advanced calculus.

1. *Comparison Test.* A series will converge if the absolute value of each term (with or without a finite number of terms) is less than the corresponding term of a known convergent series. Similarly, a positive series is divergent if it is termwise larger than a known divergent series of positive terms.

2. *nth-Term Test.* A series is divergent if the nth term of the series does not approach zero as n becomes increasingly large.

3. *Ratio Test.* If the absolute ratio of the $(n + 1)$ term divided by the nth term as n becomes unbounded approaches
   a. A number less than 1, the series is absolutely convergent
   b. A number greater than 1, the series is divergent
   c. A number equal to 1, the test is inconclusive

4. *Alternating-Series Leibniz Test.* If the terms of a series are alternately positive and negative and never increase in value, the absolute series will converge, provided that the terms tend to zero as a limit.

5. *Cauchy's Root Test.* If the nth root of the absolute value of the nth term, as n becomes unbounded, approaches
   a. A number less than 1, the series is absolutely convergent
   b. A number greater than 1, the series is divergent
   c. A number equal to 1, the test is inconclusive

6. *Maclaurin's Integral Test.* Suppose $\sum a_n$ is a series of positive terms and f is a continuous decreasing function such that $f(x) \ge 0$ for $1 \le x < \infty$ and $f(n) = a_n$. Then the series and the improper integral $\int_1^\infty f(x)\,dx$ either both converge or both diverge.

SERIES SUMMATION AND IDENTITIES

Sums for the First *n* Numbers to Integer Powers

$$\sum_{j=1}^{n} j = \frac{n(n+1)}{2} = 1 + 2 + 3 + 4 + \cdots + n$$

$$\sum_{j=1}^{n} j^2 = \frac{n(n+1)(2n+1)}{6} = 1^2 + 2^2 + 3^2 + 4^2 + \cdots + n^2$$

$$\sum_{j=1}^{n} j^3 = \frac{n^2(n+1)^2}{4} = 1^3 + 2^3 + 3^3 + \cdots + n^3$$

Arithmetic Progression

$$\sum_{k=1}^{n} [a + (k-1)d] = a + (a + d) + (a + 2d) + (a + 3d) + \cdots + [a + (n-1)]d$$
$$= na + \frac{1}{2}n(n-1)d$$

Geometric Progression

$$\sum_{j=1}^{n} ar^{j-1} = a + ar + ar^2 + ar^3 + \cdots + ar^{n-1} = a\,\frac{1-r^n}{1-r} \qquad r \ne 1$$

Harmonic Progression

$$\sum_{k=0}^{n} \frac{1}{a+kd} = \frac{1}{a} + \frac{1}{a+d} + \frac{1}{a+2d} + \frac{1}{a+3d} + \frac{1}{a+4d} + \cdots + \frac{1}{a+nd}$$

The reciprocals of the terms of the arithmetic-progression series are called harmonic progression. No general summation formulas are available for this series.

Binomial Series (see also Elementary Algebra)

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)}{2!}x^2 \pm \frac{n(n-1)(n-2)}{3!}x^3 + \cdots \quad (x^2 < 1)$$

Taylor's Series

$$f(h + x) = f(h) + xf'(h) + \frac{x^2}{2!}f''(h) + \frac{x^3}{3!}f'''(h) + \cdots$$

or $$f(x) = f(x_0) + f'(x_0)(x - x_0) + \frac{f''(x_0)}{2!}(x - x_0)^2 + \frac{f'''(x_0)}{3!}(x - x_0)^3 + \cdots$$

Example Find a series expansion for $f(x) = \ln(1 + x)$ about $x_0 = 0$.

$$f'(x) = (1 + x)^{-1}, \quad f''(x) = -(1 + x)^{-2}, \quad f'''(x) = 2(1 + x)^{-3}, \text{ etc.}$$

thus $$f(0) = 0, \quad f'(0) = 1, \quad f''(0) = -1, \quad f'''(1) = 2, \text{ etc.}$$

$$\ln(x + 1) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots + (-1)^{n+1}\frac{x^n}{n} + \cdots$$

which converges for $-1 < x \le 1$.

Maclaurin's Series

$$f(x) = f(0) + xf'(0) + \frac{x^2}{2!}f''(0) + \frac{x^3}{3!}f'''(0) + \cdots$$

This is simply a special case of Taylor's series when h is set to zero.

Exponential Series

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} + \cdots -\infty < x < \infty$$

Logarithmic Series

$$\ln x = \frac{x-1}{x} + \frac{1}{2}\left(\frac{x-1}{x}\right)^2 + \frac{1}{3}\left(\frac{x-1}{x}\right)^3 + \cdots \qquad (x > ½)$$

$$\ln x = 2\left[\left(\frac{x-1}{x+1}\right) + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3 + \cdots \quad (x > 0)\right.$$

Trigonometric Series*

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots \qquad -\infty < x < \infty$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots \qquad -\infty < x < \infty$$

$$\sin^{-1} x = x + \frac{x^3}{6} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{x^5}{5} + \frac{1}{2}\cdot\frac{3}{4}\cdot\frac{5}{6}\cdot\frac{x^7}{7} + \cdots \qquad (x^2 < 1)$$

$$\tan^{-1} x = x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \cdots \qquad (x^2 < 1)$$

Taylor Series The Taylor series for a function of two variables, expanded about the point (x_0, y_0), is

* tan x series has awkward coefficients and should be computed as $\left[(\text{sign})\dfrac{\sin x}{\sqrt{1 - \sin^2 x}}\right]$.

$$f(x, y) = f(x_0, y_0) + \left.\frac{\partial f}{\partial x}\right|_{x_0, y_0}(x - x_0) + \left.\frac{\partial f}{\partial y}\right|_{x_0, y_0}(y - y_0)$$
$$+ \frac{1}{2!}\left[\left.\frac{\partial^2 f}{\partial x^2}\right|_{x_0, y_0}(x - x_0)^2 + 2\left.\frac{\partial^2 f}{\partial x \partial y}\right|_{x_0, y_0}(x - x_0)(y - y_0) + \left.\frac{\partial^2 f}{\partial y^2}\right|_{x_0, y_0}(y - y_0)^2\right] + \cdots$$

Partial Sums of Infinite Series, and How They Grow Calculus textbooks devote much space to tests for convergence and divergence of series that are of little practical value, since a convergent series either converges rapidly, in which case almost any test (among those presented in the preceding subsections) will do; or it converges slowly, in which case it is not going to be of much use unless there is some way to get at its sum without adding up an unreasonable number of terms. To find out, as accurately as possible, how fast a convergent series converges and how fast a divergent series diverges, see Boas, R. P., Jr., *Am. Math. Mon.* **84:** 237–258 (1977).

COMPLEX VARIABLES

References: Ablowitz, M. J., and A. S. Fokas, *Complex Variables: Introduction and Applications,* Cambridge University Press, New York (2003); Asmar, N., and G. C. Jones, *Applied Complex Analysis with Partial Differential Equations,* Prentice-Hall, Upper Saddle River, N.J. (2002); Brown, J. W., and R. V. Churchill, *Complex Variables and Applications,* 7th ed., McGraw-Hill, New York (2003); Kaplan, W., *Advanced Calculus,* 5th ed., Addison-Wesley, Redwood City, Calif. (2003); Kwok, Y. K., *Applied Complex Variables for Scientists and Engineers,* Cambridge University Press, New York (2002); McGehee, O. C., *An Introduction to Complex Analysis,* Wiley, New York (2000); Priestley, H. A., *Introduction to Complex Analysis,* Oxford University Press, New York (2003).

Numbers of the form $z = x + iy$, where x and y are real, $i^2 = -1$, are called complex numbers. The numbers $z = x + iy$ are representable in the plane as shown in Fig. 3-45. The following definitions and terminology are used:

1. Distance $OP = r$ = modulus of z written $|z|$. $|z| = \sqrt{x^2 + y^2}$.
2. x is the real part of z.
3. y is the imaginary part of z.
4. The angle θ, $0 \le \theta < 2\pi$, measured counterclockwise from the positive x axis to OP is the argument of z. $\theta = \arctan y/x = \arcsin y/r = \arccos x/r$ if $x \neq 0$, $\theta = \pi/2$ if $x = 0$ and $y > 0$.
5. The numbers r, θ are the polar coordinates of z.
6. $\bar{z} = x - iy$ is the complex conjugate of z.

ALGEBRA

Let $z_1 = x_1 + iy_1$, $z_2 = x_2 + iy_2$.

Equality $z_1 = z_2$ if and only if $x_1 = x_2$ and $y_1 = y_2$.

Addition $z_1 + z_2 = (x_1 + x_2) + i(y_1 + y_2)$.

Subtraction $z_1 - z_2 = (x_1 - x_2) + i(y_1 - y_2)$.

Multiplication $z_1 \cdot z_2 = (x_1x_2 - y_1y_2) + i(x_1y_2 + x_2y_1)$.

Division $z_1/z_2 = \dfrac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2} + i\dfrac{x_2y_1 - x_1y_2}{x_2^2 + y_2^2}$, $z_2 \neq 0$.

SPECIAL OPERATIONS

$z\bar{z} = x^2 + y^2 = |z|^2$; $\overline{z_1 \pm z_2} = \bar{z}_1 \pm \bar{z}_2$; $\bar{\bar{z}}_1 = z_1$; $\overline{z_1 z_2} = \bar{z}_1\bar{z}_2$; $|z_1 \cdot z_2| = |z_1| \cdot |z_2|$; $\arg(z_1 \cdot z_2) = \arg z_1 + \arg z_2$; $\arg(z_1/z_2) = \arg z_1 - \arg z_2$; $i^{4n} = 1$ for n any integer; $i^{2n} = -1$ where n is any odd integer; $z + \bar{z} = 2x$; $z - \bar{z} = 2iy$.

Every complex quantity can be expressed in the form $x + iy$.

TRIGONOMETRIC REPRESENTATION

By referring to Fig. 3-45, there results $x = r\cos\theta$, $y = r\sin\theta$ so that $z = x + iy = r(\cos\theta + i\sin\theta)$, which is called the polar form of the complex number. $\cos\theta + i\sin\theta = e^{i\theta}$. Hence $z = x + iy = re^{i\theta}$. $\bar{z} = x - iy = re^{-i\theta}$. Two important results from this are $\cos\theta = (e^{i\theta} + e^{-i\theta})/2$ and $\sin\theta = (e^{i\theta} - e^{-i\theta})/2i$. Let $z_1 = r_1e^{i\theta_1}$, $z_2 = r_2e^{i\theta_2}$. This form is convenient for multiplication for $z_1z_2 = r_1r_2e^{i(\theta_1+\theta_2)}$ and for division for $z_1/z_2 = (r_1/r_2)e^{i(\theta_1-\theta_2)}$, $z_2 \neq 0$.

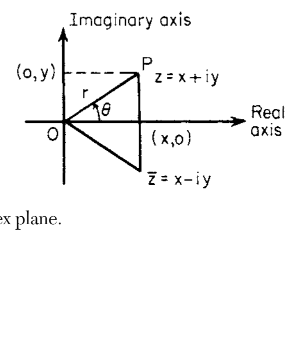

FIG. 3-45 Complex plane.

POWERS AND ROOTS

If n is a positive integer, $z^n = (re^{i\theta})^n = r^n e^{in\theta} = r^n(\cos n\theta + i\sin n\theta)$.

If n is a positive integer,

$$z^{1/n} = r^{1/n}e^{i[(\theta+2k\pi)/n]} = r^{1/n}\left[\cos\left(\frac{\theta + 2k\pi}{n}\right) + i\sin\left(\frac{\theta + 2k\pi}{n}\right)\right]$$

and selecting values of $k = 0, 1, 2, 3, \ldots, n - 1$ give the n distinct values of $z^{1/n}$. The n roots of a complex quantity are uniformly spaced around a circle, with radius $r^{1/n}$, in the complex plane in a symmetric fashion.

Example Find the three cube roots of −8. Here $r = 8$, $\theta = \pi$. The roots are $z_0 = 2(\cos\pi/3 + i\sin\pi/3) = 1 + i\sqrt{3}$, $z_1 = 2(\cos\pi + i\sin\pi) = -2$, $z_2 = 2(\cos 5\pi/3 + i\sin 5\pi/3) = 1 - i\sqrt{3}$.

ELEMENTARY COMPLEX FUNCTIONS

Polynomials A polynomial in z, $a_nz^n + a_{n-1}z^{n-1} + \cdots + a_0$, where n is a positive integer, is simply a sum of complex numbers times integral powers of z which have already been defined. Every polynomial of degree n has precisely n complex roots provided each multiple root of multiplicity m is counted m times.

Exponential Functions The exponential function e^z is defined by the equation $e^z = e^{x+iy} = e^x \cdot e^{iy} = e^x(\cos y + i\sin y)$. Properties: $e^0 = 1$; $e^{z_1} \cdot e^{z_2} = e^{z_1+z_2}$; $e^{z_1}/e^{z_2} = e^{z_1-z_2}$; $e^{z+2k\pi i} = e^z$.

Trigonometric Functions $\sin z = (e^{iz} - e^{-iz})/2i$; $\cos z = (e^{iz} + e^{-iz})/2$; $\tan z = \sin z/\cos z$; $\cot z = \cos z/\sin z$; $\sec z = 1/\cos z$; $\csc z = 1/\sin z$. Fundamental identities for these functions are the same as their real counterparts. Thus $\cos^2 z + \sin^2 z = 1$, $\cos(z_1 \pm z_2) = \cos z_1 \cos z_2 \mp \sin z_1 \sin z_2$, $\sin(z_1 \pm z_2) = \sin z_1 \cos z_2 \pm \cos z_1 \sin z_2$. The sine and cosine of z are periodic functions of period 2π; thus $\sin(z + 2\pi) = \sin z$. For computation purposes $\sin z = \sin(x + iy) = \sin x \cosh y + i\cos x \sinh y$, where $\sin x$, $\cosh y$, etc., are the real trigonometric and hyperbolic functions. Similarly, $\cos z = \cos x \cosh y - i\sin x \sinh y$. If $x = 0$ in the results given, $\cos iy = \cosh y$, $\sin iy = i\sinh y$.

Example Find all solutions of $\sin z = 3$. From previous data $\sin z = \sin x \cosh y + i\cos x \sinh y = 3$. Equating real and imaginary parts $\sin x \cosh y = 3$, $\cos x \sinh y = 0$. The second equation can hold for $y = 0$ or for $x = \pi/2, 3\pi/2, \ldots$. If $y = 0$, $\cosh 0 = 1$ and $\sin x = 3$ is impossible for real x. Therefore, $x = \pm\pi/2, \pm 3\pi/2, \ldots \pm(2n + 1)\pi/2$, $n = 0, \pm 1, \pm 2, \ldots$. However, $\sin 3\pi/2 = -1$ and $\cosh y \ge 1$. Hence $x = \pi/2, 5\pi/2, \ldots$. The solution is $z = [(4n + 1)\pi]/2 + i\cosh^{-1} 3$, $n = 0, 1, 2, 3, \ldots$.

Example Find all solutions of $e^z = -i$. $e^z = e^x(\cos y + i\sin y) = -i$. Equating real and imaginary parts gives $e^x \cos y = 0$, $e^x \sin y = -1$. From the first $y = \pm\pi/2, \pm 3\pi/2, \ldots$. But $e^x > 0$. Therefore, $y = 3\pi/2, 7\pi/2, -\pi/2, \ldots$. Then $x = 0$. The solution is $z = i[(4n + 3)\pi]/2$.

Two important facets of these functions should be recognized. First, the $\sin z$ is *unbounded;* and, second, e^z takes *all* complex values *except* 0.

Hyperbolic Functions $\sinh z = (e^z - e^{-z})/2$; $\cosh z = (e^z + e^{-z})/2$; $\tanh z = \sinh z/\cosh z$; $\coth z = \cosh z/\sinh z$; $\text{csch } z = 1/\sinh z$; $\text{sech } z = 1/\cosh z$. Identities are: $\cosh^2 z - \sinh^2 z = 1$; $\sinh (z_1 + z_2) = \sinh z_1 \cosh z_2 + \cosh z_1 \sinh z_2$; $\cosh (z_1 + z_2) = \cosh z_1 \cosh z_2 + \sinh z_1 \sinh z_2$; $\cosh z + \sinh z = e^z$; $\cosh z - \sinh z = e^{-z}$. The hyperbolic sine and hyperbolic cosine are periodic functions with the imaginary period $2\pi i$. That is, $\sinh (z + 2\pi i) = \sinh z$.

Logarithms The logarithm of z, $\log z = \log |z| + i(\theta + 2n\pi)$, where $\log |z|$ is taken to the base e and θ is the principal argument of z, that is, the particular argument lying in the interval $0 \le \theta < 2\pi$. The logarithm of z is infinitely many valued. If $n = 0$, the resulting logarithm is called the principal value. The familiar laws $\log z_1z_2 = \log z_1 + \log z_2$, $\log z_1/z_2 = \log z_1 - \log z_2$, $\log z^n = n \log z$ hold for the principal value.

General powers of z are defined by $z^\alpha = e^{\alpha \log z}$. Since $\log z$ is infinitely many valued, so too is z^α unless α is a rational number.

DeMoivre's formula can be derived from properties of e^z.

$$z^n = r^n (\cos \theta + i \sin \theta)^n = r^n (\cos n\theta + i \sin n\theta)$$

Thus

$$(\cos \theta + i \sin \theta)^n = \cos n\theta + i \sin n\theta$$

COMPLEX FUNCTIONS (ANALYTIC)

In the real-number system a greater than $b(a > b)$ and b less than $c(b < c)$ define an order relation. These relations have no meaning for complex numbers. The absolute value is used for ordering. Some important relations follow: $|z| \ge x$; $|z| \ge y$; $|z_1 \pm z_2| \le |z_1| + |z_2|$; $|z_1 - z_2| \ge ||z_1| - |z_2||$; $|z| \ge (|x| + |y|)/\sqrt{2}$. Parts of the complex plane, commonly called **regions** or **domains,** are described by using inequalities.

Example $|z - 3| \le 5$. This is equivalent to $\sqrt{(x-3)^2 + y^2} \le 5$, which is the set of all points within and on the circle, centered at $x = 3$, $y = 0$ of radius 5.

Example $|z - 1| \le x$ represents the set of all points inside and on the parabola $2x = y^2 + 1$ or, equivalently, $2x \ge y^2 + 1$.

Functions of a Complex Variable If $z = x + iy$, $w = u + iv$ and if for each value of z in some region of the complex plane one or more values of w are defined, then w is said to be a function of z, $w = f(z)$. Some of these functions have already been discussed, e.g., $\sin z$, $\log z$. All functions are reducible to the form $w = u(x, y) + iv(x, y)$, where u, v are real functions of the real variables x and y.

Example $z^3 = (x + iy)^3 = x^3 + 3x^2(iy) + 3x(iy)^2 + (iy)^3 = (x^3 - 3xy^2) + i(3x^2y - y^3)$.

Differentiation The *derivative* of $w = f(z)$ is

$$\frac{dw}{dz} = \lim_{\Delta z \to 0} \frac{f(z + \Delta z) - f(z)}{\Delta z}$$

and for the derivative to exist the limit must be the same no matter how Δz approaches zero. If w_1, w_2 are differentiable functions of z, the following rules apply:

$$\frac{d(w_1 \pm w_2)}{dz} = \frac{dw_1}{dz} \pm \frac{dw_2}{dz} \qquad \frac{d(w_1w_2)}{dz} = w_2\frac{dw_1}{dz} + w_1\frac{dw_2}{dz}$$

$$\frac{d(w_1/w_2)}{dz} = \frac{w_2(dw_1/dz) - w_1(dw_2/dz)}{w_2^2}$$

and

$$\frac{dw_1^n}{dz} = nw_1^{n-1}\frac{dw_1}{dz}$$

For $w = f(z)$ to be differentiable, it is necessary that $\partial u/\partial x = \partial v/\partial y$ and $\partial v/\partial x = -\partial u/\partial y$. The last two equations are called the Cauchy-Riemann equations. The derivative

$$\frac{dw}{dz} = \frac{\partial u}{\partial x} + i\frac{\partial v}{\partial x} = \frac{\partial v}{\partial y} - i\frac{\partial u}{\partial y}$$

If $f(z)$ possesses a derivative at z_o and at every point in some neighborhood of z_0, then $f(z)$ is said to be analytic or homomorphic at z_0. If the Cauchy-Riemann equations are satisfied and

$$u,\ v,\ \frac{\partial u}{\partial x}, \frac{\partial u}{\partial y}, \frac{\partial v}{\partial x}, \frac{\partial v}{\partial y}$$

are continuous in a region of the complex plane, then $f(z)$ is analytic in that region.

Example $w = z\bar{z} = x^2 + y^2$. Here $u = x^2 + y^2$, $v = 0$. $\partial u/\partial x = 2x$, $\partial u/\partial y = 2y$, $\partial v/\partial x = \partial v/\partial y = 0$. These are continuous everywhere, but the Cauchy-Riemann equations hold only at the origin. Therefore, w is nowhere analytic, but it is differentiable at $z = 0$ only.

Example $w = e^z = e^x \cos y + ie^x \sin y$. $u = e^x \cos y$, $v = e^x \sin y$. $\partial u/\partial x = e^x \cos y$, $\partial u/\partial y = -e^x \sin y$, $\partial v/\partial x = e^x \sin y$, $\partial v/\partial y = e^x \cos y$. The continuity and Cauchy-Riemann requirements are satisfied for all finite z. Hence e^z is analytic (except at ∞) and $dw/\partial z = \partial u/\partial x + i(\partial v/\partial x) = e^z$.

Example $w = \dfrac{1}{z} = \dfrac{x - iy}{x^2 + y^2} = \dfrac{x}{x^2 + y^2} - i\dfrac{y}{x^2 + y^2}$

It is easy to see that dw/dz exists except at $z = 0$. Thus $1/z$ is analytic except at $z = 0$.

Singular Points If $f(z)$ is analytic in a region except at certain points, those points are called singular points.

Example $1/z$ has a singular point at zero.

Example $\tan z$ has singular points at $z = \pm(2n + 1)(\pi/2)$, $n = 0, 1, 2, \ldots$.

The derivatives of the common functions, given earlier, are the same as their real counterparts.

Example $(d/dz)(\log z) = 1/z$, $(d/dz)(\sin z) = \cos z$.

Harmonic Functions Both the *real* and the *imaginary* parts of any analytic function $f = u + iv$ satisfy Laplace's equation $\partial^2\phi/\partial x^2 + \partial^2\phi/\partial y^2 = 0$. A function which possesses continuous second partial derivatives and satisfies Laplace's equation is called a harmonic function.

Example $e^z = e^x \cos y + ie^x \sin y$. $u = e^x \cos y$, $\partial u/\partial x = e^x \cos y$, $\partial^2u/\partial x^2 = e^x \cos y$, $\partial u/\partial y = -e^x \sin y$, $\partial^2u/\partial y^2 = -e^x \cos y$. Clearly $\partial^2u/\partial x^2 + \partial^2u/\partial y^2 = 0$. Similarly, $v = e^x \sin y$ is also harmonic.

If $w = u + iv$ is analytic, the curves $u(x, y) = c$ and $v(x, y) = k$ intersect at right angles, if $w^i(z) \neq 0$.

Integration In much of the work with complex variables a simple extension of integration called line or curvilinear integration is of fundamental importance. Since any complex line integral can be expressed in terms of real line integrals, we define only real line integrals. Let $F(x,y)$ be a real, continuous function of x and y and c be any continuous curve of finite length joining the points A and B (Fig. 3-46). $F(x,y)$ is not related to the curve c. Divide c up into n segments, Δs_i, whose projection on the x axis is Δx_i and on the y axis is Δy_i. Let (ε_i, η_i) be the coordinates of an arbitrary point on Δs_i. The limits of the sums

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\, \Delta s_i = \int_c F(x, y)\, ds$$

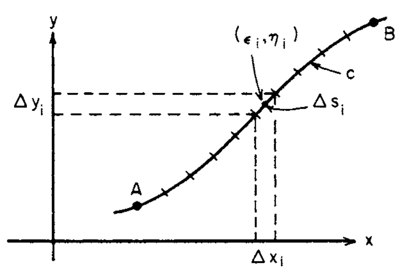

FIG. 3-46 Line integral.

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\, \Delta x_i = \int_c F(x, y)\, dx$$

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\, \Delta y_i = \int_c F(x, y)\, dy$$

are known as line integrals. Much of the initial strangeness of these integrals will vanish if it be observed that the ordinary definite integral $\int_a^b f(x)\,dx$ is just a line integral in which the curve c is a line segment on the x axis and $F(x, y)$ is a function of x alone. The evaluation of line integrals can be reduced to evaluation of ordinary integrals.

Example $\int_c y(1+x)\,dy$, where c: $y = 1 - x^2$ from $(-1, 0)$ to $(1, 0)$. Clearly $y = 1 - x^2$, $dy = -2x\,dx$. Thus $\int_c y(1+x)\,dy = -2\int_{-1}^{1} (1-x^2)(1+x)x\,dx = -8/15$.

Example $\int_c x^2 y\,ds$, c is the square whose vertices are $(0, 0)$, $(1, 0)$, $(1, 1)$, $(0, 1)$. $ds = \sqrt{dx^2 + dy^2}$. When $dx = 0$, $ds = dy$. From $(0, 0)$ to $(1, 0)$, $y = 0$, $dy = 0$. Similar arguments for the other sides give

$$\int_c x^2 y\,ds = \int_0^1 0.x^2\,dx + \int_0^1 y\,dy + \int_1^0 x^2\,dx + \int_1^0 0.y\,dy = 1/2 - 1/3 = 1/6$$

Let $f(z)$ be any function of z, analytic or not, and c any curve as above. The complex integral is calculated as $\int_c f(z)\,dz = \int_c (u\,dx - v\,dy) + i\int_c (v\,dx + u\,dy)$, where $f(z) = u(x, y) + iv(x, y)$. Properties of line integrals are the same as those for ordinary integrals. That is, $\int_c [f(z) \pm g(z)]\,dz = \int_c f(z)\,dz \pm \int_c g(z)\,dz$; $\int_c kf(z)\,dz = k\int_c f(z)\,dz$ for any constant k, etc.

Example $\int_c (x^2 + iy)\,dz$ along c: $y = x$, 0 to $1 + i$. This becomes

$$\int_c (x^2 + iy)\,dz = \int_c (x^2\,dx - y\,dy)$$

$$+ i\int_c (y\,dx + x^2\,dy) = \int_0^1 x^2\,dx - \int_0^1 x\,dx + i\int_0^1 x\,dx + i\int_0^1 x^2\,dx = -1/6 + 5i/6$$

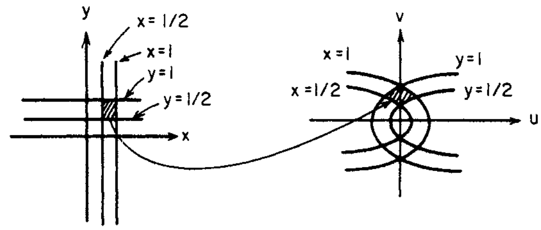

FIG. 3-47 Conformal transformation.

Conformal Mapping Every function of a complex variable $w = f(z) = u(x, y) + iv(x, y)$ transforms the x, y plane into the u, v plane in some manner. A conformal transformation is one in which angles between curves are preserved in *magnitude* and *sense.* Every analytic function, except at those points where $f'(z) = 0$, is a conformal transformation. See Fig. 3-47.

Example $w = z^2$. $u + iv = (x^2 - y^2) + 2ixy$ or $u = x^2 - y^2$, $v = 2xy$. These are the transformation equations between the (x, y) and (u, v) planes. Lines parallel to the x axis, $y = c_1$ map into curves in the u, v plane with parametric equations $u = x^2 - c_1^2$, $v = 2c_1 x$. Eliminating x, $u = (v^2/4c_1^2) - c_1^2$, which represents a family of parabolas with the origin of the w plane as focus, the line $v = 0$ as axis and opening to the right. Similar arguments apply to $x = c_2$.

The principles of complex variables are useful in the solution of a variety of applied problems, including Laplace transforms and process control (Sec. 8).

DIFFERENTIAL EQUATIONS

The natural laws in any scientific or technological field are not regarded as precise and definitive until they have been expressed in mathematical form. Such a form, often an equation, is a relation between the quantity of interest, say, product yield, and independent variables such as time and temperature upon which yield depends. When it happens that this equation involves, besides the function itself, one or more of its derivatives it is called a differential equation.

Example The rate of the homogeneous bimolecular reaction $A + B \xrightarrow{k} C$ is characterized by the differential equation $dx/dt = k(a - x)(b - x)$, where a = initial concentration of A, b = initial concentration of B, and $x = x(t)$ = concentration of C as a function of time t.

Example The differential equation of heat conduction in a moving fluid with velocity components v_x, v_y is

$$\frac{\partial u}{\partial t} + v_x \frac{\partial u}{\partial x} + v_y \frac{\partial u}{\partial y} = \frac{K}{\rho c_p}\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right)$$

where $u = u(x, y, t)$ = temperature, K = thermal conductivity, ρ = density, and c_p = specific heat at constant pressure.

ORDINARY DIFFERENTIAL EQUATIONS

When the function involved in the equation depends upon only one variable, its derivatives are ordinary derivatives and the differential equation is called an ordinary differential equation. When the function depends upon several independent variables, then the equation is called a partial differential equation. The theories of ordinary and partial differential equations are quite different. In almost every respect the latter is more difficult.

Whichever the type, a differential equation is said to be of nth order if it involves derivatives of order n but no higher. The equation in the first example is of first order and that in the second example of second order. The degree of a differential equation is the power to which the derivative of the highest order is raised after the equation has been cleared of fractions and radicals in the dependent variable and its derivatives.

A relation between the variables, involving no derivatives, is called a solution of the differential equation if this relation, when substituted in the equation, satisfies the equation. A solution of an ordinary differential equation which includes the maximum possible number of "arbitrary" constants is called the **general solution.** The maximum number of "arbitrary" constants is exactly equal to the order of the

differential equation. If any set of specific values of the constants is chosen, the result is called a **particular solution.**

Example The general solution of $(d^2x/dt^2) + k^2x = 0$ is $x = A \cos kt + B \sin kt$, where A, B are arbitrary constants. A particular solution is $x = \frac{1}{2} \cos kt + 3 \sin kt$.

In the case of some equations still other solutions exist called singular solutions. A **singular solution** *is any solution of the differential equation which is not included in the general solution.*

Example $y = x(dy/dx) - \frac{1}{4}(dy/dx)^2$ has the general solution $y = cx - \frac{1}{4}c^2$, where c is an arbitrary constant; $y = x^2$ is a singular solution, as is easily verified.

ORDINARY DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

Equations with Separable Variables Every differential equation of the first order and of the first degree can be written in the form $M(x, y)\, dx + N(x, y)\, dy = 0$. If the equation can be transformed so that M does not involve y and N does not involve x, then the variables are said to be separated. The solution can then be obtained by **quadrature,** which means that $y = \int f(x)\, dx + c$, which may or may not be expressible in simpler form.

Example Two liquids A and B are boiling together in a vessel. Experimentally it is found that the ratio of the rates at which A and B are evaporating at any time is proportional to the ratio of the amount of A (say, x) to the amount of B (say, y) still in the liquid state. This physical law is expressible as $(dy/dt)/(dx/dt) = ky/x$ or $dy/dx = ky/x$, where k is a proportionality constant. This equation may be written $dy/y = k(dx/x)$, in which the variables are separated. The solution is $\ln y = k \ln x + \ln c$ or $y = cx^k$.

Exact Equations The equation $M(x, y)\, dx + N(x, y)\, dy = 0$ is exact if and only if $\partial M/\partial y = \partial N/\partial x$. In this case there exists a function $w = f(x, y)$ such that $\partial f/\partial x = M$, $\partial f/\partial y = N$, and $f(x, y) = C$ is the required solution. $f(x, y)$ is found as follows: treat y as though it were constant and evaluate $\int M(x, y)\, dx$. Then treat x as though it were constant and evaluate $\int N(x, y)\, dy$. The sum of all unlike terms in these two integrals (including no repetitions) is $f(x, y)$.

Example $(2xy - \cos x)\, dx + (x^2 - 1)\, dy = 0$ is exact for $\partial M/\partial y = 2x$, $\partial N/\partial x = 2x$. $\int M\, dx = \int (2xy - \cos x)\, dx = x^2y - \sin x$, $\int N\, dy = \int (x^2 - 1)\, dy = x^2y - y$. The solution is $x^2y - \sin x - y = C$, as may easily be verified.

Linear Equations A differential equation is said to be linear when it is of first degree in the dependent variable and its derivatives. The general linear first-order differential equation has the form $dy/dx + P(x)y = Q(x)$. Its general solution is

$$y = e^{-\int P\, dx} \left[\int Q e^{\int P\, dx}\, dx + C \right]$$

Example A tank initially holds 200 gal of a salt solution in which 100 lb is dissolved. Six gallons of brine containing 4 lb of salt run into the tank per minute. If mixing is perfect and the output rate is 4 gal/min, what is the amount A of salt in the tank at time t? The differential equation of A is $dA/dt = [2/(100 + t)]A = 4$. Its general solution is $A = (4/3)\,(100 + t) + C/(100 + t)^2$. At $t = 0$, $'A = 100$; so the particular solution is $A = (4/3)\,(100 + t) - (1/3)\, 10^6/(100 + t)^2$.

ORDINARY DIFFERENTIAL EQUATIONS OF HIGHER ORDER

The higher-order differential equations, especially those of order 2, are of great importance because of physical situations describable by them.

Equation $y^{(n)} = f(x)$* Such a differential equation can be solved by n integrations. The solution will contain n arbitrary constants.

Linear Differential Equations with Constant Coefficients and Right-Hand Member Zero (Homogeneous) The solution of $y'' + ay' + by = 0$ depends upon the nature of the roots of the characteristic equation $m^2 + am + b = 0$ obtained by substituting the trial solution $y = e^{mx}$ in the equation.

*The superscript (n) means n derivatives.

Distinct Real Roots If the roots of the characteristic equation are distinct real roots, r_1 and r_2, say, the solution is $y = Ae^{r_1x} + Be^{r_2x}$, where A and B are arbitrary constants.

Example $y'' + 4y' + 3 = 0$. The characteristic equation is $m^2 + 4m + 3 = 0$. The roots are -3 and -1, and the general solution is $y = Ae^{-3x} + Be^{-x}$.

Multiple Real Roots If $r_1 = r_2$, the solution of the differential equation is $y = e^{r_1x}(A + Bx)$.

Example $y'' + 4y + 4 = 0$. The characteristic equation is $m^2 + 4m + 4 = 0$ with roots -2 and -2. The solution is $y = e^{-2x}(A + Bx)$.

Complex Roots If the characteristic roots are $p \pm iq$, then the solution is $y = e^{px}(A \cos qx + B \sin qx)$.

Example The differential equation $My'' + Ay' + ky = 0$ represents the vibration of a linear system of mass M, spring constant k, and damping constant A. If $A < 2\sqrt{kM}$, the roots of the characteristic equation

$$Mm^2 + Am + k = 0 \text{ are complex } -\frac{A}{2M} \pm i\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}$$

and the solution is

$$y = e^{-(At/2M)}$$

$$\left\{c_1 \cos\left(\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}\right)t + ic_2 \sin\left(\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}\right)t\right\}$$

This solution is oscillatory, representing undercritical damping.

All these results generalize to homogeneous linear differential equations with constant coefficients of order higher than 2. These equations (especially of order 2) have been much used because of the ease of solution. Oscillations, electric circuits, diffusion processes, and heat-flow problems are a few examples for which such equations are useful.

Second-Order Equations: Dependent Variable Missing Such an equation is of the form

$$F\left(x, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0$$

It can be reduced to a first-order equation by substituting $p = dy/dx$ and $dp/dx = d^2y/dx^2$.

Second-Order Equations: Independent Variable Missing Such an equation is of the form

$$F\left(y, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0$$

Set
$$\frac{dy}{dx} = p, \quad \frac{d^2y}{dx^2} = p\frac{dp}{dy}$$

The result is a first-order equation in p,

$$F\left(y, p, p\frac{dp}{dy}\right) = 0$$

Example The capillary curve for one vertical plate is given by

$$\frac{d^2y}{dx^2} = \frac{4y}{c^2}\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}$$

Its solution by this technique is

$$x + \sqrt{c^2 - y^2} - \sqrt{c^2 - h_0^2} = \frac{c}{2}\left(\cosh^{-1}\frac{c}{y} - \cosh^{-1}\frac{c}{h_0}\right)$$

where c, h_0 are physical constants.

Example The equation governing chemical reaction in a porous catalyst in plane geometry of thickness L is

$$D\frac{d^2c}{dx^2} = k\,f(c), \quad \frac{dc}{dx}(0) = 0, \quad c(L) = c_0$$

where D is a diffusion coefficient, k is a reaction rate parameter, c is the concentration, $k\,f(c)$ is the rate of reaction, and c_0 is the concentration at the

boundary. Making the substitution $p = \frac{dc}{ds}$ gives (Finlayson, 1980, p. 92)

$$p\,\frac{dp}{dc} = \frac{k}{D} f(c)$$

Integrating gives
$$\frac{p^2}{2} = \frac{k}{D} \int_{c(0)}^{c} f(c)\,dc$$

If the reaction is very fast, $c(0) \approx 0$ and the average reaction rate is related to $p(L)$. This variable is given by

$$p(L) = \left[\frac{2k}{D} \int_0^{c0} f(c)\,dc\right]^{1/2}$$

Thus, the average reaction rate can be calculated without solving the complete problem.

Linear Nonhomogeneous Differential Equations

***Linear Differential Equations Right-Hand Member* f(x) ≠ 0** Again the specific remarks for $y'' + ay' + by = f(x)$ apply to differential equations of similar type but higher order. We shall discuss two general methods.

Method of Undetermined Coefficients Use of this method is limited to equations exhibiting both constant coefficients and particular forms of the function $f(x)$. In most cases $f(x)$ will be a sum or product of functions of the type constant, x^n (n a positive integer), e^{mx}, $\cos kx$, $\sin kx$. When this is the case, the solution of the equation is $y = H(x) + P(x)$, where $H(x)$ is a solution of the homogeneous equations found by the method of the preceding subsection and $P(x)$ is a particular integral found by using the following table subject to these conditions: (1) When $f(x)$ consists of the sum of several terms, the appropriate form of $P(x)$ is the sum of the particular integrals corresponding to these terms individually. (2) When a term in any of the trial integrals listed is already a part of the homogeneous solution, the indicated form of the particular integral is multiplied by x.

Form of Particular Integral

If $f(x)$ is	Then $P(x)$ is
a (constant)	A (constant)
ax^n	$A_n x^n + A_{n-1}x^{n-1} + \cdots A_1 x + A_0$
ae^{rx}	Be^{rx}
$c \cos kx$, $d \sin kx$	$A \cos kx + B \sin kx$
$gx^n e^{rx} \cos kx$, $hx^n e^{rx} \sin kx$	$(A_n x^n + \cdots + A_0)e^{rx} \cos kx + (B_n x^n + \cdots + B_0)e^{rx} \sin kx$

Since the form of the particular integral is known, the constants may be evaluated by substitution in the differential equation.

Example $y'' + 2y' + y = 3e^{2x} - \cos x + x^3$. The characteristic equation is $(m + 1)^2 = 0$ so that the homogeneous solution is $y = (c_1 + c_2 x)e^{-x}$. To find a particular solution we use the trial solution from the table, $y = a_1 e^{2x} + a_2 \cos x + a_3 \sin x + a_4 x^3 + a_5 x^2 + a_6 x + a_7$. Substituting this in the differential equation collecting and equating like terms, there results $a_1 = \frac{1}{3}$, $a_2 = 0$, $a_3 = -\frac{1}{2}$, $a_4 = 1$, $a_5 = -6$, $a_6 = 18$, and $a_7 = -24$. The solution is $y = (c_1 + c_2 x)e^{-x} + \frac{1}{3}e^{2x} - \frac{1}{2}\sin x + x^3 - 6x^2 + 18x - 24$.

Method of Variation of Parameters This method is applicable to any linear equation. The technique is developed for a second-order equation but immediately extends to higher order. Let the equation be $y'' + a(x)y' + b(x)y = R(x)$ and let the solution of the homogeneous equation, found by some method, be $y = c_1 f_1(x) + c_2 f_2(x)$. It is now assumed that a particular integral of the differential equation is of the form $P(x) = uf_1 + vf_2$ where u, v are functions of x to be determined by two equations. One equation results from the requirement that $uf_1 + vf_2$ satisfy the differential equation, and the other is a degree of freedom open to the analyst. The best choice proves to be

$$u'f_1 + v'f_2 = 0 \qquad \text{and} \qquad u'f_1' + v'f_2' = R(x)$$

Then
$$u' = \frac{du}{dx} = -\frac{f_2}{f_1 f_2' - f_2 f_1'} R(x)$$

$$v' = \frac{dv}{dx} = \frac{f_1}{f_1 f_2' - f_2 f_1'} R(x)$$

and since f_1, f_2, and R are known u, v may be found by direct integration.

Perturbation Methods If the ordinary differential equation has a parameter that is small and is not multiplying the highest derivative, perturbation methods can give solutions for small values of the parameter.

Example Consider the differential equation for reaction and diffusion in a catalyst; the reaction is second order: $c'' = ac^2$, $c'(0) = 0$, $c(1) = 1$. The solution is expanded in the following Taylor series in a.

$$c(x, a) = c_0(x) + ac_1(x) + a^2 c_2(x) + \cdots$$

The goal is to find equations governing the functions $\{c_i(x)\}$ and solve them. Substitution into the equations gives the following equations:

$$c_0''(x) + a\,c_1''(x) + a^2 c_2''(x) + \cdots = a[c_0(x) + ac_1(x) + a^2 c_2(x) + \cdots]^2$$

$$c_0'(0) + ac_1'(0) + a^2 c_2'(0) + \cdots = 0$$

$$c_0(1) + ac_1(1) + a^2 c_2(1) + \cdots = 1$$

Like terms in powers of a are collected to form the individual problems.

$$c_0'' = 0, \quad c_0'(0) = 0, \quad c_0(1) = 1$$

$$c_1'' = c_0^2, \quad c_1'(0) = 0, \quad c_1(1) = 0$$

$$c_2'' = 2c_0 c_1, \quad c_2'(0) = 0, \quad c_2(1) = 0$$

The solution proceeds in turn.

$$c_0(x) = 1, \quad c_1(x) = \frac{(x^2 - 1)}{2}, \quad c_2(x) = \frac{5 - 6x^2 + x^4}{12}$$

SPECIAL DIFFERENTIAL EQUATIONS [SEE ABRAMOWITZ AND STEGUN (1972)]

Euler's Equation The linear equation $x^n y^{(n)} + a_1 x^{n-1} y^{(n-1)} + \cdots + a_{n-1} xy' + a_n y = R(x)$ can be reduced to a linear equation with constant coefficients by the change of variable $x = e^t$. To solve the homogeneous equation substitute $y = x^r$ into it, cancel the powers of x, which are the same for all terms, and solve the resulting polynomial for r. In case of multiple or complex roots there results the form $y = x^r(\log x)^r$ and $y = x^\alpha[\cos(\beta \log x) + i \sin(\beta \log x)]$.

Bessel's Equation The linear equation $x^2(d^2y/dx^2) + (1 - 2\alpha)x(dy/dx) + [\beta^2\gamma^2 x^{2\gamma} + (\alpha^2 - p^2\gamma^2)]y = 0$ is the general Bessel equation. By series methods, not to be discussed here, this equation can be shown to have the solution

$$y = Ax^\alpha J_p(\beta x^\gamma) + Bx^\alpha J_{-p}(\beta x^\gamma) \qquad p \text{ not an integer or zero}$$

$$y = Ax^\alpha J_p(\beta x^\gamma) + Bx^\alpha Y_p(\beta x^\gamma) \qquad p \text{ an integer}$$

where
$$J_p(x) = \left(\frac{x}{2}\right)^p \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k!\,\Gamma(p + k + 1)}$$

$$J_{-p}(x) = \left(\frac{x}{2}\right)^{-p} \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k!\,\Gamma(k + 1 - p)} \qquad p \text{ not an integer}$$

$$\Gamma(n) = \int_0^\infty x^{n-1} e^{-x}\,dx \qquad n > 0$$

is the gamma function. For p an integer

$$J_p(x) = \left(\frac{x}{2}\right)^p \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k!\,(p + k)!}$$

(Bessel function of the first kind of order p)

$$Y_p(x) = \frac{[J_p(x)\cos(p\pi) - J_{-p}(x)]}{\sin(p\pi)}$$

(replace right-hand side by limiting value if p is an integer or zero).

The series converge for all x. Much of the importance of Bessel's equation and Bessel functions lies in the fact that the solutions of numerous linear differential equations can be expressed in terms of them.

Legendre's Equation The Legendre equation $(1 - x^2)y'' - 2xy' + n(n + 1)y = 0$, $n \geq 0$, has the solution P_n for n an integer.
The polynomials P_n are the so-called Legendre polynomials, $P_0(x) = 1$, $P_1(x) = x$, $P_2(x) = \frac{1}{2}(3x^2 - 1)$, $P_3(x) = \frac{1}{2}(5x^3 - 3x)$, ...

For n positive and not an integer, see Abramowitz and Stegun (1972).

Laguerre's Equation The Laguerre equation $x(d^2y/dx^2) + (c - x)(dy/dx) - ay = 0$ is satisfied by the confluent hypergeometric function. See Abramowitz and Stegun (1972) and Kreszig (1999).

Hermite's Equation The Hermite equation $y'' - 2xy' + 2ny = 0$ is satisfied by the Hermite polynomial of degree n, $y = AH_n(x)$ if n is a positive integer or zero. $H_0(x) = 1$, $H_1(x) = 2x$, $H_2(x) = 4x^2 - 2$, $H_3(x) = 8x^3 - 12x$, $H_4(x) = 16x^4 - 48x^2 + 12$, $H_{r+1}(x) = 2xH_r(x) - 2rH_{r-1}(x)$.

Chebyshev's Equation The equation $(1 - x^2)y'' - xy' + n^2y = 0$ for n a positive integer or zero is satisfied by the nth Chebyshev polynomial $y = AT_n(x)$. $T_0(x) = 1$, $T_1(x) = x$, $T_2(x) = 2x^2 - 1$, $T_3(x) = 4x^3 - 3x$, $T_4(x) = 8x^4 - 8x^2 + 1$; $T_{r+1}(x) = 2xT_r(x) - T_{r-1}(x)$.

PARTIAL DIFFERENTIAL EQUATIONS

The analysis of situations involving two or more independent variables frequently results in a partial differential equation.

Example The equation $\partial T/\partial t = K(\partial^2 T/\partial x^2)$ represents the unsteady one-dimensional conduction of heat.

Example The equation for the unsteady transverse motion of a uniform beam clamped at the ends is

$$\frac{\partial^4 y}{\partial x^4} + \frac{\rho}{EI}\frac{\partial^2 y}{\partial t^2} = 0$$

Example The expansion of a gas behind a piston is characterized by the simultaneous equations

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} + \frac{c^2}{\rho}\frac{\partial \rho}{\partial x} = 0 \quad \text{and} \quad \frac{\partial \rho}{\partial t} + u\frac{\partial \rho}{\partial x} + \rho\frac{\partial u}{\partial x} = 0$$

The partial differential equation $\partial^2 f/\partial x\, \partial y = 0$ can be solved by two integrations yielding the solution $f = g(x) + h(y)$, where $g(x)$ and $h(y)$ are arbitrary differentiable functions. This result is an example of the fact that the general solution of partial differential equations involves arbitrary functions in contrast to the solution of ordinary differential equations, which involve only arbitrary constants. A number of methods are available for finding the general solution of a partial differential equation. In most applications of partial differential equations the general solution is of limited use. In such applications the solution of a partial differential equation must satisfy both the equation and certain auxiliary conditions called **initial** and/or **boundary** conditions, which are dictated by the problem. Examples of these include those in which the wall temperature is a fixed constant $T(x_0) = T_0$, there is no diffusion across a nonpermeable wall, and the like. In ordinary differential equations these auxiliary conditions allow definite numbers to be assigned to the constants of integration.

Partial Differential Equations of Second and Higher Order Many of the applications to scientific problems fall naturally into partial differential equations of second order, although there are important exceptions in elasticity, vibration theory, and elsewhere.

A second-order differential equation can be written as

$$a\frac{\partial^2 u}{\partial x^2} + b\frac{\partial^2 u}{\partial x \partial y} + c\frac{\partial^2 u}{\partial y^2} = f$$

where a, b, c, and f depend upon $x, y, u, \partial u/\partial x$, and $\partial u/\partial y$. This equation is hyperbolic, parabolic, or elliptic, depending on whether the discriminant $b^2 - 4ac$ is >0, $=0$, or <0, respectively. Since a, b, c, and f depend on the solution, the type of equation can be different at different x and y locations. If the equation is hyperbolic, discontinuities can be propagated. See Courant and Hilbert (1953, 1962) and LeVeque, R. J., *Numerical Methods for Conservation Laws,* Birkhäuser, Basel (1992).

Phenomena of **propagation** such as vibrations are characterized by equations of "hyperbolic" type which are essentially different in their properties from other classes such as those which describe equilibrium (elliptic) or unsteady diffusion and heat transfer (parabolic). Prototypes are as follows:

Elliptic Laplace's equation $\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2 = 0$ and Poisson's equation $\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2 = g(x, y)$ do not contain the variable time explicitly and consequently represent equilibrium configurations. Laplace's equation is satisfied by static electric or magnetic potential at points free from electric charges or magnetic poles. Other important functions satisfying Laplace's equation are the velocity potential of the irrotational motion of an incompressible fluid, used in hydrodynamics; the steady temperature at points in a homogeneous solid, and the steady state of diffusion through a homogeneous body.

Parabolic The heat equation $\partial T/\partial t = \partial^2 T/\partial x^2 + \partial^2 T/\partial y^2$ represents nonequilibrium or unsteady states of heat conduction and diffusion.

Hyperbolic The wave equation $\partial^2 u/\partial t^2 = c^2(\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2)$ represents wave propagation of many varied types.

Quasilinear first-order differential equations are like

$$a\frac{\partial u}{\partial x} + b\frac{\partial u}{\partial y} = f$$

where a, b, and f depend on x, y, and u, with $a^2 + b^2 \neq 0$. This equation can be solved using the method of characteristics, which writes the solution in terms of a parameter s, which defines a path for the characteristic.

$$\frac{dx}{ds} = a, \quad \frac{dy}{ds} = b, \quad \frac{du}{ds} = f$$

These equations are integrated from some initial conditions. For a specified value of s, the value of x and y shows the location where the solution is u. The equation is semilinear if a and b depend just on x and y (and not u), and the equation is linear if a, b, and f all depend on x and y, but not u. Such equations give rise to shock propagation, and conditions have been derived to deduce the presence of shocks. Courant and Hilbert (1953, 1962); Rhee, H. K., R. Aris, and N. R. Amundson, *First-Order Partial Differential Equations,* vol. I, *Theory and Applications of Single Equations,* Prentice-Hall, Englewood Cliffs, N.J. (1986); and LeVeque (1992), ibid.

An example of a linear hyperbolic equation is the advection equation for flow of contaminants when the x and y velocity components are u and v, respectively.

$$\frac{\partial c}{\partial t} + u\frac{\partial c}{\partial x} + v\frac{\partial c}{\partial y} = 0$$

The equations for flow and adsorption in a packed bed or chromatography column give a quasilinear equation.

$$\phi\frac{\partial c}{\partial t} + \phi\, u\frac{\partial c}{\partial x} + (1 - \phi)\frac{df}{dc}\frac{\partial c}{\partial t} = 0$$

Here $n = f(c)$ is the relation between concentration on the adsorbent and fluid concentration.

The solution of problems involving partial differential equations often revolves about an attempt to reduce the partial differential equation to one or more ordinary differential equations. The solutions of the ordinary differential equations are then combined (if possible) so that the boundary conditions as well as the original partial differential equation are simultaneously satisfied. Three of these techniques are illustrated.

Similarity Variables The physical meaning of the term "similarity" relates to internal similitude, or self-similitude. Thus, similar solutions in boundary-layer flow over a horizontal flat plate are those for which the horizontal component of velocity u has the property that two velocity profiles located at different coordinates x differ only by a scale factor. The mathematical interpretation of the term similarity is a transformation of variables carried out so that a reduction in the number of independent variables is achieved. There are essentially two methods for finding similarity variables, "separation of variables" (not the classical concept) and the use of "continuous transformation groups." The basic theory is available in Ames (1965).

Example The equation $\partial\theta/\partial x = (A/y)(\partial^2\theta/\partial y^2)$ with the boundary conditions $\theta = 0$ at $x = 0$, $y > 0$; $\theta = 0$ at $y = \infty$, $x > 0$; $\theta = 1$ at $y = 0$, $x > 0$ represents the nondimensional temperature θ of a fluid moving past an infinitely wide flat plate immersed in the fluid. Turbulent transfer is neglected, as is molecular transport except in the y direction. It is now assumed that the equation and the boundary conditions can be satisfied by a solution of the form $\theta = f(y/x^n) = f(u)$, where $\theta = 0$ at $u = \infty$ and $\theta = 1$ at $u = 0$. The purpose here is to replace the independent variables x and y by the single variable u when it is hoped that a value of n exists which will allow x and y to be completely eliminated in the equation. In this case since $u = y/x^n$, there results after some calculation $\partial\theta/\partial x = -(nu/x)(d\theta/du)$, $\partial^2\theta/\partial y^2 = (1/x^{2n})(d^2\theta/du^2)$, and when these are substituted in the equation, $-(1/x)nu(d\theta/du) = (1/x^{3n})(A/u)(d^2\theta/du^2)$. For this to be a function of u only, choose $n = \frac{1}{3}$. There results $(d^2\theta/du^2) + (u^2/3A)(d\theta/du) = 0$. Two integrations and use of the boundary conditions for this ordinary differential equation give the solution

$$\theta = \int_u^\infty \exp(-u^3/9A)\,du \Big/ \int_0^\infty \exp(-u^3/9A)\,du$$

Group Method The type of transformation can be deduced using group theory. For a complete exposition, see Ames (1965) and Hill, J. M., *Differential Equations and Group Methods for Scientists and Engineers*, CRC Press, New York (1992); a shortened version is in Finlayson (1980, 2003). Basically, a similarity transformation should be considered when one of the independent variables has no physical scale (perhaps it goes to infinity). The boundary conditions must also simplify (and combine) since each transformation leads to a differential equation with one fewer independent variable.

Example A similarity variable is found for the problem

$$\frac{\partial c}{\partial t} = \frac{\partial}{\partial x}\left(\frac{D(c)}{D}\frac{\partial c}{\partial x}\right), \quad c(0,t) = 1, \quad c(\infty,t) = 0, \quad c(x,0) = 0$$

Note that the length dimension goes to infinity, so that there is no length scale in the problem statement; this is a clue to try a similarity transformation. The transformation examined here is

$$\bar{t} = a^\alpha t, \quad \bar{x} = a^\beta x, \quad \bar{c} = a^\gamma c$$

With this substitution, the equation becomes

$$a^{\alpha-\gamma}\frac{\partial \bar{c}}{\partial \bar{t}} = a^{2\beta-\gamma}\frac{\partial}{\partial \bar{x}}\left[D(a^{-\gamma}\bar{c})\frac{\partial \bar{c}}{\partial \bar{x}}\right]$$

Group theory says a system is conformally invariant if it has the same form in the new variables; here, that is

$$\gamma = 0, \quad \alpha - \gamma = 2\beta - \gamma, \quad \text{or } \alpha = 2\beta$$

The invariants are

$$\eta = \frac{x}{t^\delta}, \quad \delta = \frac{\beta}{\alpha}$$

and the solution is

$$c(x,t) = f(\eta)t^{\gamma/\alpha}$$

We can take $\gamma = 0$ and $\delta = \beta/\alpha = \frac{1}{2}$. Note that the boundary conditions combine because the point $x = \infty$ and $t = 0$ give the same value of η and the conditions on c at $x = \infty$ and $t = 0$ are the same. We thus make the transformation

$$\eta = \frac{x}{\sqrt{4D_0 t}}, \quad c(x,t) = f(\eta)$$

The use of the 4 and D_0 makes the analysis below simpler. The result is

$$\frac{d}{d\eta}\left[\frac{D(c)}{D_0}\frac{df}{d\eta}\right] + 2\eta\frac{df}{d\eta} = 0, \quad f(0) = 1, \quad f(\infty) = 0$$

Thus, we solve a two-point boundary value problem instead of a partial differential equation. When the diffusivity is constant, the solution is the error function, a tabulated function.

$$c(x,t) = 1 - \text{erf}\,\eta = \text{erfc}\,\eta$$

$$\text{erf}\,\eta = \int_0^\eta e^{-\xi^2}\,d\xi \Big/ \int_0^\infty e^{-\xi^2}\,d\xi$$

Separation of Variables This is a powerful, well-utilized method which is applicable in certain circumstances. It consists of assuming that the solution for a partial differential equation has the form $U = f(x)g(y)$. If it is then possible to obtain an ordinary differential equation on one side of the equation depending only on x and on the other side only on y, the partial differential equation is said to be separable in the variables x, y. If this is the case, one side of the equation is a function of x alone and the other of y alone. The two can be equal only if each is a constant, say λ. Thus the problem has again been reduced to the solution of ordinary differential equations.

Example Laplace's equation $\partial^2V/\partial x^2 + \partial^2V/\partial y^2 = 0$ plus the boundary conditions $V(0, y) = 0$, $V(l, y) = 0$, $V(x, \infty) = 0$, $V(x, 0) = f(x)$ represents the steady-state potential in a thin plate (in z direction) of infinite extent in the y direction and of width l in the x direction. A potential $f(x)$ is impressed (at $y = 0$) from $x = 0$ to $x = 1$, and the sides are grounded. To obtain a solution of this boundary-value problem assume $V(x, y) = f(x)g(y)$. Substitution in the differential equation yields $f''(x)g(y) + f(x)g''(y) = 0$, or $g''(y)/g(y) = -f''(x)/f(x) = \lambda^2$ (say). This system becomes $g''(y) - \lambda^2 g(y) = 0$ and $f''(x) + \lambda^2 f(x) = 0$. The solutions of these ordinary differential equations are respectively $g(y) = Ae^{\lambda y} + Be^{-\lambda y}$, $f(x) = C \sin \lambda x + D \cos \lambda x$. Then $f(x)g(y) = (Ae^{\lambda y} + Be^{-\lambda y})(C \sin \lambda x + D \cos \lambda x)$. Now $V(0, y) = 0$ so that $f(0)g(y) = (Ae^{\lambda y} + Be^{-\lambda y})D \equiv 0$ for all y. Hence $D = 0$. The solution then has the form $\sin \lambda x\,(Ae^{\lambda y} + Be^{-\lambda y})$ where the multiplicative constant C has been eliminated. Since $V(l, y) = 0$, $\sin \lambda l(Ae^{\lambda y} + Be^{-\lambda y}) \equiv 0$. Clearly the bracketed function of y is not zero, for the solution would then be the identically zero solution. Hence $\sin \lambda l = 0$ or $\lambda_n = n\pi/l$, $n = 1, 2, \ldots$ where $\lambda_n = n$th eigenvalue.

The solution now has the form $\sin(n\pi x/l)(Ae^{n\pi y/l} + Be^{-n\pi y/l})$. Since $V(x, \infty) = 0$, A must be taken to be zero because e^y becomes arbitrarily large as $y \to \infty$. The solution then reads $B_n \sin(n\pi x/l)e^{-n\pi y/l}$, where B_n is the multiplicative constant. The differential equation is linear and homogeneous so that $\sum_{n=1}^\infty B_n e^{-n\pi y/l} \sin(n\pi x/l)$ is also a solution. Satisfaction of the last boundary condition is ensured by taking

$$B_n = \frac{2}{l}\int_0^l f(x)\sin(n\pi x/l)\,dx = \text{Fourier sine coefficients of } f(x)$$

Further, convergence and differentiability of this series are established quite easily. Thus the solution is

$$V(x, y) = \sum_{n=1}^\infty B_n e^{-n\pi y/l}\sin\frac{n\pi x}{l}$$

Example The diffusion problem in a slab of thickness L

$$\frac{\partial c}{\partial t} = D\frac{\partial^2 c}{\partial x^2}, \quad c(0,t) = 1, \quad c(L,t) = 0, \quad c(x,0) = 0$$

can be solved by separation of variables. First transform the problem so that the boundary conditions are homogeneous (having zeros on the right-hand side). Let

$$c(x,t) = 1 - \frac{x}{L} + u(x,t)$$

Then $u(x, t)$ satisfies

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2}, \quad u(x,0) = \frac{x}{L} - 1, \quad u(0,t) = 0, \quad u(L,t) = 0$$

Assume a solution of the form $u(x, t) = X(x)\,T(t)$, which gives

$$\frac{1}{DT}\frac{dT}{dt} = \frac{1}{X}\frac{d^2X}{dx^2}$$

Since both sides are constant, this gives the following ordinary differential equations to solve.

$$\frac{1}{DT}\frac{dT}{dt} = -\lambda, \quad \frac{1}{X}\frac{d^2X}{dx^2} = -\lambda$$

The solution of these is

$$T = A\,e^{-\lambda Dt}, \quad X = B\cos\sqrt{\lambda}\,x + E\sin\sqrt{\lambda}\,x$$

The combined solution for $u(x,t)$ is

$$u = A\,(B\cos\sqrt{\lambda}\,x + E\sin\sqrt{\lambda}\,x)\,e^{-\lambda Dt}$$

Apply the boundary condition that $u(0,t) = 0$ to give $B = 0$. Then the solution is

$$u = A\,(\sin\sqrt{\lambda}\,x)e^{-\lambda Dt}$$

where the multiplicative constant E has been eliminated. Apply the boundary condition at $x = L$.

$$0 = A\,(\sin\sqrt{\lambda}\,L)e^{-\lambda Dt}$$

This can be satisfied by choosing $A = 0$, which gives no solution. However, it can also be satisfied by choosing λ such that

$$\sin\sqrt{\lambda}\,L = 0, \quad \sqrt{\lambda}\,L = n\,\pi$$

Thus

$$\lambda = \frac{n^2\pi^2}{L^2}$$

The combined solution can now be written as

$$u = A\left(\frac{\sin n\pi x}{L}\right)e^{-n^2\pi^2 Dt/L^2}$$

Since the initial condition must be satisfied, we use an infinite series of these functions.

$$u = \sum_{n=1}^{\infty} A_n\left(\frac{\sin n\pi x}{L}\right)e^{-n^2\pi^2 Dt/L^2}$$

At $t = 0$, we satisfy the initial condition.

$$\frac{x}{L} - 1 = \sum_{n=1}^{\infty} A_n\left(\frac{\sin n\pi x}{L}\right)$$

This is done by multiplying the equation by

$$\frac{\sin m\pi x}{L}$$

and integrating over x: $0 \to L$. (This is the same as minimizing the mean-square error of the initial condition.) This gives

$$\frac{A_m L}{2} = \int_0^L \left(\frac{x}{L} - 1\right)\sin\frac{m\pi x}{L}\,dx$$

which completes the solution.

Integral-Transform Method A number of integral transforms are used in the solution of differential equations. Only one, the Laplace transform, will be discussed here [for others, see "Integral Transforms (Operational Methods)"]. The one-sided Laplace transform indicated by $L[f(t)]$ is defined by the equation $L[f(t)] = \int_0^\infty f(t)e^{-st}\,dt$. It has numerous important properties. The ones of interest here are $L[f'(t)] = sL[f(t)] - f(0)$; $L[f''(t)] = s^2L[f(t)] - sf(0) - f'(0)$; $L[f^{(n)}(t)] = s^nL[f(t)] - s^{n-1}f(0) - s^{n-2}f'(0) - \cdots - f^{(n-1)}(0)$ for ordinary derivatives. For partial derivatives an indication of which variable is being transformed avoids confusion. Thus, if

$$y = y(x, t), \quad L_t\left[\frac{\partial y}{\partial t}\right] = sL[y(x, t)] - y(x, 0)$$

whereas

$$L_t\left[\frac{\partial y}{\partial x}\right] = \frac{dL_t[y(x, t)]}{dx}$$

since $L[y(x, t)]$ is "really" only a function of x. Otherwise the results are similar. These facts coupled with the linearity of the transform, i.e., $L[af(t) + bg(t)] = aL[f(t)] + bL[g(t)]$, make it a useful device in solving some linear differential equations. Its use reduces the solution of ordinary differential equations to the solution of algebraic equations for $L[y]$. The inverse transform must be obtained either from tables or by use of complex inversion methods.

Example The equation $\partial c/\partial t = D(\partial^2 c/\partial x^2)$ represents the diffusion in a semi-infinite medium, $x \ge 0$. Under the boundary conditions $c(0, t) = c_0$, $c(x, 0) = 0$ find a solution of the diffusion equation. By taking the Laplace transform of both sides with respect to t,

$$\int_0^\infty e^{-st}\frac{\partial^2 c}{\partial x^2}\,dt = \frac{1}{D}\int_0^\infty e^{-st}\frac{\partial c}{\partial t}\,dt$$

or

$$\frac{d^2F}{dx^2} = (1/D)sF - c(x, 0) = \frac{sF}{D}$$

where $F(x, s) = L_t[c(x, t)]$. Hence

$$\frac{d^2F}{dx^2} - \left(\frac{s}{D}\right)F = 0$$

The other boundary condition transforms into $F(0, s) = c_0/s$. Finally the solution of the ordinary differential equation for F subject to $F(0, s) = c_0/s$ and F remains finite as $x \to \infty$ is $F(x, s) = (c_0/s)e^{-\sqrt{s/D}x}$. Reference to a table shows that the function having this as its Laplace transform is

$$c(x, t) = c_0\left[1 - \frac{2}{\sqrt{\pi}}\int_0^{x/2\sqrt{Dt}} e^{-u^2}\,du\right] = C_0 \operatorname{erfc}\left(\frac{x}{\sqrt{4Dt}}\right)$$

Matched-Asymptotic Expansions Sometimes the coefficient in front of the highest derivative is a small number. Special perturbation techniques can then be used, provided the proper scaling laws are found. See Kevorkian, J., and J. D. Cole, *Perturbation Methods in Applied Mathematics*, Springer-Verlag, New York (1981); and Lagerstrom, P. A., *Matched Asymptotic Expansions: Ideas and Techniques*, Springer-Verlag, New York (1988).

DIFFERENCE EQUATIONS

References: Elaydi, Saber, and S. N. Elaydi, *An Introduction to Difference Equations*, Springer-Verlag, New York (1999); Fulford, G., P. Forrester, and A. Jones, *Modelling with Differential and Difference Equations*, Cambridge University Press, New York (1997); Goldberg, S., *Introduction to Difference Equations*, Dover (1986); Kelley, W. G., and A. C. Peterson, *Difference Equations : An Introduction with Applications*, 2d ed., Harcourt/Academic Press, San Diego (2001).

Certain situations are such that the independent variable does not vary continuously but has meaning only for discrete values. Typical illustrations occur in the stagewise processes found in chemical engineering such as distillation, staged extraction systems, and absorption columns. In each of these the operation is characterized by a finite between-stage change of the dependent variable in which the independent variable is the integral number of the stage. The importance of difference equations is twofold: (1) to analyze problems of the type described and (2) to obtain approximate solutions of problems which lead, in their formulation, to differential equations. In this subsection only problems of analysis are considered; the application to approximate solutions is considered under "Numerical Analysis and Approximate Methods."

ELEMENTS OF THE CALCULUS OF FINITE DIFFERENCES

Let $y = f(x)$ be defined for discrete equidistant values of x, which will be denoted by x_n. The corresponding value of y will be written $y_n = f(x_n)$. The first forward difference of $f(x)$ denoted by $\Delta f(x) = f(x + h) - f(x)$ where $h = x_n - x_{n-1}$ = interval length.

Example Let $f(x) = x^2$. Then $\Delta f(x) = (x + h)^2 - x^2 = 2hx + h^2$.

The second forward difference is obtained by taking the difference of the first; thus $\Delta\Delta f(x) = \Delta^2 f(x) = \Delta f(x + h) - \Delta f(x) = f(x + 2h) - 2f(x + h) + f(x)$.

Example $f(x) = x^2$, $\Delta^2 f(x) = \Delta[\Delta f(x)] = \Delta 2hx + \Delta h^2 = 2h(x + h) - 2hx + h^2 - h^2 = 2h^2$.

Similarly the nth forward difference is defined by the relation $\Delta^n f(x) = \Delta[\Delta^{n-1}f(x)]$. Other difference relations are also quite useful. Some of these are $\nabla f(x) = f(x) - f(x - h)$, which is called the backward difference, and $\delta f(x) = f[x + (h/2)] - f[x - (h/2)]$, called the central difference. Some properties of the operator Δ are quite important. If C is any constant, $\Delta C = 0$; if $f(x)$ is any function of period h, $\Delta f(x) = 0$ (in fact, periodic functions of period h play the same role here as constants do in the differential calculus); $\Delta[f(x) + g(x)] = \Delta f(x) + \Delta g(x)$; $\Delta^m[\Delta^n f(x)] = \Delta^{m+n} f(x)$; $\Delta[f(x)g(x)] = f(x)\,\Delta g(x) + g(x + h)\,\Delta f(x)$

$$\Delta\left[\frac{f(x)}{g(x)}\right] = \frac{g(x)\,\Delta f(x) - f(x)\,\Delta g(x)}{g(x)g(x + h)}$$

Example $\Delta(x \sin x) = x\Delta \sin x + \sin(x + h)\,\Delta x = 2x \sin(h/2)\cos[x + (h/2)] + h \sin(x + h)$.

DIFFERENCE EQUATIONS

A difference equation is a relation between the differences and the independent variable, $\phi(\Delta^n y, \Delta^{n-1}y, \ldots, \Delta y, y, x) = 0$, where ϕ is some

given function. The general case in which the interval between the successive points is any real number h, instead of 1, can be reduced to that with interval size 1 by the substitution $x = hx'$. Hence all further difference-equation work will assume the interval size between successive points is 1.

Example $f(x + 1) - (\alpha + 1)f(x) + \alpha f(x - 1) = 0$. Common notation usually is $y_x = f(x)$. This equation is then written $y_{x+1} - (\alpha + 1)y_x + \alpha y_{x-1} = 0$.

Example $y_{x+2} + 2y_x y_{x+1} + y_x = x^2$.

Example $y_{x+1} - y_x = 2^x$.

The order of the difference equation is the difference between the largest and smallest arguments when written in the form of the second example. The first and second examples are both of order 2, while the third example is of order 1. A linear difference equation involves no products or other nonlinear functions of the dependent variable and its differences. The first and third examples are linear, while the second example is nonlinear.

A solution of a difference equation is a relation between the variables which satisfies the equation. If the difference equation is of order n, the general solution involves n arbitrary constants. The techniques for solving difference equations resemble techniques used for differential equations.

Equation $\Delta^n y = a$ The solution of $\Delta^n y = a$, where a is a constant, is a polynomial of degree n plus an arbitrary periodic function of period 1. That is, $y = (ax^n/n!) + c_1x^{n-1} + c_2x^{n-2} + \cdots + c_n + f(x)$, where $f(x + 1) = f(x)$.

Example $\Delta^3 y = 6$. The solution is $y = x^3 + c_1x^2 + c_2x + c_3 + f(x)$; c_1, c_2, c_3 are arbitrary constants, and $f(x)$ is an arbitrary periodic function of period 1.

Equation $y_{x+1} - y_x = \phi(x)$ This equation states that the first difference of the unknown function is equal to the given function $\phi(x)$. The solution by analogy with solving the differential equation $dy/dx = \phi(x)$ by integration is obtained by "finite integration" or summation. When there are only a finite number of data points, this is easily accomplished by writing $y_x = y_0 + \sum_{t=1}^{x} \phi(t - 1)$, where the data points are numbered from 1 to x. This is the only situation considered here.

Examples If $\phi(x) = 1$, $y_x = x$. If $\phi(x) = x$, $y_x = [x(x - 1)]/2$. If $\phi(x) = a^x$, $a \neq 0$, $y_x = a^x/(a - 1)$. In all cases $y_0 = 0$.

Other examples may be evaluated by using summation, that is, $y_2 = y_1 + \phi(1)$, $y_3 = y_2 + \phi(2) = y_1 + \phi(1) + \phi(2)$, $y_4 = y_3 + \phi(3) = y_1 + \phi(1) + \phi(2) + \phi(3), \ldots, y_x = y_1 + \sum_{t=1}^{x-1} \phi(t)$.

Example $y_{x+1} - ry_x = 1$, r constant, $x > 0$ and $y_0 = 1$. $y_1 = 1 + r$, $y_2 = 1 + r + r^2, \ldots, y_x = 1 + r + \cdots + r^x = (1 - r^{x+1})/(1 - r)$ for $r \neq 1$ and $y_x = 1 + x$ for $r = 1$.

Linear Difference Equations The linear difference equation of order n has the form $P_ny_{x+n} + P_{n-1}y_{x+n-1} + \cdots + P_1y_{x+1} + P_0y_x = Q(x)$ with $P_n \neq 0$ and $P_0 \neq 0$ and P_j; $j = 0, \ldots, n$ are functions of x.

Constant Coefficient and Q(x) = 0 (Homogeneous) The solution is obtained by trying a solution of the form $y_x = c\beta^x$. When this trial solution is substituted in the difference equation, a polynomial of degree n results for β. If the solutions of this polynomial are denoted by $\beta_1, \beta_2, \ldots, \beta_n$ then the following cases result: (1) if all the β_j's are real and unequal, the solution is $y_x = \sum_{j=1}^{n} c_j\beta_j^x$, where the $c_1, \ldots, c_n$ are arbitrary constants; (2) if the roots are real and repeated, say, β_j has multiplicity m, then the partial solution corresponding to β_j is $\beta_j^x(c_1 + c_2x + \cdots + c_mx^{m-1})$; (3) if the roots are complex conjugates, say, $a + ib = pe^{i\theta}$ and $a - ib = pe^{-i\theta}$, the partial solution corresponding to this pair is $p^x(c_1 \cos \theta x + ic_2 \sin \theta x)$; and (4) if the roots are multiple complex conjugates, say, $a + ib = pe^{i\theta}$ and $a - ib = pe^{-i\theta}$ are m-fold, then the partial solution corresponding to these is $p^x[(c_1 + c_2x + \cdots + c_mx^{m-1}) \cos \theta x + i(d_1 + d_2x + \cdots + d_mx^{m-1}) \sin \theta x]$.

Example The equation $y_{x+1} - (\alpha + 1)y_x + \alpha y_{x-1} = 0$, $y_0 = c_0$ and $y_{m+1} = x_{m+1}/k$ represents the steady-state composition of transferable material in the raffinate stream of a staged countercurrent liquid-liquid extraction system. Clearly y is a function of the stage number x. α is a combination of system constants. By using the trial solution $y_x = c\beta^x$, there results $\beta^2 - (\alpha + 1)\beta + \alpha = 0$, so that $\beta_1 = 1$, $\beta_2 = \alpha$. The general solution is $y_x = c_1 + c_2\alpha^x$. By using the side conditions, $c_1 = c_0 - c_2$, $c_2 = (y_{m+1} - c_0)/(\alpha^{m+1} - 1)$. The desired solution is $(y_x - c_0)/(y_{m+1} - c_0) = (\alpha^x - 1)/(\alpha^{m+1} - 1)$.

Example $y_{x+3} - 3y_{x+2} + 4y_x = 0$. By setting $y_x = c\beta^x$, there results $\beta^3 - 3\beta^2 + 4 = 0$ or $\beta_1 = -1$, $\beta_2 = 2$, $\beta_3 = 2$. The general solution is $y_x = c_1(-1)^x + 2^x(c_2 + c_3x)$.

Example $y_{x+1} - 2y_x + 2y_{x-1} = 0$. $\beta_1 = 1 + i$, $\beta_2 = 1 - i$. $p = \sqrt{1 + 1} = \sqrt{2}$, $\theta = \pi/4$. The solution is $y_x = 2^{x/2}[c_1 \cos (x\pi/4) + ic_2 \sin (x\pi/4)]$.

Constant Coefficients and Q(x) ≠ 0 (Nonhomogeneous) In this case the general solution is found by first obtaining the homogeneous solution, say, y_x^H and adding to it any particular solution with $Q(x) \neq 0$, say, y_x^P. There are several means of obtaining the particular solution.

Method of Undetermined Coefficients If $Q(x)$ is a product or linear combination of products of the functions e^{bx}, a^x, x^p (p a positive integer or zero) $\cos cx$ and $\sin cx$, this method may be used. The "families" $[a^x]$, $[e^{bx}]$, $[\sin cx, \cos cx]$ and $[x^p, x^{p-1}, \ldots, x, 1]$ are defined for each of the above functions in the following way: The family of a term f_x is the set of all functions of which f_x and all operations of the form a^{x+y}, $\cos c(x + y)$, $\sin c(x + y)$, $(x + y)^p$ on f_x and their linear combinations result in. The technique involves the following steps: (1) Solve the homogeneous system. (2) Construct the family of each term. (3) If the family has no representative in the homogeneous solution, assume y_x^P is a linear combination of the families of each term and determine the constants so that the equation is satisfied. (4) If a family has a representative in the homogeneous solution, multiply each member of the family by the smallest integral power of x for which all such representatives are removed and revert to step 3.

Example $y_{x+1} - 3y_x + 2y_{x-1} = 1 + a^x$. $a \neq 0$. The homogeneous solution is $y_x^H = c_1 + c_22^x$. The family of 1 is 1 and of a^x is a^x. However, 1 is a solution of the homogeneous system. Therefore, try $y_x^P = Ax + Ba^x$. Substituting in the equation there results

$$y_x = c_1 + c_22^x - x + \frac{a}{(a-1)(a-2)}a^x, \quad a \neq 1, a \neq 2$$

If $a = 1$, $y_x = c_1 + c_22^x - 2x$. If $a = 2$, $y_x = c_1 + c_22^x - x + x2^x$.

Example The family of x^23^x is $[x^23^x, x3^x, 3^x]$.

Method of Variation of Parameters This technique is applicable to general linear difference equations. It is illustrated for the second-order system $y_{x+2} + Ay_{x+1} + By_x = \phi(x)$. Assume that the homogeneous solution has been found by some technique and write $y_x^H = c_1u_x + c_2v_x$. Assume that a particular solution $y_x^P = D_xu_x + E_xv_x$. E_x and D_x can be found by solving the equations:

$$E_{x+1} - E_x = \frac{u_{x+1}\phi(x)}{u_{x+1}v_{x+2} - u_{x+2}v_{x+1}}$$

$$D_{x+1} - D_x = \frac{v_{x+1}\phi(x)}{v_{x+1}u_{x+2} - v_{x+2}u_{x+1}}$$

by summation. The general solution is then $y_x = y_x^P + y_x^H$.

Variable Coefficients The method of variation of parameters applies equally well to the linear difference equation with variable coefficients. Techniques are therefore needed to solve the homogeneous system with variable coefficients.

Equation $y_{x+1} - a_xy_x = 0$ By assuming that this equation is valid for $x \geq 0$ and $y_0 = c$, the solution is $y_x = c \prod_{n=1}^{x} a_{n-1}$.

Example $y_{x+1} + \dfrac{x+2}{x+1} y_x = 0$. The solution is

$$y_x = c\prod_{n=1}^{x}\left(-\frac{n+1}{n}\right) = c(-1)^x \, \frac{2}{1}\cdot\frac{3}{2}\cdots\frac{x+1}{x} = (-1)^x c(x+1)$$

Example $y_{x+1} - xy_x = 0$. The solution is $y_x = c(x - 1)!$

Reduction of Order If one homogeneous solution, say, u_x, can be found by inspection or otherwise, an equation of lower order can be obtained by the substitution $v_x = y_x/u_x$. The resultant equation must be satisfied by v_x = constant or $\Delta v_x = 0$. Thus the equation will be of reduced order if the new variable $U_x = \Delta(y_x/u_x)$ is introduced.

Example $(x+2)y_{x+2} - (x+3)y_{x+1} + y_x = 0$. By observation $u_x = 1$ is a solution. Set $U_x = \Delta y_x = y_{x+1} - y_x$. There results $(x+2)U_{x+1} - U_x = 0$, which is of degree one lower than the original equation. The complete solution for y_x is finally

$$y_x = c_0 \sum_{n=0}^{x} \frac{1}{n!} + c_1$$

Factorization If the difference equation can be factored, then the general solution can be obtained by solving two or more successive equations of lower order. Consider $y_{x+2} + A_x y_{x+1} + B_x y_x = \phi(x)$. If there exists a_x, b_x such that $a_x + b_x = -A_x$ and $a_x b_x = B_x$, then the difference equation may be written $y_{x+2} - (a_x + b_x)\, y_{x+1} + a_x b_x y_x = \phi(x)$. First solve $U_{x+1} - b_x U_x = \phi(x)$ and then $y_{x+1} - a_x y_x = U_x$.

Example $y_{x+2} - (2x+1)y_{x+1} + (x^2+x)y_x = 0$. Set $a_x = x$, $b_x = x+1$. Solve $u_{x+1} - (x+1)u_x = 0$ and then $y_{x+1} - xy_x = u_x$.

Substitution If it is possible to rearrange a difference equation so that it takes the form $af_{x+2}y_{x+2} + bf_{x+1}y_{x+1} + cf_x y_x = \phi(x)$ with a, b, c constants, then the substitution $u_x = f_x y_x$ reduces the equation to one with constant coefficients.

Example $(x+2)^2 y_{x+2} - 3(x+1)^2 y_{x+1} + 2x^2 y_x = 0$. Set $u_x = x^2 y_x$. The equation becomes $u_{x+2} - 3u_{x+1} + 2u_x = 0$, which is linear and easily solved by previous methods.

The substitution $u_x = y_x/f_x$ reduces $af_x f_{x+1} y_{x+z} + bf_x f_{x+2} y_{x+1} + cf_{x+1} f_{x+2} y_x = \phi(x)$ to an equation with constant coefficients.

Example $x(x+1)y_{x+2} + 3x(x+2)y_{x+1} - 4(x+1)(x+2)y_x = x$. Set $u_x = y_x/f_x = y_x/x$. Then $y_x = xu_x$, $y_{x+1} = (x+1)u_{x+1}$ and $y_{x+2} = (x+2)u_{x+2}$. Substitution in the equation yields $x(x+1)(x+2)u_{x+2} + 3x(x+2)(x+1)u_{u+1} - 4x(x+1)(x+2)$ $u_x = x$ or $u_{x+2} + 3u_{x+1} - 4u_x = 1/(x+1)(x+2)$, which is a linear equation with constant coefficients.

Nonlinear Difference Equations: Riccati Difference Equation The Riccati equation $y_{x+1}y_x + ay_{x+1} + by_x + c = 0$ is a nonlinear difference equation which can be solved by reduction to linear form. Set $y = z + h$. The equation becomes $z_{x+1}z_x + (h+a)z_{x+1} + (h+b)z_x + h^2 + (a+b)h + c = 0$. If h is selected as a root of $h^2 + (a+b)h + c = 0$ and the equation is divided by $z_{x+1}z_x$ there results $[(h+b)/z_{x+1}] + [(h+a)/z_x] + 1 = 0$. This is a linear equation with constant coefficients. The solution is

$$y_x = h + \cfrac{1}{c\left[-\dfrac{a+h}{b+h}\right]^x - \dfrac{1}{(a+h)+(b+h)}}$$

Example This equation is obtained in distillation problems, among others, in which the number of theoretical plates is required. If the relative volatility is assumed to be constant, the plates are theoretically perfect, and the molal liquid and vapor rates are constant, then a material balance around the nth plate of the enriching section yields a Riccati difference equation.

INTEGRAL EQUATIONS

References: Courant, R., and D. Hilbert, *Methods of Mathematical Physics,* vol. I, Interscience, New York (1953); Linz, P., *Analytical and Numerical Methods for Volterra Equations,* SIAM Publications, Philadelphia (1985); Porter, D., and D. S. G. Stirling, *Integral Equations: A Practical Treatment from Spectral Theory to Applications,* Cambridge University Press (1990); Statgold, I., *Green's Functions and Boundary Value Problems,* 2d ed., Interscience, New York (1997).

An integral equation is any equation in which the unknown function appears under the sign of integration and possibly outside the sign of integration. If derivatives of the dependent variable appear elsewhere in the equation, the equation is said to be integrodifferential.

CLASSIFICATION OF INTEGRAL EQUATIONS

Volterra integral equations have an integral with a variable limit. The Volterra equation of the second kind is

$$u(x) = f(x) + \lambda \int_a^x K(x, t)u(t)\, dt$$

whereas a Volterra equation of the first kind is

$$u(x) = \lambda \int_a^x K(x, t)u(t)\, dt$$

Equations of the first kind are very sensitive to solution errors so that they present severe numerical problems. Volterra equations are similar to initial value problems.

A Fredholm equation of the second kind is

$$u(x) = f(x) + \lambda \int_a^b K(x, t)u(t)\, dt$$

whereas a Fredholm equation of the first kind is

$$u(x) = \int_a^b K(x, t)u(t)\, dt$$

The limits of integration are fixed, and these problems are analogous to boundary value problems.

An eigenvalue problem is a homogeneous equation of the second kind, and solutions exist only for certain λ.

$$u(x) = \lambda \int_a^b K(x, t)u(t)\, dt$$

See Linz (1985) for further information and existence proofs.

If the unknown function u appears in the equation in any way except to the first power, the integral equation is said to be nonlinear. The equation $u(x) = f(x) + \int_a^b K(x, t)[u(t)]^{3/2}\, dt$ is nonlinear. The differential equation $du/dx = g(x, u)$ is equivalent to the nonlinear integral equation $u(x) = c + \int_a^x g[t, u(t)]\, dt$.

An integral equation is said to be singular when either one or both of the limits of integration become infinite or if $K(x, t)$ becomes infinite for one or more points of the interval under discussion.

Example $u(x) = x + \int_0^\infty \cos(xt)u(t)\, dt$ and $f(x) = \int_0^x \frac{u(t)}{x-t}\, dt$ are both singular. The kernel of the first equation is $\cos(xt)$, and that of the second is $(x-t)^{-1}$.

RELATION TO DIFFERENTIAL EQUATIONS

The Leibniz rule (see "Integral Calculus") can be used to show the equivalence of the initial-value problem consisting of the second-order differential equation $d^2y/dx^2 + A(x)(dy/dx) + B(x)y = f(x)$ together with the prescribed initial conditions $y(a) = y_0$, $y'(a) = y'_0$ to the integral equation.

$$y(x) = \int_a^x K(x, t)y(t)\, dt + F(x)$$

where $\quad K(x, t) = (t - x)[B(t) - A'(t)] - A(t)$

and $$F(x) = \int_a^x (x-t)f(t)\,dt + [A(a)y_0 + y_0'](x-a) + y_0$$

This integral equation is a **Volterra equation** of the second kind. Thus the initial-value problem is equivalent to a Volterra integral equation of the second kind.

Example $d^2y/dx^2 + x^2(dy/dx) + xy = x$, $y(0) = 1$, $y'(0) = 0$. Here $A(x) = x^2$, $B(x) = x$, $f(x) = x$. The equivalent integral equation is $y(x) = \int_0^x K(x, t)y(t)\,dt + F(x)$ where $K(x, t) = t(x - t) - t^2$ and $F(x) = \int_0^x (x - t)t\,dt + 1 = x^3/6 + 1$. Combining these $y(x) = \int_0^x t[x - 2t]y(t)\,dt + x^3/6 + 1$.

Eigenvalue problems can also be related. For example, the problem $(d^2y/dx^2) + \lambda y = 0$ with $y(0) = 0$, $y(a) = 0$ is equivalent to the integral equation $y(x) = \lambda \int_0^a K(x, t)y(t)\,dt$, where $K(x, t) = (t/a)(a - x)$ when $t < x$ and $K(x, t) = (x/a)(a - t)$ when $t > x$. The differential equation may be recovered from the integral equation by differentiating the integral equation by using the Leibniz rule.

METHODS OF SOLUTION

In general, the solution of integral equations is not easy, and a few exact and approximate methods are given here. Often numerical methods must be employed, as discussed in "Numerical Solution of Integral Equations."

Equations of Convolution Type The equation $u(x) = f(x) + \lambda \int_0^x K(x - t)u(t)\,dt$ is a special case of the linear integral equation of the second kind of Volterra type. The integral part is the convolution integral discussed under "Integral Transforms (Operational Methods)"; so the solution can be accomplished by Laplace transforms; $L[u(x)] = L[f(x)] + \lambda L[u(x)]L[K(x)]$ or

$$L[u(x)] = \frac{L[f(x)]}{1 - \lambda L[K(x)]}, \quad u(x) = L^{-1}\left[\frac{L[f(x)]}{1 - \lambda L[K(x)]}\right]$$

Equations of the type considered here occur quite frequently in practice in what can be called "cause-and-effect" systems.

Example In a certain linear system, the effect $E(t)$ due to a cause $C = \lambda E$ at time τ is a function only of the elapsed time $t - \tau$. If the system has the activity level 1 at time $t < 0$, the cause λE and effect (E) relation is given by the integral equation $E(t) = 1 + \lambda \int_0^t K(t - \tau)E(\tau)\,d\tau$. Let $K(t - \tau) = t - \tau$. Then $E(t) = 1 + \lambda \int_0^t (t - \tau)E(\tau)\,d\tau$. By using the transform method

$$E(t) = L^{-1}\left[\frac{L[1]}{1 - \lambda L[K(t)]}\right] = L^{-1}\left[\frac{1/p}{1 - \lambda/p^2}\right] = L^{-1}\left[\frac{p}{p^2 - \lambda}\right] = \cosh\sqrt{\lambda}\,t$$

Method of Successive Approximations Consider the equation $y(x) = f(x) + \lambda \int_a^b K(x, t)y(t)\,dt$. In this method a unique solution is obtained in sequence form as follows: Substitute in the right-hand member of the equation $y_0(t)$ for $y(t)$. Upon integration there results $y_1(t) = f(x) + \lambda \int_a^b K(x, t)y_0(t)\,dt$. Continue in like manner by replacing y_0 by y_1, y_1 by y_2, etc. A series of functions $y_0(x)$, $y_1(x)$, $y_2(x)$, . . . are obtained which satisfy the equations

$$y_n(x) = f(x) + \lambda \int_a^b K(x, t)y_{n-1}(t)\,dt$$

Then $y_n(x) = f(x) + \lambda \int_a^b K(x, t)f(t)\,dt + \lambda^2 \int_a^b K(x, t) \int_a^b K(t, t_1)f(t_1)\,dt_1\,dt + \lambda^3 \int_a^b K(x, t) \int_a^b K(t, t_1) \int_a^b K(t_1, t_2)f(t_2)\,dt_2\,dt_1\,dt + \cdots + R_n$, where R_n is the remainder, and

$$|R_n| \le |\lambda^n| \left(\begin{matrix}\text{max. } y_0 \\ a \le x \le b\end{matrix}\right) M^n(b - a)^n$$

where M = maximum value of $|K|$ in the rectangle $a \le t \le b$, $a \le x \le b$. If $|\lambda|M(b - a) < 1$, $\lim_{n\to\infty} R_n = 0$. Then $y_n(x) \to y(x)$, which is the unique solution.

INTEGRAL TRANSFORMS (OPERATIONAL METHODS)

References: Brown, J. W., and R. V. Churchill, *Fourier Series and Boundary Value Problems,* 6th ed., McGraw-Hill, New York (2000); Churchill, R. V., *Operational Mathematics,* 3d ed., McGraw-Hill, New York (1972); Davies, B., *Integral Transforms and Their Applications,* 3d ed., Springer (2002); Duffy, D. G., *Transform Methods for Solving Partial Differential Equations,* Chapman & Hall/CRC, New York (2004); Varma, A., and M. Morbidelli, *Mathematical Methods in Chemical Engineering,* Oxford, New York (1997).

The term "operational method" implies a procedure of solving differential and difference equations by which the boundary or initial conditions are automatically satisfied in the course of the solution. The technique offers a very powerful tool in the applications of mathematics, but it is limited to linear problems.

Most integral transforms are special cases of the equation $g(s) = \int_a^b f(t)K(s, t)\,dt$ in which $g(s)$ is said to be the transform of $f(t)$ and $K(s, t)$ is called the kernel of the transform. A tabulation of the more important kernels and the interval (a, b) of applicability follows. The first three transforms are considered here.

Name of transform	(a, b)	$K(s, t)$
Laplace	$(0, \infty)$	e^{-st}
Fourier	$(-\infty, \infty)$	$\frac{1}{\sqrt{2\pi}} e^{-ist}$
Fourier cosine	$(0, \infty)$	$\sqrt{\frac{2}{\pi}} \cos st$
Fourier sine	$(0, \infty)$	$\sqrt{\frac{2}{\pi}} \sin st$
Mellin	$(0, \infty)$	t^{s-1}
Hankel	$(0, \infty)$	$tJ_\nu(st)$, $\nu \ge -\frac{1}{2}$

LAPLACE TRANSFORM

The Laplace transform of a function $f(t)$ is defined by $F(s) = L\{f(t)\} = \int_0^\infty e^{-st}f(t)\,dt$, where s is a complex variable. Note that the transform is an improper integral and therefore may not exist for all continuous functions and all values of s. We restrict consideration to those values of s and those functions f for which this improper integral converges. The Laplace transform is used in process control (see Sec. 8).

The function $L[f(t)] = g(s)$ is called the direct transform, and $L^{-1}[g(s)] = f(t)$ is called the inverse transform. Both the direct and the inverse transforms are tabulated for many often-occurring functions. In general,

$$L^{-1}[g(s)] = \frac{1}{2\pi i} \int_{\alpha - i\infty}^{\alpha + i\infty} e^{st}g(s)\,ds$$

and to evaluate this integral requires a knowledge of complex variables, the theory of residues, and contour integration.

A function is said to be piecewise continuous on an interval if it has only a finite number of finite (or jump) discontinuities. A function f on $0 < t < \infty$ is said to be of exponential growth at infinity if there exist constants M and α such that $|f(t)| \le Me^{\alpha t}$ for sufficiently large t.

Sufficient Conditions for the Existence of Laplace Transform Suppose f is a function which is (1) piecewise continuous on every finite interval $0 < t < T$, (2) of exponential growth at infinity, and (3) $\int_0^\delta |f(t)|\,dt$ exist (finite) for every finite $\delta > 0$. Then the Laplace transform of f exists for all complex numbers s with sufficiently large real part.

Note that condition 3 is automatically satisfied if f is assumed to be piecewise continuous on every finite interval $0 \le t < T$. The function $f(t) = t^{-1/2}$ is not piecewise continuous on $0 \le t \le T$ but satisfies conditions 1 to 3.

Let Λ denote the class of all functions on $0 < t < \infty$ which satisfy conditions 1 to 3.

Example Let $f(t)$ be the Heaviside step function at $t = t_0$; i.e., $f(t) = 0$ for $t \le t_0$, and $f(t) = 1$ for $t > t_0$. Then

$$L\{f(t)\} = \int_{t_0}^{\infty} e^{-st}\, dt = \lim_{T\to\infty} \int_{t_0}^{T} e^{-st}\, dt = \lim_{T\to\infty} \frac{1}{s}\,(e^{-st_0} - e^{-sT}) = \frac{e^{-st_0}}{s}$$

provided $s > 0$.

Example Let $f(t) = e^{at}$, $t \ge 0$, where a is a real number. Then $L\{e^{at}\} = \int_0^\infty e^{-(s-a)}\, dt = 1/(s-a)$, provided Re $s > a$.

Properties of the Laplace Transform

1. The Laplace transform is a linear operator: $L\{af(t) + bg(t)\} = aL\{f(t)\} + bL\{g(t)\}$ for any constants a, b and any two functions f and g whose Laplace transforms exist.
2. The Laplace transform of a real-valued function is real for real s. If $f(t)$ is a complex-valued function, $f(t) = u(t) + iv(t)$, where u and v are real, then $L\{f(t)\} = L\{u(t)\} + iL\{v(t)\}$. Thus $L\{u(t)\}$ is the real part of $L\{f(t)\}$, and $L\{v(t)\}$ is the imaginary part of $L\{f(t)\}$.
3. The Laplace transform of a function in the class Λ has derivatives of all orders, and $L\{t^k f(t)\} = (-1)^k d^k F(s)/ds^k$, $k = 1, 2, 3, \ldots$.

Example $\int_0^\infty e^{-st} \sin at\, dt = \dfrac{a}{s^2+a^2}$, $s > 0$. By property 3, $\dfrac{2as}{(s^2+a^2)^2} = \int_0^\infty e^{-st}\, t \sin at\, dt = L\{t \sin at\}$.

Example By applying property 3 with $f(t) = 1$ and using the preceding results, we obtain

$$L\{t^k\} = (-1)^k \frac{d^k}{ds^k}\left(\frac{1}{s}\right) = \frac{k!}{s^{k+1}}$$

provided Re $s > 0$; $k = 1, 2, \ldots$. Similarly, we obtain

$$L\{t^k e^{at}\} = (-1)^k \frac{d^k}{ds^k}\left(\frac{1}{s-a}\right) = \frac{k!}{(s-a)^{k+1}}$$

4. Frequency-shift property (or, equivalently, the transform of an exponentially modulated function). If $F(s)$ is the Laplace transform of a function $f(t)$ in the class Λ, then for any constant a, $L\{e^{at} f(t)\} = F(s-a)$.

Example $L\{te^{-at}\} = \dfrac{1}{(s+a)^2}$, $s > 0$.

5. Time-shift property. Let $u(t-a)$ be the unit step function at $t = a$. Then $L\{f(t-a)u(t-a)\} = e^{-as}F(s)$.
6. Transform of a derivative. Let f be a differentiable function such that both f and f' belong to the class Λ. Then $L\{f'(t)\} = sF(s) - f(0)$.
7. Transform of a higher-order derivative. Let f be a function which has continuous derivatives up to order n on $(0, \infty)$, and suppose that f and its derivatives up to order n belong to the class Λ. Then $L\{f^{(j)}(t)\} = s^j F(s) - s^{j-1} f(0) - s^{j-2} f'(0) - \cdots - s f^{(j-2)}(0) - f^{(j-1)}(0)$ for $j = 1, 2, \ldots, k$.

Example

$$L\{f''(t)\} = s^2 L\{f(t)\} - sf(0) - f'(0)$$
$$L\{f'''(t)\} = s^3 L\{f(t)\} - s^2 f(0) - sf'(0) - f''(0)$$

Example Solve $y'' + y = 2e^t$, $y(0) = y'(0) = 2$. $L[y''] = -y'(0) - sy(0) + s^2 L[y] = -2 - 2s + s^2 L[y]$. Thus

$$-2 - 2s + s^2 L[y] + L[y] = 2L[e^t] = \frac{2}{s-1}$$

$$L[y] = \frac{2s^2}{(s-1)(s^2+1)} = \frac{1}{s-1} + \frac{s}{s^2+1} + \frac{1}{s^2+1}$$

Hence $y = e^t + \cos t + \sin t$.

A short table (Table 3-2) of very common Laplace transforms and inverse transforms follows. The references include more detailed tables. NOTE: $\Gamma(n+1) = \int_0^\infty x^n e^{-x}\, dx$ (gamma function); $J_n(t)$ = Bessel function of the first kind of order n.

8. $L\left[\int_a^t f(t)\, dt\right] = \dfrac{1}{s} L[f(t)] + \dfrac{1}{s}\int_a^0 f(t)\, dt$

TABLE 3-2 Laplace Transforms

$f(t)$	$g(s)$	$f(t)$	$g(s)$
1	$1/s$	$e^{-at}(1-at)$	$\dfrac{s}{(s+a)^2}$
t^n, (n a + integer)	$\dfrac{n!}{s^{n+1}}$	$\dfrac{t \sin at}{2a}$	$\dfrac{s}{(s^2+a^2)^2}$
t^n, $n \ne +$ integer	$\dfrac{\Gamma(n+1)}{s^{n+1}}$	$\dfrac{1}{2a^2} \sin at \sinh at$	$\dfrac{s}{s^4+4a^4}$
$\cos at$	$\dfrac{s}{s^2+a^2}$	$\cos at \cosh at$	$\dfrac{s^2}{s^4+4a^4}$
$\sin at$	$\dfrac{a}{s^2+a^2}$	$\dfrac{1}{2a}(\sinh at + \sin at)$	$\dfrac{s^2}{s^4-a^4}$
$\cosh at$	$\dfrac{s}{s^2-a^2}$	½ $(\cosh at + \cos at)$	$\dfrac{s^3}{s^4-a^4}$
$\sinh at$	$\dfrac{a}{s^2-a^2}$	$\dfrac{\sin at}{t}$	$\tan^{-1} \dfrac{a}{s}$
e^{-at}	$\dfrac{1}{s+a}$	$J_0(at)$	$\dfrac{1}{\sqrt{s^2+a^2}}$
$e^{-bt} \cos at$	$\dfrac{s+b}{(s+b)^2+a^2}$	$na^n \dfrac{J_n(at)}{t}$	$(\sqrt{s^2+a^2} - s)^n (n > 0)$
$e^{-bt} \sin at$	$\dfrac{a}{(s+b)^2+a^2}$	$J_0(2\sqrt{at})$	$\dfrac{1}{s} e^{-a/s}$
$\text{erfc} \dfrac{k}{2\sqrt{t}}$	$\dfrac{1}{s} e^{-k\sqrt{s}}$		

Example Find $f(t)$ if $L[f(t)] = \dfrac{1}{s^2}\left[\dfrac{1}{s^2-a^2}\right]$. $L\left[\dfrac{1}{a}\sinh at\right] = \dfrac{1}{s^2-a^2}$.

Therefore $f(t) = \int_0^t \left[\int_0^t \dfrac{1}{a}\sinh at\, dt\right] dt = \dfrac{1}{a^2}\left[\dfrac{\sinh at}{a} - t\right]$.

9. $L\left[\dfrac{f(t)}{t}\right] = \int_s^\infty g(s)\, ds \qquad L\left[\dfrac{f(t)}{t^k}\right] = \underbrace{\int_s^\infty \cdots \int_s^\infty}_{k \text{ integrals}} g(s)(ds)^k$

Example $L\left[\dfrac{\sin at}{t}\right] = \int_s^\infty L[\sin at]\, ds = \int_s^\infty \dfrac{a\, ds}{s^2+a^2} = \cot^{-1} \dfrac{s}{a}$

10. The unit step function

$$u(t-a) = \begin{cases} 0 & t < a \\ 1 & t > a \end{cases} \qquad L[u(t-a)] = e^{-as}/s$$

11. The unit impulse function is

$$\delta(a) = u'(t-a) = \begin{cases} \infty & \text{at } t = a \\ 0 & \text{elsewhere} \end{cases} \qquad L[u'(t-a)] = e^{-as}$$

12. $L^{-1}[e^{-as} g(s)] = f(t-a)u(t-a)$ (second shift theorem).
13. If $f(t)$ is periodic of period b, i.e., $f(t+b) = f(t)$, then

$$L[f(t)] = \left[\frac{1}{1-e^{-bs}}\right] \int_0^b e^{-st} f(t)\, dt$$

Example The partial differential equations relating gas composition to position and time in a gas chromatograph are $\partial y/\partial n + \partial x/\partial\theta = 0$, $\partial y/\partial n = x - y$, where $x = mx'$, $n = (k_G aP/G_m)h$, $\theta = (mk_G aP/\rho_B)t$ and G_M = molar velocity, y = mole fraction of the component in the gas phase, ρ_B = bulk density, h = distance from the entrance, P = pressure, k_G = mass-transfer coefficient, and m = slope of the equilibrium line. These equations are equivalent to $\partial^2 y/\partial n\, \partial\theta + \partial y/\partial n + \partial y/\partial\theta = 0$, where the boundary conditions considered here are $y(0, \theta) = 0$ and $x(n, 0) = y(n, 0) + (\partial y/\partial n)\ (n, 0) = \delta(0)$ (see property 11). The problem is conveniently

solved by using the Laplace transform of y with respect to n; write $g(s, \theta) = \int_0^\infty e^{-ns} y(n, \theta)\, dn$. Operating on the partial differential equation gives $s(dg/d\theta) - (\partial y/\partial\theta)(0, \theta) + sg - y(0, \theta) + dg/d\theta = 0$ or $(s + 1)(dg/d\theta) + sg = (\partial y/\partial\theta)(0, \theta) + y(0, \theta) = 0$. The second boundary condition gives $g(s, 0) + sg(s, 0) - y(0, 0) = 1$ or $g(s, 0) + sg(s, 0) = 1$ $(L[\delta(0)] = 1)$. A solution of the ordinary differential equation for g consistent with this second condition is

$$g(s, \theta) = \frac{1}{s + 1} e^{-s\theta/(s+1)}$$

Inversion of this transform gives the solution $y(n, \theta) = e^{-(n+\theta)} I_0(2\sqrt{n\theta})$ where I_0 = zero-order Bessel function of an imaginary argument. For large u, $I_n(u) \sim e^u/\sqrt{2\pi u}$. Hence for large n,

$$y(n, \theta) \sim \frac{\exp[-(\sqrt{\theta} - \sqrt{n})^2]}{2\pi^{1/2}(n\theta)^{1/4}}$$

or for sufficiently large n, the peak concentration occurs near $\theta = n$.

Other applications of Laplace transforms are given under "Differential Equations."

CONVOLUTION INTEGRAL

The convolution integral (faltung) of two functions $f(t)$, $r(t)$ is $x(t) = f(t)°r(t) = \int_0^t f(\tau)r(t - \tau)\, d\tau$.

Example $t° \sin t = \int_0^t \tau \sin(t - \tau)\, d\tau = t - \sin t.$

$$L[f(t)]L[h(t)] = L[f(t)°h(t)]$$

z-TRANSFORM

See Ogunnaike, Babatunde A., and W. Harmon Ray, *Process Dynamics, Modeling, and Control*, Oxford University Press (1994); Seborg, D., T. F. Edgar, and D. A. Mellichamp, *Process Dynamics and Control*, 2d ed., Wiley, New York (2003). The z-transform is useful when data is available at only discrete points. Let

$$f^*(t) = f(t_k)$$

be the value of f at the sample points

$$t_k = k\,\Delta t, \quad k = 0, 1, 2, \ldots$$

Then the function $f^*(t)$ is

$$f^*(t) = \sum_{k=0}^{\infty} f(t_k)\,\delta(t - t_k)$$

Take the Laplace transform of this.

$$g^*(s) = L[f^*(t)] = \sum_{k=0}^{\infty} f(t_k)\,e^{-st_k} = \sum_{k=0}^{\infty} f(t_k)\,e^{-s\Delta tk}$$

For convenience, replace $e^{s\Delta t}$ by z and call $g^*(z)$ the z-transform of $f^*(t)$.

$$g^*(z) = \sum_{k=0}^{\infty} f(t_k)\,z^{-k}$$

The z-transform is used in process control when the signals are at intervals of Δt. A brief table (Table 3-3) is provided here.

The z-transform can also be used to solve difference equations, just like the Laplace transform can be used to solve differential equations.

Example The difference equation for $y(k)$ is

$$y(k) + a_1 y(k - 1) + a_2 y(k - 2) = b_1 u(k)$$

Take the z-transform

$$(1 + a_1 z^{-1} + a_2 z^{-2})\,y^*(z) = b_1 u^*(z)$$

Then
$$y^*(z) = \frac{u^*(z)}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

The inverse transform must be found, usually from a table of inverse transforms.

TABLE 3-3 *z*-Transforms

$f(k)$	$g^*(z)$
$1(k)$	$\frac{1}{1 - z^{-1}}$
$k\,\Delta t$	$\frac{\Delta t\, z^{-1}}{(1 - z^{-1})^2}$
$(k\,\Delta t)^{n-1}$	$\lim_{a\to 0} (-1)^{n-1} \frac{\partial^{n-1}}{\partial a^{n-1}} \left(\frac{1}{1 - e^{-a\Delta t} z^{-1}}\right)$
$\sin a\,k\,\Delta t$	$\frac{z^{-1} \sin a\,\Delta t}{(1 - 2\,z^{-1} \cos a\,\Delta t + z^{-2})}$
$\cos a\,k\,\Delta t$	$\frac{1 - z^{-1} \cos a\,\Delta t}{(1 - 2\,z^{-1} \cos a\,\Delta t + z^{-2})}$
$e^{-ak\Delta t}$	$\frac{1}{1 - e^{-a\Delta t} z^{-1}}$
$e^{-bk\Delta t} \cos a\,k\,\Delta t$	$\frac{1 - z^{-1} e^{-b\Delta t} \cos a\,\Delta t}{1 - 2\,z^{-1} e^{-b\Delta t} \cos a\,\Delta t + z^{-2} e^{-2b\Delta t}}$
$\frac{1}{b} e^{-bk\Delta t} \sin a\,k\,\Delta t$	$\frac{1}{b} \frac{z^{-1} e^{-b\Delta t} \sin a\,\Delta t}{1 - 2\,z^{-1} e^{-b\Delta t} \cos a\,\Delta t + z^{-2} e^{-2b\Delta t}}$

FOURIER TRANSFORM

References: Bateman, H., *Tables of Integral Transforms*, vol. I, McGraw-Hill, New York (1954); Varma, A., and M. Morbidelli, *Mathematical Methods in Chemical Engineering*, Oxford, New York (1997).

The Fourier transform is given by

$$F[f(t)] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t) e^{-ist}\, dt = g(s)$$

and its inverse by

$$F^{-1}[g(s)] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(s) e^{ist}\, dt = f(t)$$

In brief, the condition for the Fourier transform to exist is that $\int_{-\infty}^{\infty} |f(t)|\, dt < \infty$, although certain functions may have a Fourier transform even if this is violated.

Example The function $f(t) = \begin{cases} 1 - a \le t \le a \\ 0 \text{ elsewhere} \end{cases}$ has $F[f(t)] = \int_{-a}^{a} e^{-ist}\, dt = \int_0^a e^{ist}\, dt + \int_0^a e^{-ist}\, dt = 2\int_0^a \cos st\, dt = \frac{2 \sin sa}{s}$

Properties of the Fourier Transform Let $F[f(t)] = g(s)$; $F^{-1}[g(s)] = f(t)$.

1. $F[f^{(n)}(t)] = (is)^n F[f(t)]$.
2. $F[af(t) + bh(t)] = aF[f(t)] + bF[h(t)]$.
3. $F[f(-t)] = g(-s)$.
4. $F[f(at)] = \frac{1}{a} g\left(\frac{s}{a}\right)$, $a > 0$.
5. $F[e^{-iwt} f(t)] = g(s + w)$.
6. $F[f(t + t_1)] = e^{ist_1} g(s)$.
7. $F[f(t)] = G(is) + G(-is)$ if $f(t) = f(-t)$ (f even)
   $F[f(t)] = G(is) - G(-is)$ if $f(t) = -f(-t)$ (f odd)

where $G(s) = L[f(t)]$. This result allows the use of the Laplace-transform tables to obtain the Fourier transforms.

Example Find $F[e^{-a|t|}]$ by property 7. $e^{-a|t|}$ is even. So $L[e^{-at}] = 1/(s + a)$. Therefore, $F[e^{-a|t|}] = 1/(is + a) + 1/(-is + a) = 2a/(s^2 + a^2)$.

FOURIER COSINE TRANSFORM

The Fourier cosine transform is given by

$$F_c[f(t)] = g(s) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(t) \cos st\, dt$$

and its inverse by

$$F_c^{-1}[g(s)] = f(t) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} g(s) \cos st \, ds$$

The Fourier sine transform F_s is obtainable by replacing the cosine by the sine in these integrals. They can be used to solve linear differential equations; see the transform references.

MATRIX ALGEBRA AND MATRIX COMPUTATIONS

MATRIX ALGEBRA

Matrices A rectangular array of mn quantities, arranged in m rows and n columns

$$A = (a_{ij}) = \begin{bmatrix} a_{11} & \dots & a_{1n} \\ a_{21} & \dots & a_{2n} \\ \vdots & & \\ a_{m1} & \dots & a_{mn} \end{bmatrix}$$

is called a matrix. The elements a_{ij} may be real or complex. The notation a_{ij} means the element in the ith row and jth column, i is called the row index, j the column index. If $m = n$ the matrix is said to be square and of order n. A matrix, even if it is square, does not have a numerical value, as a determinant does. However, if the matrix A is square, a determinant can be formed which has the same elements as the matrix A. This is called the determinant of the matrix and is written det (A) or $|A|$. If A is square and det $(A) \neq 0$, A is said to be nonsingular; if det $(A) = 0$, A is said to be singular. A matrix A has rank r if and only if it has a nonvanishing determinant of order r and no nonvanishing determinant of order $> r$.

Equality of Matrices Let $A = (a_{ij})$, $B = (b_{ij})$. Two matrices A and B are *equal* (=) if and only if they are identical; that is, they have the same number of rows and the same number of columns and equal corresponding elements ($a_{ij} = b_{ij}$ for all i and j).

Addition and Subtraction The operations of addition (+) and subtraction (−) of two or more matrices are possible if and only if they have the same number of rows and columns. Thus $A \pm B = (a_{ij} \pm b_{ij})$; i.e., addition and subtraction are of corresponding elements.

Transposition The matrix obtained from A by interchanging the rows and columns of A is called the transpose of A, written A' or A^T.

Example $A = \begin{bmatrix} 1 & 3 & 4 \\ 2 & 1 & 6 \end{bmatrix}, \quad A^T = \begin{bmatrix} 1 & 2 \\ 3 & 1 \\ 4 & 6 \end{bmatrix}$

Note that $(A^T)^T = A$.

Multiplication Let $A = (a_{ij})$, $i = 1, \dots, m_1$; $j = 1, \dots, m_2$. $B = (b_{ij})$, $i = 1, \dots, n_1$, $j = 1, \dots, n_2$. The product AB is defined if and only if the number of columns of A (m_2) equals the number of rows of $B(n_1)$, i.e., $n_1 = m_2$. For two such matrices the product $P = AB$ is defined by summing the element by element products of a row of A by a column of B. This is the row by column rule. Thus

$$p_{ij} = \sum_{k=1}^{n_1} a_{ik} b_{kj}$$

The resulting matrix has m_1 rows and n_2 columns.

Example $\begin{bmatrix} 3 & 2 \\ 1 & 1 \\ 5 & 4 \end{bmatrix} \begin{bmatrix} 0 & 1 & 5 & 6 \\ -2 & 0 & 1 & 3 \end{bmatrix} = \begin{bmatrix} -4 & 3 & 17 & 24 \\ -2 & 1 & 6 & 9 \\ -8 & 5 & 29 & 42 \end{bmatrix}$

It is helpful to remember that the element p_{ij} is formed from the ith row of the first matrix and the jth column of the second matrix. The matrix product is not commutative. That is, $AB \neq BA$ in general.

Inverse of a Matrix A square matrix A is said to have an inverse if there exists a matrix B such that $AB = BA = I$, where I is the identity matrix of order n.

$$\begin{bmatrix} 1 & 0 \dots & 0 \\ 0 & 1 \dots & \\ \vdots & & 1 \quad 0 \\ 0 & \dots 0 & 1 \end{bmatrix}$$

The inverse B is a square matrix of the order of A, designated by A^{-1}. Thus $AA^{-1} = A^{-1}A = I$. A square matrix A has an inverse if and only if A is nonsingular.

Certain relations are important:

(1) $(AB)^{-1} = B^{-1}A^{-1}$

(2) $(AB)^T = B^T A^T$

(3) $(A^{-1})^T = (A^T)^{-1}$

(4) $(ABC)^{-1} = C^{-1}B^{-1}A^{-1}$

Scalar Multiplication Let c be any real or complex number. Then $cA = (ca_{ij})$.

Adjugate Matrix of a Matrix Let A_{ij} denote the cofactor of the element a_{ij} in the determinant of the matrix A. The matrix B^T where $B = (A_{ij})$ is called the adjugate matrix of A written adj $A = B^T$. The elements b_{ij} are calculated by taking the matrix A, deleting the ith row and jth column, and calculating the determinant of the remaining matrix times $(-1)^{i+j}$. Then $A^{-1} = \text{adj } A/|A|$. This definition may be used to calculate A^{-1}. However, it is very laborious and the inversion is usually accomplished by numerical techniques shown under "Numerical Analysis and Approximate Methods."

Linear Equations in Matrix Form Every set of n nonhomogeneous linear equations in n unknowns

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ \vdots \qquad\qquad & \quad \vdots \\ a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n &= b_n \end{aligned}$$

can be written in matrix form as $AX = B$, where $A = (a_{ij})$, $X^T = [x_1 \cdots x_n]$, and $B^T = [b_1 \cdots b_n]$. The solution for the unknowns is $X = A^{-1}B$.

Special Square Matrices

1. A triangular matrix is a matrix all of whose elements above or below the main diagonal (set of elements $a_{11}, \dots, a_{nn}$) are zero.

If A is triangular, det $(A) = a_{11}. a_{22} \dots a_{nn}$.

2. A diagonal matrix is one such that all elements both above and below the main diagonal are zero (i.e., $a_{ij} = 0$ for all $i \neq j$). If all diagonal elements are equal, the matrix is called scalar. If A is diagonal, $A = (a_{ij})$, $A^{-1} = (1/a_{ij})$.
3. If $a_{ij} = a_{ji}$ for all i and j (i.e., $A = A^T$), the matrix is symmetric.
4. If $a_{ij} = -a_{ji}$ for $i \neq j$ but the a_{ij} are not all zero, the matrix is skew.
5. If $a_{ij} = -a_{ji}$ for all i and j (i.e., $a_{ii} = 0$), the matrix is skew symmetric.
6. If $A^T = A^{-1}$, the matrix A is orthogonal.
7. If the matrix $A^* = (\bar{a}_{ij})^T$, $\bar{a}_{ij}$ = complex conjugate of a_{ij}, A^* is the hermitian transpose of A.
8. If $A = A^{-1}$, A is involutory.
9. If $A = A^*$, A is hermitian.
10. If $A = -A^*$, A is skew hermitian.
11. If $A^{-1} = A^*$, A is unitary.

If A is any matrix, then AA^T and A^TA are square symmetric matrices, usually of different order.

Example Let $A = \begin{bmatrix} 5 & 1 & 3 & 0 \\ 3 & 4 & 1 & 5 \\ 2 & -2 & 0 & 1 \end{bmatrix}$, $A^T = \begin{bmatrix} 5 & 3 & 2 \\ 1 & 4 & -2 \\ 3 & 1 & 0 \\ 0 & 5 & 1 \end{bmatrix}$

$$AA^T = \begin{bmatrix} 35 & 22 & 8 \\ 22 & 51 & 3 \\ 8 & 3 & 9 \end{bmatrix}, \quad A^TA = \begin{bmatrix} 38 & 13 & 18 & 17 \\ 13 & 21 & 7 & 18 \\ 18 & 7 & 10 & 5 \\ 17 & 18 & 5 & 26 \end{bmatrix}$$

Using a program such as MATLAB, these are easily calculated.

Matrix Calculus

Differentiation Let the elements of $A = [a_{ij}(t)]$ be differentiable functions of t. Then $\dfrac{dA}{dt} = \left[\dfrac{da_{ij}(t)}{dt}\right]$.

Example $A = \begin{bmatrix} \sin t & \cos t \\ -\cos t & \sin t \end{bmatrix}, \dfrac{dA}{dt} = \begin{bmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{bmatrix}$.

Integration The integral $\int A\,dt = [\int a_{ij}(t)\,dt]$.

Example $A = \begin{bmatrix} t & 2 \\ t^2 & e^t \end{bmatrix}, \int A\,dt = \begin{bmatrix} t^2/2 & 2t \\ t^3/3 & e^t \end{bmatrix}$.

The matrix $B = A - \lambda I$ is called the characteristic (eigen) matrix of A. Here A is square of order n, λ is a scalar parameter, and I is the $n \times n$ identity. det B = det $(A - \lambda I) = 0$ is the characteristic (eigen) equation for A. The characteristic equation is always of the same degree as the order of A. The roots of the characteristic equation are called the eigenvalues of A.

Example $A = \begin{bmatrix} 1 & 2 \\ 3 & 8 \end{bmatrix}, B = \begin{bmatrix} 1 & 2 \\ 3 & 8 \end{bmatrix} - \begin{bmatrix} \lambda & 0 \\ 0 & \lambda \end{bmatrix} = \begin{bmatrix} 1-\lambda & 2 \\ 3 & 8-\lambda \end{bmatrix}$

is the characteristic matrix and $f(\lambda) = \det(B) = \det(A - \lambda I) = (1 - \lambda)(8 - \lambda) - 6 = 2 - 9\lambda + \lambda^2 = 0$ is the characteristic equation. The eigenvalues of A are the roots of $\lambda^2 - 9\lambda + 2 = 0$, which are $(9 \pm \sqrt{73})/2$.

A nonzero matrix X_i, which has one column and n rows, called a column vector satisfying the equation

$$(A - \lambda I)X_i = 0$$

and associated with the ith characteristic root λ_i is called an eigenvector.

Vector and Matrix Norms To carry out error analysis for approximate and iterative methods for the solutions of linear systems, one needs notions for vectors in R^n and for matrices that are analogous to the notion of length of a geometric vector. Let R^n denote the set of all vectors with n components, $x = (x_1, \ldots, x_n)$. In dealing with matrices it is convenient to treat vectors in R^n as columns, and so $x = (x_1, \ldots, x_n)^T$; however, we shall here write them simply as row vectors. A norm on R^n is a real-valued function f defined on R^n with the following properties:

1. $f(x) \geq 0$ for all $x \in R^n$.
2. $f(x) = 0$ if and only if $x = (0, 0, \ldots, 0)$.
3. $f(ax) = |a| f(x)$ for all real numbers a and $x \in R^n$.
4. $f(x + y) \leqq f(x) + f(y)$ for all $x, y \in R^n$.

The usual notation for a norm is $f(x) = \|x\|$.

The norm of a matrix is

$$\kappa(A) \equiv \|A\|\,\|A^{-1}\|$$

where $$\|A\| = \sup_{x \neq 0} \frac{\|A\,x\|}{\|x\|} = \max_k \sum_{j=1}^{n} |a_{jk}|$$

The norm is useful when doing numerical calculations. If the computer's floating-point precision is 10^{-6}, then $\kappa = 10^6$ indicates an ill-conditioned matrix. If the floating-point precision is 10^{-12} (double precision), then a matrix with $\kappa = 10^{12}$ may be ill-conditioned. Two other measures are useful and are more easily calculated:

$$\text{Ratio} = \frac{\max_k |a_{kk}^{(k)}|}{\min_k |a_{kk}^{(k)}|}, \quad V = \frac{|\det A|}{\alpha_1\,\alpha_2 \ldots \alpha_n}, \quad \alpha_i = (a_{i1}^2 + a_{i2}^2 + \cdots a_{in}^2)^{1/2}$$

where $a_{kk}^{(k)}$ are the diagonal elements of the LU decomposition.

MATRIX COMPUTATIONS

The principal topics in linear algebra involve systems of linear equations, matrices, vector spaces, linear transformations, eigenvalues and eigenvectors, and least-squares problems. The calculations are routinely done on a computer.

***LU* Factorization of a Matrix** To every $m \times n$ matrix A there exists a permutation matrix P, a lower triangular matrix L with unit diagonal elements, and an $m \times n$ (upper triangular) echelon matrix U such that $PA = LU$. The Gauss elimination is in essence an algorithm to determine U, P, and L. The permutation matrix P may be needed since it may be necessary in carrying out the Gauss elimination to interchange two rows of A to produce a (nonzero) pivot, such as if we start with

$$A = \begin{bmatrix} 0 & 2 \\ 1 & 6 \end{bmatrix}$$

If A is a square matrix and if principal submatrices of A are all nonsingular, then we may choose P as the identity in the preceding factorization and obtain $A = LU$. This factorization is unique if L is normalized (as assumed previously), so that it has unit elements on the main diagonal.

Solution of *Ax* = *b* by Using *LU* Factorization Suppose that the indicated system is compatible and that $A = LU$ (the case $PA = LU$ is similarly handled and amounts to rearranging the equations). Let $z = Ux$. Then $Ax = LUx = b$ implies that $Lz = b$. Thus to solve $Ax = b$ we first solve $Lz = b$ for z and then solve $Ux = z$ for x. This procedure does not require that A be invertible and can be used to determine all solutions of a compatible system $Ax = b$. Note that the systems $Lz = b$ and $Ux = z$ are both in triangular forms and thus can be easily solved.

The LU decomposition is essentially a Gaussian elimination, arranged for maximum efficiency. The chief reason for doing an LU decomposition is that it takes fewer multiplications than would be needed to find an inverse. Also, once the LU decomposition has been found, it is possible to solve for multiple right-hand sides with little increase in work. The multiplication count for an $n \times n$ matrix and m right-hand sides is

$$\text{operation count} = \frac{1}{3} n^3 - \frac{1}{3} n + mn^2$$

If an inverse is desired, it can be calculated by solving for the LU decomposition and then solving n problems with right-hand sides consisting of all zeros except one entry. Thus $4n^2/3 - n/3$ multiplications are required for the inverse. The determinant is given by

$$\text{Det}\,\mathbf{A} = \prod_{i=1}^{n} a_{ii}^{(i)}$$

where $a_{ii}^{(i)}$ are the diagonal elements obtained in the LU decomposition.

A tridiagonal matrix is one in which the only nonzero entries lie on the main diagonal and the diagonal just above and just below the main diagonal. The set of equations can be written as

$$a_i x_{i-1} + b_i x_i + c_i x_{i+1} = d_i$$

The LU decomposition is

$b_1 = b_1$

for k=2,n do

$$a'_k = \frac{a_k}{b'_{k-1}}, \quad b'_k = b_k - \frac{a_k}{b'_{k-1}} c_{k-1}$$

enddo

$d'_1 = d_1$

for k=2,n do

$d'_k = d_k - a'_k\,d'_{k-1}$

enddo

$x_n = d'_n/b'_n$

for k=n−1,1 do

$$x_k = \frac{d'_k - c_k\,x_{k+1}}{b'_k}$$

enddo

The operation count for an $n \times n$ matrix with m right-hand sides is

$$2(n-1)+m(3n-2)$$

If $$|b_i| > |a_i| + |c_i|$$

no pivoting is necessary, and this is true for many boundary-value problems and partial-differential equations.

Sparse matrices are ones in which the majority of the elements are zero. If the structure of the matrix is exploited, the solution time on a computer is greatly reduced. See Duff, I. S., J. K. Reid, and A. M. Erisman (eds.), *Direct Methods for Sparse Matrices,* Clarendon Press, Oxford (1986); Saad, Y., *Iterative Methods for Sparse Linear Systems,* 2d ed., Society for Industrial and Applied Mathematics, Philadelphia (2003). The conjugate gradient method is one method for solving sparse matrix problems, since it only involves multiplication of a matrix times a vector. Thus the sparseness of the matrix is easy to exploit. The conjugate gradient method is an iterative method that converges for sure in n iterations where the matrix is an $n \times n$ matrix.

Matrix methods, in particular finding the rank of the matrix, can be used to find the number of independent reactions in a reaction set. If the stoichiometric numbers for the reactions and molecules are put in the form of a matrix, the rank of the matrix gives the number of independent reactions. See Amundson, N. R., *Mathematical Methods in Chemical Engineering,* Prentice-Hall, Englewood Cliffs, N.J. (1966, p. 50).

***QR* Factorization of a Matrix** If A is an $m \times n$ matrix with $m \geq n$, there exists an $m \times m$ unitary matrix $Q = [q_1, q_2, \ldots, q_m]$ and an $m \times n$ right triangular matrix R such that $A = QR$. The QR factorization is frequently used in the actual computations when the other transformations are unstable.

Singular-Value Decomposition If A is an $m \times n$ matrix with $m \geq n$ and rank $k \leq n$, consider the two following matrices.

$$AA^* \quad \text{and} \quad A^*A$$

An $m \times m$ unitary matrix U is formed from the eigenvectors $\mathbf{u}_i$ of the first matrix.

$$U = [\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_m]$$

An $n \times n$ unitary matrix V is formed from the eigenvectors v_i of the second matrix.

$$V = [\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n]$$

Then matrix A can be decomposed into

$$A = U\Sigma V^*$$

where Σ is a $k \times k$ diagonal matrix with diagonal elements $d_{ii} = \sigma_i > 0$ for $1 \leq i \leq k$. The eigenvalues of $\Sigma^*\Sigma$ are σ_i^2. The vectors u_i for $k+1 \leq i \leq m$ and v_i for $k+1 \leq i \leq n$ are eigenvectors associated with the eigenvalue zero; the eigenvalues for $1 \leq i \leq k$ are σ_i^2. The values of σ_i are called the singular values of matrix A. If A is real, then U and V are real and hence orthogonal matrices. The value of the singular-value decomposition comes when a process is represented by a linear transformation and the elements of A, a_{ij}, are the contribution to an output i for a particular variable as input variable j. The input may be the size of a disturbance, and the output is the gain [Seborg, D. E., T. F. Edgar, and D. A. Mellichamp, *Process Dynamics and Control,* 2d ed., Wiley, New York (2004)]. If the rank is less than n, not all the variables are independent and they cannot all be controlled. Furthermore, if the singular values are widely separated, the process is sensitive to small changes in the elements of the matrix, and the process will be difficult to control.

Example Consider the following example from Noble and Daniel [*Applied Linear Algebra,* Prentice-Hall (1987)] with the MATLAB commands to do the analysis. Define the following real matrix with $m = 3$ and $n = 2$ (whose rank $k = 1$).

```
>> a = [ 1 1
         2 2
         2 2 ]

>> a1 = a'*a
a1 = 9   9      %(n × n or 2 × 2)
     9   9
>> a2 = a*a'
a2 = 2   4   4      %(m × m or 3 × 3)
     4   8   8
     4   8   8
>> [v,d1]=eig(a1)
v = −0.7071   0.7071      %(n × n or 2 × 2)
     0.7071   0.7071
d1 =  0  0
      0  18
>> [u,d2]=eig(a2)
u =  0.8944   0.2981   0.3333      %(m × m or 3 × 3)
    −0.4472   0.5963   0.6667
     0       −0.7454   0.6667
d2 =  0  0  0
      0  0  0
      0  0 18
```

Thus, $\sigma_1^2 = 18$ and the eigenfunctions are the rows of v and u. The second column of v is associated with the eigenvalue $\sigma_1^2 = 18$, and the third column of u is associated with the eigenvalue $\sigma_1^2 = 18$.

If A is square and nonsingular, the vector $\mathbf{x}$ that minimizes

$$\|A\mathbf{x} - \mathbf{b}\| \tag{3-71}$$

is obtained by solving the linear equations

$$\mathbf{x} = A^{-1}\mathbf{b}$$

When A is not square, then the solution to

$$A\mathbf{x} = \mathbf{b}$$

is

$$\mathbf{x} = V\mathbf{y}$$

where $y_i = b'_i/\sigma_i$ for $i = 1, \ldots, k$, $\mathbf{b'} = U^T\mathbf{b}$, and $y_{k+1}, y_{k+2}, \ldots, y_m$ are arbitrary. The matrices U and V are those obtained in the singular-value decomposition. The solution which minimizes the norm, Eq. (3-71), is $\mathbf{x}$ with $y_{k+1}, y_{k+2}, \ldots, y_m$ zero. These techniques can be used to monitor process variables. See Montgomery, D. C., *Introduction to Statistical Quality Control,* 4th ed., Wiley, New York (2001); Piovos, M. J., and K. A. Hoo, "Multivariate Statistics for Process Control," *IEEE Control Systems* **22**(5):8 (2002).

Principal Component Analysis (PCA) PCA is used to recognize patterns in data and reduce the dimensionality of the problem. Let the matrix A now represent data with the columns of A representing different samples and the rows representing different variables. The covariance matrix is defined as

$$\text{cov}(A) = \frac{A^TA}{m-1}$$

This is just the same matrix discussed with singular value decomposition. For data analysis, though, it is necessary to adjust the columns to have zero mean by subtracting from each entry in the column the average of the column entries. Once this is done, the *loadings* are the v_i and satisfy

$$\text{cov}(A)\,\mathbf{v}_i = \sigma_i^2\mathbf{v}_i$$

and the *score* vector $\mathbf{u}_i$ is given by

$$A\mathbf{v}_i = \sigma_i\mathbf{u}_i$$

In process analysis, the columns of A represent different measurement techniques (temperatures, pressures, etc.) and the rows represent the measurement output at different times. In that case

the columns of A are adjusted to have a zero mean and a variance of 1.0 (by dividing each entry in the column by the variance of the column). The goal is to represent the essential variation of the process with as few variables as possible. The $\mathbf{u}_i$, $\mathbf{v}_i$ pairs are arranged in descending order according to the associated σ_i. The σ_i can be thought of as the variance, and the $\mathbf{u}_i$, $\mathbf{v}_i$ pair captures the greatest amount of variation in the data. Instead of having to deal with n variables, one can capture most of the variation of the data by using only the first few pairs. An excellent example of this is given by Wise, B. M., and B. R. Kowalski, "Process Chemometrics," Chap. 8 in *Process Analytical Chemistry,* F. McLennan and B. Kowalski (eds.), Blackie Academic & Professional, London (1995). When modeling a slurry-fed ceramic melter, they were able to capture 97 percent of the variation by using only four eigenvalues and eigenvectors, even though there were 16 variables (columns) measured.

NUMERICAL APPROXIMATIONS TO SOME EXPRESSIONS

APPROXIMATION IDENTITIES

For the following relationships the sign ≅ means approximately equal to, when X is small. These equations are derived by using a Taylor's series (see "Series Summation and Identities").

Approximation	Approximation
$\frac{1}{1 \pm X} \cong 1 \mp X$	$\sqrt{1 \pm X} \cong 1 \pm \frac{X}{2}$

Approximation	Approximation
$(1 \pm X)^n \cong 1 \pm nX$	$(1 \pm X)^{-n} \cong 1 \mp nX$
$(a \pm X)^2 \cong a^2 \pm 2aX$	$e^x \cong 1 + X$
$\sin X \cong X (X \text{ rad})$	$\tan X \cong X$
$\sqrt{Y(Y+X)} \cong \frac{2Y+X}{2}$	$\sqrt{Y^2+X^2} \cong Y + \frac{X^2}{2Y} \left(\frac{X}{Y} \text{ small}\right)$

INTRODUCTION

The goal of approximate and numerical methods is to provide convenient techniques for obtaining useful information from mathematical formulations of physical problems. Often this mathematical statement is not solvable by analytical means. Or perhaps analytic solutions are available but in a form that is inconvenient for direct interpretation. In the first case it is necessary either to attempt to approximate the problem satisfactorily by one which will be amenable to analysis, to obtain an approximate solution to the original problem by numerical means, or to use the two techniques in combination.

Numerical techniques therefore do not yield exact results in the sense of the mathematician. Since most numerical calculations are inexact, the concept of error is an important feature. The error associated with an approximate value is defined as

$$\text{True value} = \text{approximate value} + \text{error}$$

The four sources of error are as follows:

1. *Gross errors.* These result from unpredictable human, mechanical, or electrical mistakes.
2. *Round-off errors.* These are the consequence of using a number specified by m correct digits to approximate a number which requires more than m digits for its exact specification. For example, approximate the irrational number $\sqrt{2}$ by 1.414. Such errors are often present in experimental data, in which case they may be called inherent errors, due either to empiricism or to the fact that the computer dictates the number of digits. Such errors may be especially damaging in areas such as matrix inversion or the numerical solution of partial differential equations when the number of algebraic operations is extremely large.
3. *Truncation errors.* These errors arise from the substitution of a finite number of steps for an infinite sequence of steps which would yield the exact result. To illustrate this error consider the infinite series for e^{-x}: $e^{-x} = 1 - x + x^2/2 - x^3/6 + E_T(x)$, where E_T is the truncation error, $E_T = (1/24)e^{-\varepsilon}x^4$, $0 < \varepsilon < x$. If x is positive, ε is also positive. Hence $e^{-\varepsilon} < 1$. The approximation $e^{-x} \approx 1 - x + x^2/2 - x^3/6$ is in error by a positive amount smaller than $(1/24)x^4$.
4. *Inherited errors.* These arise as a result of errors occurring in the previous steps of the computational algorithm.

The study of errors in a computation is related to the theory of probability. In what follows a relation for the error will be given in certain instances.

A variety of general-purpose computer programs are available commercially. Mathematica (http://www.wolfram.com/), Maple (http://www.maplesoft.com/), and Mathcad (http://www.mathcad.com/) all have the capability of doing symbolic manipulation so that algebraic solutions can be obtained. For example, Mathematica can solve some ordinary and partial differential equations analytically; Maple can make simple graphs and do linear algebra and simple computations; and Mathcad can do simple calculations. In this section, examples are given for the use of Matlab (http://www.mathworks.com/), which is a package of numerical analysis tools, some of which are accessed by simple commands and others of which are accessed by writing programs in C. Spreadsheets can also be used to solve certain problems, and these are described below too. A popular program used in chemical engineering education is Polymath (http://www.polymath-software.com/), which can numerically solve sets of linear or nonlinear equations, ordinary differential equations as initial-value problems, and perform data analysis and regression.

NUMERICAL SOLUTION OF LINEAR EQUATIONS

See the section entitled "Matrix Algebra and Matrix Computation."

NUMERICAL SOLUTION OF NONLINEAR EQUATIONS IN ONE VARIABLE

Special Methods for Polynomials Consider a polynomial equation of degree *n:*

$$P(x) = a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \cdots + a_{n-1}x + a_n = 0 \qquad (3\text{-}72)$$

with real coefficients. $P(x)$ has exactly n roots, which may be real or complex. If the roots are complex, they occur in pairs with their complex conjugates.

One can obtain an upper and lower bound for the real roots by the following device: If $a_0 > 0$ in Eq. (3-72) and if in Eq. (3-72) the first negative coefficient is preceded by k coefficients which are positive or zero, and if G is the greatest of the absolute values of the negative coefficients, then each real root is less than $1 + \sqrt[k]{G/a_0}$.

Example $P(x) = x^5 + 3x^4 - 7x^2 - 40x + 2 = 0$. Here $a_0 = 1$, $G = 40$, and $k = 3$ since we must supply 0 as the coefficient for x^3. Thus $1 + \sqrt[3]{40} \approx 4.42$ is an upper bound for the real roots. The largest real root is 2.19.

A lower bound to the real roots may be found by applying the criterion to the equation $P(-x)$.

Example $P(-x) = -x^5 + 3x^4 - 7x^2 + 40x + 2 = 0$, which is equivalent to $x^5 - 3x^4 + 7x^2 - 40x - 2 = 0$ since a_0 must be +. Then $a_0 = 1$, $G = 40$, and $k = 1$. Hence $-(1 + 40) = -41$ is a lower bound. The smallest real root is −3.41. Thus all real roots are between −41 and 4.42.

One last result is helpful in getting an estimate of how many positive and negative real roots there are.

Descartes Rule The number of positive real roots of a polynomial with real coefficients is either equal to the number of changes in sign v or is less than v by a positive even integer. The number of negative roots of $P(x)$ is either equal to the number of variations of sign of $P(-x)$ or is less than this by a positive even integer.

Example $f(x) = x^4 - 13x^2 + 4x - 2 = 0$ has three changes in sign; therefore, there are either three or one positive root. $f(-x) = x^4 - 13x^2 - 4x - 2$ has one change in sign. Therefore, there is one negative root. Using MATLAB, one defines the vector

$$C(i) = a_{i-1}$$

and uses the command roots(c) to find all the roots.

Methods for Nonlinear Equations in One Variable

Successive Substitutions Let $f(x) = 0$ be the nonlinear equation to be solved. If this is rewritten as $x = F(x)$, then an iterative scheme can be set up in the form $x_{k+1} = F(x_k)$. To start the iteration an initial guess must be obtained graphically or otherwise. The convergence or divergence of the procedure depends upon the method of writing $x = F(x)$, of which there will usually be several forms. However, if a is a root of $f(x) = 0$, and if $|F'(a)| < 1$, then for any initial approximation sufficiently close to a, the method converges to a. This process is called first order because the error in x_{k+1} is proportional to the first power of the error in x_k for large k.

One way of writing the equation is $x_{k+1} = x_k + \beta f(x_k)$. The choice of β is made such that $|1 + \beta\, df/dx(a)| < 1$. Convergence is guaranteed by the theorem given for simultaneous equations.

Methods of Perturbation Let $f(x) = 0$ be the equation. In general, the iterative relation is

$$x_{k+1} = x_k - [f(x_k)/\alpha_k]$$

where the iteration begins with x_0 as an initial approximation and α_k as some functional, derived below.

Newton-Raphson Procedure This variant chooses $\alpha_k = f'(x_k)$ where $f' = df/dx$ and geometrically consists of replacing the graph of $f(x)$ by the tangent line at $x = x_k$ in each successive step. If $f'(x)$ and $f''(x)$ have the same sign throughout an interval $a \le x \le b$ containing the solution, with $f(a)$, $f(b)$ of opposite signs, then the process converges starting from any x_0 in the interval $a \le x \le b$. The process is second order.

Example $f(x) = x - 1 + \dfrac{(0.5)^x - 0.5}{0.3}$

$$f'(x) = 1 - 2.3105[0.5]^x$$

An approximate root (obtained graphically) is 2.

Step k	x_k	$f(x_k)$	$f'(x_k)$
0	2	0.1667	0.4224
1	1.6054	0.0342	0.2407
2	1.4632	0.0055	0.1620

Method of False Position This variant is commenced by finding x_0 and x_1 such that $f(x_0)$, $f(x_1)$ are of opposite signs. Then α_1 = slope of secant line joining $[x_0, f(x_0)]$ and $[x_1, f(x_1)]$ so that

$$x_2 = x_1 - \frac{x_1 - x_0}{f(x_1) - f(x_0)} f(x_1)$$

In each of the following steps α_k is the slope of the line joining $[x_k, f(x_k)]$ to the most recently determined point where $f(x_j)$ has the opposite sign from that of $f(x_k)$. This method is of first order. If one uses the most recently determined point (regardless of sign), the method is a secant method.

Method of Wegstein This is a variant of the method of successive substitutions which forces and/or accelerates convergence. The iterative procedure $x_{k+1} = F(x_k)$ is revised by setting $\hat{x}_{k+1} = F(x_k)$ and then taking $x_{k+1} = qx_k + (1 - q)\hat{x}_{k+1}$, where q is a suitably chosen number which may be taken as constant throughout or may be adjusted at each step. Wegstein found that suitable q's are:

Behavior of successive substitution process		Range of optimum q
Oscillatory convergence		$0 < q < ½$
Oscillatory divergence	without Wegstein	$½ < q < 1$
Monotonic convergence		$q < 0$
Monotonic divergence	without Wegstein	$1 < q$

At each step q may be calculated to give a locally optimum value by setting

$$q = \frac{\hat{x}_{k+1} - \hat{x}_k}{\hat{x}_{k+1} - 2\hat{x}_k + \hat{x}_{k-1}}$$

The Wegstein method is a secant method applied to $g(x) \equiv x - F(x)$. In Microsoft Excel, roots are found by using Goal Seek or Solver. Assign one cell to be x, put the equation for $f(x)$ in another cell, and let Goal Seek or Solver find the value of x that makes the equation cell zero. In MATLAB, the process is similar except that a function (m-file) is defined and the command fzero('f',x0) provides the solution x, starting from the initial guess $x0$.

METHODS FOR MULTIPLE NONLINEAR EQUATIONS

Method of Successive Substitutions Write a system of equations as

$$\alpha_i = f_i(\alpha), \quad \text{or } \alpha = \mathbf{f}(\alpha)$$

The following theorem guarantees convergence. Let α be the solution to $\alpha_i = f_i(\alpha)$. Assume that given $h > 0$, there exists a number $0 < \mu < 1$ such that

$$\sum_{j=1}^{n} \left|\frac{\partial f_i}{\partial x_j}\right| \le \mu \quad \text{for} \quad |x_i - \alpha_i| < h, \quad i = 1, \ldots, n$$

$$x_i^{k+1} = f_i(x_i^k)$$

Then $\qquad x_i^k \to \alpha_i$

as k increases [see Finlayson (2003)].

Newton-Raphson Method To solve the set of equations

$$F_i(x_1, x_2, \ldots, x_n) = 0, \quad \text{or } F_i(\{x_j\}) = 0, \quad \text{or } F_i(\mathbf{x}) = 0$$

one uses a truncated Taylor series to give

$$0 = F_i(\{\mathbf{x}^k\}) + \sum_{j=1}^{n} \left.\frac{\partial F_i}{\partial x_j}\right|_{\mathbf{x}^k} (x_j^{k+1} - x_j^k)$$

Thus one solves iteratively from one point to another.

$$\sum_{j=1}^{n} A_{ij}^k (x_j^{k+1} - x_j^k) = -F_i(\{\mathbf{x}^k\})$$

where $$A_{ij}^k = \left.\frac{\partial F_i}{\partial x_j}\right|_{\mathbf{x}^k}$$

This method requires solution of sets of linear equations until the functions are zero to some tolerance or the changes of the solution between iterations is small enough. Convergence is guaranteed provided the norm of the matrix **A** is bounded, $\mathbf{F}(\mathbf{x})$ is bounded for the initial guess, and the second derivative of $\mathbf{F}(\mathbf{x})$ with respect to all variables is bounded. See Finlayson (2003).

Method of Continuity (Homotopy) In the case of n equations in n unknowns, when n is large, determining the approximate solution may involve considerable effort. In such a case the method of continuity is admirably suited for use on digital computers. It consists basically of the introduction of an extra variable into the n equations

$$f_i(x_1, x_2, \ldots, x_n) = 0 \qquad i = 1, \ldots, n \tag{3-73}$$

and replacing them by

$$f_i(x_1, x_2, \ldots, x_n, \lambda) = 0 \qquad i = 1, \ldots, n \tag{3-74}$$

where λ is introduced in such a way that the functions (3-74) depend in a simple way upon λ and reduce to an easily solvable system for $\lambda = 0$ and to the original equations (3-73) for $\lambda = 1$. A system of ordinary differential equations, with independent variable λ, is then constructed by differentiating Eqs. (3-74) with respect to λ. There results

$$\sum_{j=1}^{n} \frac{\partial f_i}{\partial x_j} \frac{dx_j}{d\lambda} + \frac{\partial f_i}{\partial \lambda} = 0 \tag{3-75}$$

where $x_1, \ldots, x_n$ are considered as functions of λ. Equations (3-75) are integrated, with initial conditions obtained from Eqs. (3-74) with $\lambda = 0$, from $\lambda = 0$ to $\lambda = 1$. If the solution can be continued to $\lambda = 1$, the values of $x_1, \ldots, x_n$ for $\lambda = 1$ will be a solution of the original equations. If the integration becomes infinite, the parameter λ must be introduced in a different fashion. Integration of the differential equations (which are usually nonlinear in λ) may be accomplished by using techniques described under "Numerical Solution of Ordinary Differential Equations."

Other Methods Other methods can be found in the literature. See Chan, T. F. C., and H. B. Keller, *SIAM J. Sci. Stat. Comput.* **3:**173–194 (1982); Seader, J. D., "Computer Modeling of Chemical Processes," *AIChE Monograph Series* **81**(15) (1986).

INTERPOLATION AND FINITE DIFFERENCES

Linear Interpolation If a function $f(x)$ is approximately linear in a certain range, then the ratio

$$\frac{f(x_1) - f(x_0)}{x_1 - x_0} = f[x_0, x_1]$$

is approximately independent of x_0, x_1 in the range. The linear approximation to the function $f(x)$, $x_0 < x < x_1$ then leads to the interpolation formula

$$\begin{aligned} f(x) &\approx f(x_0) + (x - x_0) f[x_0, x_1] \\ &\approx f(x_0) + \frac{x - x_0}{x_1 - x_0}[f(x_1) - f(x_0)] \\ &\approx \frac{1}{x_1 - x_0}[(x_1 - x)f(x_0) - (x_0 - x)f(x_1)] \end{aligned}$$

Divided Differences of Higher Order and Higher-Order Interpolation The first-order divided difference $f[x_0, x_1]$ was defined previously. Divided differences of second and higher order are defined iteratively by

$$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$

$$\vdots$$

$$f[x_0, x_1, \ldots, x_k] = \frac{f[x_1, \ldots, x_k] - f[x_0, x_1, \ldots, x_{k-1}]}{x_k - x_0}$$

and a convenient form for computational purposes is

$$f[x_0, x_1, \ldots, x_k] = \sum_{j=0}^{k}{}' \frac{f(x_j)}{(x_j - x_0)(x_j - x_1) \cdots (x_j - x_k)}$$

for any $k \geq 0$, where the $'$ means that the term $(x_j - x_j)$ is omitted in the denominator. For example,

$$f[x_0, x_1, x_2] = \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2)} + \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2)} + \frac{f(x_2)}{(x_2 - x_0)(x_2 - x_1)}$$

If the accuracy afforded by a linear approximation is inadequate, a generally more accurate result may be based upon the assumption that $f(x)$ may be approximated by a polynomial of degree 2 or higher over certain ranges. This assumption leads to Newton's fundamental interpolation formula with divided differences

$$\begin{aligned} f(x) \approx{}& f(x_0) + (x - x_0) f[x_0, x_1] + (x - x_0)(x - x_1) f[x_0, x_1, x_2] \\ &+ \cdots + (x - x_0)(x - x_1) \cdots (x - x_{n-1}) f[x_0, x_1, \ldots, x_n] + E_n(x) \end{aligned}$$

where $$E_n(x) = \text{error} = \frac{1}{(n+1)!} f^{n+1}(\varepsilon)\pi(x)$$

where minimum $(x_0, \ldots, x) < \varepsilon <$ maximum $(x_0, x_1, \ldots, x_n, x)$ and $\pi(x) = (x - x_0)(x - x_1) \cdots (x - x_n)$. In order to use the previous equation most effectively one may first form a divided-difference table. For example, for third-order interpolation the difference table is

x_0	$f(x_0)$			
		$f[x_0, x_1]$		
x_1	$f(x_1)$		$f[x_0, x_1, x_2]$	
		$f[x_1, x_2]$		$f[x_0, x_1, x_2, x_3]$
x_2	$f(x_2)$		$f[x_1, x_2, x_3]$	
		$f[x_2, x_3]$		
x_3	$f(x_3)$			

where each entry is given by taking the difference between diagonally adjacent entries to the left, divided by the abscissas corresponding to the ordinates intercepted by the diagonals passing through the calculated entry.

Equally Spaced Forward Differences If the ordinates are *equally spaced*, i.e., $x_j - x_{j-1} = \Delta x$ for all j, then the first differences are denoted by $\Delta f(x_0) = f(x_1) - f(x_0)$ or $\Delta y_0 = y_1 - y_0$, where $y = f(x)$. The differences of these first differences, called second differences, are denoted by $\Delta^2 y_0, \Delta^2 y_1, \ldots, \Delta^2 y_n$. Thus

$$\Delta^2 y_0 = \Delta y_1 - \Delta y_0 = y_2 - y_1 - y_1 + y_0 = y_2 - 2y_1 + y_0$$

And in general

$$\Delta^j y_0 = \sum_{n=0}^{j} (-1)^n \binom{j}{n} y_{j-n}$$

where $\binom{j}{n} = \frac{j!}{n!(j-n)!}$ = binomial coefficients.

If the ordinates are equally spaced,

$$\begin{aligned} x_{n+1} - x_n &= \Delta x \\ y_n &= y(x_n) \end{aligned}$$

then the first and second differences are denoted by

$$\begin{aligned} \Delta y_n &= y_{n+1} - y_n \\ \Delta^2 y_n &= \Delta y_{n+1} - \Delta y_n = y_{n+2} - 2y_{n+1} + y_n \end{aligned}$$

A new variable is defined

$$\alpha = \frac{x_\alpha - x_0}{\Delta x}$$

and the finite interpolation formula through the points $y_0, y_1, \ldots, y_n$ is written as follows:

$$y_\alpha = y_0 + \alpha\,\Delta y_0 + \frac{\alpha\,(\alpha-1)}{2!}\,\Delta^2 y_0 + \cdots + \frac{\alpha\,(\alpha-1)\cdots(\alpha-n+1)}{n!}\,\Delta^n y_0 \qquad (3\text{-}76)$$

Keeping only the first two terms gives a straight line through (x_0, y_0)–(x_1, y_1); keeping the first three terms gives a quadratic function of position going through those points plus (x_2, y_2). The value $\alpha = 0$ gives $x = x_0$; $\alpha = 1$ gives $x = x_1$, and so on.

Equally Spaced Backward Differences Backward differences are defined by

$$\nabla y_n = y_n - y_{n-1}$$
$$\nabla^2 y_n = \nabla y_n - \nabla y_{n-1} = y_n - 2\,y_{n-1} + y_{n-2}$$

The interpolation polynomial of order n through the points $y_0, y_{-1}, \ldots, y_{-n}$ is

$$y_\alpha = y_0 + \alpha\,\nabla y_0 + \frac{\alpha\,(\alpha+1)}{2!}\,\nabla^2 y_0 + \cdots + \frac{\alpha\,(\alpha+1)\cdots(\alpha+n-1)}{n!}\,\nabla^n y_0$$

The value of $\alpha = 0$ gives $x = x_0$; $\alpha = -1$ gives $x = x_{-1}$, and so on. Alternatively, the interpolation polynomial of order n through the points $y_1, y_0, y_{-1}, \ldots, y_{-n}$ is

$$y_\alpha = y_1 + (\alpha-1)\,\nabla y_1 + \frac{\alpha\,(\alpha-1)}{2!}\,\nabla^2 y_1 \qquad (3\text{-}77)$$
$$+ \cdots + \frac{(\alpha-1)\,\alpha\,(\alpha+1)\cdots(\alpha+n-2)}{n!}\,\nabla^n y_1$$

Now $\alpha = 1$ gives $x = x_1$; $\alpha = 0$ gives $x = x_0$.

Central Differences The central difference denoted by

$$\delta f(x) = f\left(x + \frac{h}{2}\right) - f\left(x - \frac{h}{2}\right)$$
$$\delta^2 f(x) = \delta f\left(x + \frac{h}{2}\right) - \delta f\left(x - \frac{h}{2}\right) = f(x+h) - 2f(x) + f(x-h)$$
$$\delta^n f(x) = \delta^{n-1} f\left(x + \frac{h}{2}\right) - \delta^{n-1} f\left(x - \frac{h}{2}\right)$$

is useful for calculating at the interior points of tabulated data.

Lagrange Interpolation Formulas A global polynomial is defined over the entire region of space

$$P_m(x) = \sum_{j=0}^{m} c_j x^j$$

This polynomial is of degree m (highest power is x^m) and order $m + 1$ ($m + 1$ parameters $\{c_j\}$). If we are given a set of $m + 1$ points

$$y_1 = f(x_1),\ y_2 = f(x_2),\ \ldots,\ y_{m+1} = f(x_{m+1})$$

then Lagrange's formula gives a polynomial of degree m that goes through the $m + 1$ points:

$$P_m(x) = \frac{(x-x_2)\,(x-x_3)\cdots(x-x_{m+1})}{(x_1-x_2)\,(x_1-x_3)\cdots(x_1-x_{m+1})}\,y_1$$
$$+ \frac{(x-x_1)\,(x-x_3)\cdots(x-x_{m+1})}{(x_2-x_1)\,(x_2-x_3)\cdots(x_2-x_{m+1})}\,y_2 + \cdots$$
$$+ \frac{(x-x_1)\,(x-x_2)\cdots(x-x_{m+1})}{(x_{m+1}-x_1)\,(x_{m+1}-x_2)\cdots(x_{m+1}-x_m)}\,y_{m+1}$$

Note that each coefficient of y_j is a polynomial of degree m that vanishes at the points $\{x_j\}$ (except for one value of j) and takes the value of 1.0 at that point:

$$P_m(x_j) = y_j, \quad j = 1, 2, \ldots, m+1$$

If the function $f(x)$ is known, the error in the approximation is, per Anderson, E., et al., LAPACK Users' Guide, SIAM(1992),

$$|\text{error}(x)| \le \frac{|x_{m+1} - x_1|^{m+1}}{(m+2)!}\ \max_{x_1 \le x \le x_{m+1}} |f^{(m+2)}(x)|$$

The evaluation of $P_m(x)$ at a point other than at the defining points can be made with Neville's algorithm [Press et al. (1986)]. Let P_1 be the value at x of the unique function passing through the point (x_1, y_1); or $P_1 = y_1$. Let P_{12} be the value at x of the unique polynomial passing through the points x_1 and x_2. Likewise, $P_{ijk\ldots r}$ is the unique polynomial passing through the points $x_i, x_j, x_k, \ldots x_r$. Then use the table

x_1	$y_1 = P_1$			
		P_{12}		
x_2	$y_2 = P_2$		P_{123}	
		P_{23}		P_{1234}
x_3	$y_3 = P_3$		P_{234}	
		P_{34}		
x_4	$y_4 = P_4$			

These entries are defined using

$$P_{i(i+1)\cdots(i+m)} = \frac{(x - x_{i+m})\,P_{i(i+1)\cdots(i+m-1)} + (x_i - x)\,P_{(i+1)(i+2)\cdots(i+m)}}{x_i - x_{i+m}}$$

For example, consider P_{1234}. The terms on the right-hand side involve P_{123} and P_{234}. The "parents," P_{123} and P_{234}, already agree at points 2 and 3. Here $i = 1$, $m = 3$; thus, the parents agree at $x_{i+1}, \ldots, x_{i+m-1}$ already. The formula makes $P_{i(i+1)\cdots(i+m)}$ agree with the function at the additional points x_{i+m} and x_i. Thus, $P_{i(i+1)\cdots(i+m)}$ agrees with the function at all the points $\{x_i, x_{i+1}, \ldots x_{i+m}\}$.

Spline Functions Splines are functions that match given values at the points $x_1, \ldots, x_{NT}$ and have continuous derivatives up to some order at the knots, or the points $x_2, \ldots, x_{NT-1}$. Cubic splines are most common; see de Boor, C., *A Practical Guide to Splines,* Springer (1978). The function is represented by a cubic polynomial within each interval (x_i, x_{i+1}) and has continuous first and second derivatives at the knots. Two more conditions can be specified arbitrarily. These are usually the second derivatives at the two end points, which are commonly taken as zero; this gives the natural cubic splines.

Take $y_i = y(x_i)$ at each of the points x_i, and let $\Delta x_i = x_{i+1} - x_i$. Then, in the interval (x_i, x_{i+1}), the function is represented as a cubic polynomial.

$$C_i(x) = a_{0i} + a_{1i}x + a_{2i}x^2 + a_{3i}x^3$$

The interpolating function takes on specified values at the knots and has continuous first and second derivatives at the knots. Within the ith interval, the function is

$$C_i(x) = C_i(x_i) + C_i'(x_i)(x - x_i) + C_i''(x_i)\,\frac{(x - x_i)}{2\Delta x_i}$$
$$+ [C_i''(x_{i+1}) - C_i''(x_i)]\,\frac{(x - x_i)^3}{6\Delta x_i}$$

where $C_i(x_i) = y_i$. The second derivative $C_i''(x_i) = y_i''$ is found by solving the following tridiagonal system of equations:

$$y_{i-1}''\Delta x_{i-1} + y_i''\,2(\Delta x_{i-1} + \Delta x_i) + y_{i+1}''\Delta x_i = -6\left(\frac{y_i - y_{i-1}}{\Delta x_{i-1}} - \frac{y_{i+1} - y_i}{\Delta x_i}\right)$$

Since the continuity conditions apply only for $i = 2, \ldots, NT - 1$, we have only $NT - 2$ conditions for the NT values of y_i''. Two additional conditions are needed, and these are usually taken as the value of the second derivative at each end of the domain, y_1'', y_{NT}''. If these values are zero, we get the natural cubic splines; they can also be set to achieve some other purpose, such as making the first derivative match some desired condition at the two ends. With these values taken as zero in the natural cubic spline, we have a $NT - 2$ system of tridiagonal equations, which is easily solved. Once the second derivatives are

known at each of the knots, the first derivatives are given by

$$y'_i = \frac{y_{i+1} - y_i}{\Delta x_i} - y''_i \frac{\Delta x_i}{3} - y''_{i+1} \frac{\Delta x_i}{6}$$

The function itself is then known within each element.

NUMERICAL DIFFERENTIATION

Numerical differentiation should be avoided whenever possible, particularly when data are empirical and subject to appreciable observation errors. Errors in data can affect numerical derivatives quite strongly; i.e., differentiation is a roughening process. When such a calculation must be made, it is usually desirable first to smooth the data to a certain extent.

Use of Interpolation Formula If the data are given over equidistant values of the independent variable x, an interpolation formula such as the Newton formula [Eq. (3-76) or (3-77)] may be used and the resulting formula differentiated analytically. If the independent variable is not at equidistant values, then Lagrange's formulas must be used. By differentiating three-point Lagrange interpolation formulas the following differentiation formulas result for equally spaced tabular points:

Three-Point Formulas Let x_0, x_1, x_2 be the three points.

$$f'(x_0) = \frac{1}{2h}[-3f(x_0) + 4f(x_1) - f(x_2)] + \frac{h^2}{3} f'''(\varepsilon)$$

$$f'(x_1) = \frac{1}{2h}[-f(x_0) + f(x_2)] - \frac{h^2}{6} f'''(\varepsilon)$$

$$f'(x_2) = \frac{1}{2h}[f(x_0) - 4f(x_1) + 3f(x_2)] + \frac{h^2}{3} f'''(\varepsilon)$$

where the last term is an error term $\min_j x_j < \varepsilon < \max_j x_j$.

Smoothing Techniques These techniques involve the approximation of the tabular data by a least-squares fit of the data by using some known functional form, usually a polynomial (for the concept of least squares see "Statistics"). In place of approximating $f(x)$ by a single least-squares polynomial of degree n over the entire range of the tabulation, it is often desirable to replace each tabulated value by the value taken on by a least-squares polynomial of degree n relevant to a subrange of $2M + 1$ points centered, when possible, at the point for which the entry is to be modified. Thus each smoothed value replaces a tabulated value. Let $f_j = f(x_j)$ be the tabular points and y_j = smoothed values.

First-Degree Least Squares with Three Points

$$y_0 = \tfrac{1}{6}[5f_0 + 2f_1 - f_2]$$

$$y_1 = \tfrac{1}{3}[f_0 + f_1 + f_2]$$

$$y_2 = \tfrac{1}{6}[-f_0 + 2f_1 + 5f_2]$$

The derivatives at all the points are

$$f'_0 = f'_1 = f'_2 = \frac{1}{2}h\,[y_2 - y_1]$$

Second-Degree Least Squares with Five Points For five evenly spaced points x_{-2}, x_{-1}, x_0, x_1, and x_2 (separated by distance h) and their ordinates f_{-2}, f_{-1}, f_0, f_1, and f_2, assume a parabola is fit by least squares. Then the derivative at the center point is

$$f'_0 = 1/10h\,[-2f_{-2} - f_{-1} + f_1 + 2f_2]$$

The derivatives at the other points are

$$f'_{-2} = 1/70h\,[-54f_{-2} + 13f_{-1} + 40f_0 + 27f_1 - 26f_2]$$

$$f'_{-1} = 1/70h\,[-34f_{-2} + 3f_{-1} + 20f_0 + 17f_1 - 6f_2]$$

$$f'_1 = 1/70h\,[6f_{-2} - 17f_{-1} - 20f_0 - 3f_1 + 34f_2]$$

$$f'_2 = 1/70h\,[26f_{-2} - 27f_{-1} - 40f_0 - 13f_1 + 54f_2]$$

Numerical Derivatives The results given above can be used to obtain numerical derivatives when solving problems on the computer, in particular for the Newton-Raphson method and homotopy methods. Suppose one has a program, subroutine, or other function evaluation device that will calculate f given x. One can estimate the value of the first derivative at x_0 using

$$\left.\frac{df}{dx}\right|_{x_0} \approx \frac{f[x_0(1+\varepsilon)] - f[x_0]}{\varepsilon x_0}$$

(a first-order formula) or

$$\left.\frac{df}{dx}\right|_{x_0} \approx \frac{f[x_0(1+\varepsilon)] - f[x_0(1-\varepsilon)]}{2\varepsilon x_0}$$

(a second-order formula). The value of ε is important; a value of 10^{-6} is typical, but smaller or larger values may be necessary depending on the computer precision and the application. One must also be sure that the value of x_0 is not zero and use a different increment in that case.

NUMERICAL INTEGRATION (QUADRATURE)

A multitude of formulas have been developed to accomplish numerical integration, which consists of computing the value of a definite integral from a set of numerical values of the integrand.

Newton-Cotes Integration Formulas (Equally Spaced Ordinates) for Functions of One Variable The definite integral $\int_a^b f(x)\,dx$ is to be evaluated.

Trapezoidal Rule This formula consists of subdividing the interval $a \le x \le b$ into n subintervals a to $a + h$, $a + h$ to $a + 2h$, . . . and replacing the graph of $f(x)$ by the result of joining the ends of adjacent ordinates by line segments. If $f_j = f(x_j) = f(a + jh)$, $f_0 = f(a)$, $f_n = f(b)$, the integration formula is

$$\int_a^b f(x)\,dx = \frac{h}{2}[f_0 + 2f_1 + 2f_2 + \cdots + 2f_{n-1} + f_n] + E_n$$

where $$|E_n| = \frac{nh^3}{12}|f''(\varepsilon)| = \frac{(b-a)^3}{12n^2}|f''(\varepsilon)| \qquad a < \varepsilon < b$$

This procedure is not of high accuracy. However, if $f''(x)$ is continuous in $a < x < b$, the error goes to zero as $1/n^2$, $n \to \infty$.

Parabolic Rule (Simpson's Rule) This procedure consists of subdividing the interval $a < x < b$ into $n/2$ subintervals, each of length $2h$, where n is an *even* integer. By using the notation as above the integration formula is

$$\int_a^b f(x)\,dx = \frac{h}{3}[f_0 + 4f_1 + 2f_2 + 4f_3 + \cdots + 4f_{n-3} + 2f_{n-2} + 4f_{n-1} + f_n] + E_n$$

where $$|E_n| = \frac{nh^5}{180}|f^{(IV)}(\varepsilon)| = \frac{(b-a)^5}{180n^4}|f^{(IV)}(\varepsilon)| \qquad a < \varepsilon < b$$

This method approximates $f(x)$ by a parabola on each subinterval. This rule is generally more accurate than the trapezoidal rule. It is the most widely used integration formula.

Gaussian Quadrature Gaussian quadrature provides a highly accurate formula based on irregularly spaced points, but the integral needs to be transformed onto the interval 0 to 1.

$$x = a + (b-a)u, \quad dx = (b-a)du$$

$$\int_a^b f(x)\,dx = (b-a)\int_0^1 f(u)\,du$$

$$\int_0^1 f(u)\,du = \sum_{i=1}^{m} W_i f(u_i)$$

The quadrature is exact when f is a polynomial of degree $2m - 1$ in x. Because there are m weights and m Gauss points, we have $2m$ parameters that are chosen to exactly represent a polynomial of degree

$2m - 1$, which has $2m$ parameters. The Gauss points and weights are given in the table.

Gaussian Quadrature Points and Weights

m	u_i	W_i
2	0.21132 48654	0.50000 00000
	0.78867 51346	0.50000 00000
3	0.11270 16654	0.27777 77778
	0.50000 00000	0.44444 44445
	0.88729 83346	0.27777 77778
4	0.06943 18442	0.17392 74226
	0.33000 94783	0.32607 25774
	0.66999 05218	0.32607 25774

	0.23076 53450	0.23931 43353
	0.50000 00000	0.28444 44444
	0.76923 46551	0.23931 43353
	0.95308 99230	0.11846 34425

Example Calculate the value of the following integral.

$$I = \int_0^1 e^{-x} \sin x \, dx \tag{3-78}$$

Using the Gaussian quadrature formulas gives the following values for various values of m. Clearly, three internal points, requiring evaluation of the integrand at only three points, gives excellent results.

m	I
2	0.24609643062368
3	0.24583487736505
4	0.24583700444293
5	0.24583700700700

Romberg's Method Romberg's method uses extrapolation techniques to improve the answer [Press et al. (1986)]. If we let I_1 be the value of the integral obtained using interval size $h = \Delta x$, and I_2 be the value of I obtained when using interval size $h/2$, and I_0 the true value of I, then the error in a method is approximately h^m, or

$$I_1 \approx I_0 + ch^m$$

$$I_2 \approx I_0 + c\left(\frac{h}{2}\right)^m$$

Replacing the ≈ by an equality (an approximation) and solving for c and I_0 gives

$$I_0 = \frac{2^m I_2 - I_1}{2^m - 1}$$

This process can also be used to obtain $I_1, I_2, \ldots$, by halving h each time, and then calculating new estimates from each pair, calling them $J_1, J_2, \ldots$; that is, in the formula above, replace I_0 with J_1. The formulas are reapplied for each pair of J to obtain $K_1, K_2, \ldots$ The process continues until the required tolerance is obtained.

$$\begin{matrix} I_1 & I_2 & I_3 & I_4 \\ & J_1 & J_2 & J_3 \\ & & K_1 & K_2 \\ & & & L_1 \end{matrix}$$

Romberg's method is most useful for a low-order method (small m) because significant improvement is then possible.

Example Evaluate the same intergral (3-78) by using the trapezoid rule and then apply the Romberg method. Use 11, 21, 41, and 81 points with $m = 2$. To achieve six-digit accuracy, any result from J_2 through L_1 is suitable, even though the base results (I_1 through I_4) are not that accurate.

$I_1 = 0.24491148225216$	$I_2 = 0.24560560017077$	$I_3 = 0.24577915369183$	$I_4 = 0.24582254357310$
	$J_1 = 0.24583697281030$	$J_2 = 0.24583700486552$	$J_3 = 0.24583700686685$
		$K_1 = 0.24583701555059$	$K_2 = 0.24583700753396$
			$L_1 = 0.24583700486175$

Computer Methods These methods are easily programmed in a spreadsheet program such as Microsoft Excel. In MATLAB, the trapezoid rule can be calculated by using the command trapz(x,y), where x is a vector of x values x_i and y is a vector of values $y(x_i)$. Alternatively, use the commands

```
F = @(x) exp(-x).*sin(x)
Q = quad(F,0,1)
```

$I_1 = 0.24491148225216$	$I_2 = 0.24560560017077$	$I_3 = 0.24577915369183$	$I_4 = 0.24582254357310$
	$J_1 = 0.24583697281030$	$J_2 = 0.24583700486552$	$J_3 = 0.24583700686685$
		$K_1 = 0.24583701555059$	$K_2 = 0.24583700753396$
			$L_1 = 0.24583700486175$

Singularities When the integrand has singularities, a variety of techniques can be tried. The integral may be divided into one part that can be integrated analytically near the singularity and another part that is integrated numerically. Sometimes a change of argument allows analytical integration. Series expansion might be helpful, too. When the domain is infinite, it is possible to use Gauss-Legendre or Gauss-Hermite quadrature. Also a transformation can be made. For example, let $u = 1/x$ and then

$$\int_a^b f(x)\,dx = \int_{1/b}^{1/a} \frac{1}{u^2} f\left(\frac{1}{u}\right) du \qquad ab > 0$$

Two-Dimensional Formula Two-dimensional integrals can be calculated by breaking down the integral into one-dimensional integrals.

$$\int_a^b \int_{g_1(x)}^{g_2(x)} f(x, y)\,dx\,dy = \int_a^b G(x)\,dx$$

$$G(x) = \int_{g_1(x)}^{g_2(x)} f(x, y)\,dy$$

Gaussian quadrature can also be used in two dimensions, provided the integration is on a square or can be transformed to one. (Domain transformations might be used to convert the domain to a square.)

$$\int_0^1 \int_0^1 f(x, y)\,dx\,dy = \sum_{i=1}^{mx} W_{xi} \sum_{j=1}^{my} W_{yj} f(x_i, y_j)$$

NUMERICAL SOLUTION OF ORDINARY DIFFERENTIAL EQUATIONS AS INITIAL VALUE PROBLEMS

A differential equation for a function that depends on only one variable, often time, is called an ordinary differential equation. The general solution to the differential equation includes many possibilities; the boundary or initial conditions are needed to specify which of those are desired. If all conditions are at one point, then the problem is an initial value problem and can be integrated from that point on. If some of the conditions are available at one point and others at another point, then the ordinary differential equations become two-point boundary value problems, which are treated in the next section. Initial value problems as ordinary differential equations arise in control of lumped parameter models, transient models of stirred tank reactors, and in all models where there are no spatial gradients in the unknowns.

A higher-order differential equation

$$y^{(n)} + F(y^{(n-1)}, y^{(n-2)}, \ldots, y', y) = 0$$

with initial conditions

$$G_i(y^{(n-1)}(0), y^{(n-2)}(0), \ldots, y(0), y(0)) = 0, \quad i = 1, \ldots, n$$

can be converted into a set of first-order equations using

$$y_i \equiv y^{(i-1)} = \frac{d^{(i-1)}y}{dt^{(i-1)}} = \frac{d}{dt} y^{(i-2)} = \frac{dy_{i-1}}{dt}$$

The higher-order equation can be written as a set of first-order equations.

$$\frac{dy_1}{dt} = y_2$$

$$\frac{dy_2}{dt} = y_3$$
$$\frac{dy_3}{dt} = y_4$$
$$\cdots$$
$$\frac{dy_n}{dt} = -F(y_{n-1}, y_{n-2}, \ldots, y_2, y_1)$$

The initial conditions would have to be specified for variables $y_1(0), \ldots, y_n(0)$, or equivalently $y(0), \ldots, y^{(n-1)}(0)$. The set of equations is then written as

$$\frac{d\mathbf{y}}{dt} = \mathbf{f}(\mathbf{y}, t)$$

All the methods in this section are described for a single equation; the methods apply to multiple equations.

Euler's method is first-order.

$$y^{n+1} = y^n + \Delta t\, f(y^n)$$

and errors are proportional to Δt. The second-order Adams-Bashforth method is

$$y^{n+1} = y^n + \frac{\Delta t}{2}\,[3f(y^n) - f(y^{n-1})]$$

Errors are proportional to Δt^2, and high-order methods are available. Notice that the higher-order explicit methods require knowing the solution (or the right-hand side) evaluated at times in the past. Since these were calculated to get to the current time, this presents no problem except for starting the problem. Then it may be necessary to use Euler's method with a very small step size for several steps in order to generate starting values at a succession of time points. The error terms, order of the method, function evaluations per step, and stability limitations are listed in Finlayson (2003). The advantage of the high-order Adams-Bashforth method is that it uses only one function evaluation per step yet achieves high-order accuracy. The disadvantage is the necessity of using another method to start.

Runge-Kutta methods are explicit methods that use several function evaluations for each time step. Runge-Kutta methods are traditionally written for $f(t, y)$. The first-order Runge-Kutta method is Euler's method. A second-order Runge-Kutta method is

$$y^{n+1} = y^n + \frac{\Delta t}{2}\,[f^n + f(t^n + \Delta t, y^n + \Delta t\, f^n)]$$

while the midpoint scheme is also a second-order Runge-Kutta method.

$$y^{n+1} = y^n + \Delta t\, f\left(t^n + \frac{\Delta t}{2}, y^n + \frac{\Delta t}{2} f^n\right)$$

A popular fourth-order Runge-Kutta method is the Runge-Kutta-Feldberg formulas, which have the property that the method is fourth-order but achieves fifth-order accuracy. The popular integration package RKF45 is based on this method.

$$k_1 = \Delta t\, f(t^n, y^n)$$
$$k_2 = \Delta t\, f\left(t^n + \frac{\Delta t}{4}, y^n + \frac{k_1}{4}\right)$$
$$k_3 = \Delta t\, f\left(t^n + \frac{3}{8}\Delta t, y^n + \frac{3}{32}k_1 + \frac{9}{32}k_2\right)$$
$$k_4 = \Delta t\, f\left(t^n + \frac{12}{13}\Delta t, y^n + \frac{1932}{2197}k_1 - \frac{7200}{2197}k_2 + \frac{7296}{2197}k_3\right)$$
$$k_5 = \Delta t\, f\left(t^n + \Delta t, y^n + \frac{439}{216}k_1 - 8k_2 + \frac{3680}{513}k_3 - \frac{845}{4104}k_4\right)$$
$$k_6 = \Delta t\, f\left(t^n + \frac{\Delta t}{2}, y^n - \frac{8}{27}k_1 + 2k_2 - \frac{3544}{2565}k_3 + \frac{1859}{4104}k_4 - \frac{11}{40}k_5\right)$$

$$y^{n+1} = y^n + \frac{25}{216}k_1 + \frac{1408}{2565}k_3 + \frac{2197}{4104}k_4 - \frac{1}{5}k_5$$
$$z^{n+1} = y^n + \frac{16}{135}k_1 + \frac{6656}{12825}k_3 + \frac{28561}{56430}k_4 - \frac{9}{50}k_5 + \frac{2}{55}k_6$$

The value of $y^{n+1} - z^{n+1}$ is an estimate of the error in y^{n+1} and can be used in step-size control schemes.

Usually one would use a high-order method to achieve high accuracy. The Runge-Kutta-Feldberg method is popular because it is high order and does not require a starting method (as does an Adams-Bashforth method). However, it does require four function evaluations per time step, or four times as many as a fourth-order Adams-Bashforth method. For problems in which the function evaluations are a significant portion of the calculation time, this might be important. Given the speed and availability of desktop computers, the efficiency of the methods is most important only for very large problems that are going to be solved many times. For other problems, the most important criterion for choosing a method is probably the time the user spends setting up the problem.

The stability limits for the explicit methods are based on the largest eigenvalue of the linearized system of equations

$$\frac{dy_i}{dt} = \sum_{i=1}^{n} A_{ij}\, y_j, \quad A_{ij} = \left.\frac{\delta f_i}{\delta y_j}\right|_y$$

For linear problems, the eigenvalues do not change, so that the stability and oscillation limits must be satisfied for *every* eigenvalue of the matrix **A.** When solving nonlinear problems, the equations are linearized about the solution at the local time, and the analysis applies for small changes in time, after which a new analysis about the new solution must be made. Thus, for nonlinear problems, the eigenvalues keep changing, and the largest stable time step changes, too. The stability limits are:

Euler method, $\lambda\,\Delta t \le 2$

Runge-Kutta, 2nd order, $\lambda\,\Delta t < 2$

Runge-Kutta-Feldberg, $\lambda\,\Delta t < 3.0$

Richardson extrapolation can be used to improve the accuracy of a method. Suppose we step forward one step Δt with a pth-order method. Then redo the problem, this time stepping forward from the same initial point, but in two steps of length $\Delta t/2$, thus ending at the same point. Call the solution of the one-step calculation y_1 and the solution of the two-step calculation y_2. Then an improved solution at the new time is given by

$$y = \frac{2^p y_2 - y_1}{2^p - 1}$$

This gives a good estimate provided Δt is small enough that the method is truly convergent with order p. This process can also be repeated in the same way Romberg's method was used for quadrature.

The error term in the various methods can be used to deduce a step size that will give a user-specified accuracy. Most packages today are based on a user-specified tolerance; the step-size is changed during the calculation to achieve that accuracy. The accuracy itself is not guaranteed, but it improves as the tolerance is decreased.

Implicit Methods By using different interpolation formulas involving y^{n+1}, it is possible to derive implicit integration methods. Implicit methods result in a nonlinear equation to be solved for y^{n+1} so that iterative methods must be used. The backward Euler method is a first-order method.

$$y^{n+1} = y^n + \Delta t\, f(y^{n+1})$$

Errors are proportional to Δt for small Δt. The trapezoid rule is a second-order method.

$$y^{n+1} = y^n + \frac{\Delta t}{2}\,[f(y^n) + f(y^{n+1})]$$

Errors are proportional to Δt^2 for small Δt. When the trapezoid rule is used with the finite difference method for solving partial differential equations, it is called the Crank-Nicolson method. The implicit methods are stable for any step size but do require the solution of a set of nonlinear equations, which must be solved iteratively. The set of equations can be solved using the successive substitution method

or Newton-Raphson method. See Bogacki, M. B, K. Alejski, and J. Szymanewski, *Comp. Chem. Eng.* **13:** 1081–1085 (1989) for an application to dynamic distillation problems.

The best packages for stiff equations (see below) use Gear's backward difference formulas. The formulas of various orders are [Gear, G. W., *Numerical Initial Value Problems in Ordinary Differential Equations,* Prentice-Hall, Englewood Cliffs, N.J. (1971)]

$$(1)\ y^{n+1} = y^n + \Delta t\, f(y^{n+1})$$

$$(2)\ y^{n+1} = \frac{4}{3} y^n - \frac{1}{3} y^{n-1} + \frac{2}{3} \Delta t\, f(y^{n+1})$$

$$(3)\ y^{n+1} = \frac{18}{11} y^n - \frac{9}{11} y^{n-1} + \frac{2}{11} y^{n-2} + \frac{6}{11} \Delta t\, f(y^{n+1})$$

$$(4)\ y^{n+1} = \frac{48}{25} y^n - \frac{36}{25} y^{n-1} + \frac{16}{25} y^{n-2} - \frac{3}{25} y^{n-3} + \frac{12}{25} \Delta t\, f(y^{n+1})$$

$$(5)\ y^{n+1} = \frac{300}{137} y^n - \frac{300}{137} y^{n-1} + \frac{200}{137} y^{n-2} - \frac{75}{137} y^{n-3} + \frac{12}{137} y^{n-4} + \frac{60}{137} \Delta t\, f(y^{n+1})$$

Stiffness The concept of stiffness is described for a system of linear equations.

$$\frac{d\mathbf{y}}{dt} = \mathbf{Ay}$$

Let λ_i be the eigenvalues of the matrix **A**. The stiffness ratio is defined as

$$\text{SR} = \frac{\max_i |\text{Re}\,(\lambda_i)|}{\min_i |\text{Re}\,(\lambda_i)|} \tag{3-79}$$

SR = 20 is not stiff, SR = 10^3 is stiff, and SR = 10^6 is very stiff. If the problem is nonlinear, then the solution is expanded about the current state.

$$\frac{dy_i}{dt} = f_i\,[\mathbf{y}(t^n)] + \sum_{j=1}^{n} \frac{\partial f_i}{\partial y_j}\,[y_j - y_j(t^n)]$$

The question of stiffness then depends on the solution at the current time. Consequently nonlinear problems can be stiff during one time period and not stiff during another. While the chemical engineer may not actually calculate the eigenvalues, it is useful to know that they determine the stability and accuracy of the numerical scheme and the step size used.

Problems are stiff when the time constants for different phenomena have very different magnitudes. Consider flow through a packed bed reactor. The time constants for different phenomena are:

1. Time for device flow-through

$$t_{\text{flow}} = \frac{L}{u} = \frac{\phi AL}{Q}$$

where Q is the volumetric flow rate, A is the cross sectional area, L is the length of the packed bed, and ϕ is the void fraction;

2. Time for reaction

$$t_{r\times n} = \frac{1}{k}$$

where k is a rate constant (time^{-1});

3. Time for diffusion inside the catalyst

$$t_{\text{internal diffusion}} = \frac{\varepsilon R^2}{D_e}$$

where ε is the porosity of the catalyst, R is the catalyst radius, and D_e is the effective diffusion coefficient inside the catalyst;

4. Time for heat transfer is

$$t_{\text{internal heat transfer}} = \frac{R^2}{\alpha} = \frac{\rho_s C_s R^2}{k_e}$$

where ρ_s is the catalyst density, C_s is the catalyst heat capacity per unit mass, k_e is the effective thermal conductivity of the catalyst, and α is the thermal diffusivity. For example, in the model of a catalytic converter for an automobile [Ferguson, N. B., and B. A. Finlayson, *AIChE J.* **20:**539–550 (1974)], the time constants for internal diffusion was 0.3 seconds; internal heat transfer, 21 seconds; and device flow-through, 0.003 seconds. The device flow-through is so fast that it might as well be instantaneous. The stiffness is approximately 7000. Implicit methods must be used to integrate the equations. Alternatively, a quasistate model can be developed [Ramirez, W. F., *Computational Methods for Process Simulations,* 2d ed., Butterworth-Heinemann, Boston (1997)].

Differential-Algebraic Systems Sometimes models involve ordinary differential equations subject to some algebraic constraints. For example, the equations governing one equilibrium stage (as in a distillation column) are

$$M\frac{dx^n}{dt} = V^{n+1}y^{n+1} - L^n x^n - V^n y^n + L^{n-1}x^{n-1}$$

$$x^{n-1} - x^n = E^n(x^{n-1} - x^{*,n})$$

$$\sum_{i=1}^{N} x_i = 1$$

where x and y are the mole fraction in the liquid and vapor, respectively; L and V are liquid and vapor flow rates, respectively; M is the holdup; and the superscript is the stage number. The efficiency is E, and the concentration in equilibrium with the vapor is x^*. The first equation is an ordinary differential equation for the mass of one component on the stage, while the third equation represents a constraint that the mass fractions add to one. This is a differential-algebraic system of equations.

Differential-algebraic equations can be written in the general notation

$$F\left(t, y, \frac{dy}{dt}\right) = 0$$

To solve the general problem using the backward Euler method, replace the nonlinear differential equation with the nonlinear algebraic equation for one step.

$$F\left(t, y^{n+1}, \frac{y^{n+1} - y^n}{\Delta t}\right) = 0$$

This equation must be solved for y^{n+1}. The Newton-Raphson method can be used, and if convergence is not achieved within a few iterations, the time step can be reduced and the step repeated. In actuality, the higher-order backward-difference Gear methods are used in DASSL [Ascher, U. M., and L. R. Petzold, *Computer Methods for Ordinary Differential Equations and Differential-Algebraic Equations,* SIAM, Philadelphia (1998); and Brenan, K. E., S. L. Campbell, and L. R. Petzold, *Numerical Solution of Initial-Value Problems in Differential-Algebraic Equations,* North Holland: Elsevier (1989)].

Differential-algebraic systems are more complicated than differential systems because the solution may not always be defined. Pontelides et al. [*Comp. Chem. Eng.* **12:** 449–454 (1988)] introduced the term *index* to identify the possible problems. The index is defined as the minimum number of times the equations need to be differentiated with respect to time to convert the system to a set of ordinary differential equations. These higher derivatives may not exist, and the process places limits on which variables can be given initial values. Sometimes the initial values must be constrained by the algebraic equations. For a differential-algebraic system modeling a distillation tower, Pontelides et al. show that the index depends on the specification of pressure for the column. Byrne and Ponzi [*Comp. Chem. Eng.* **12:** 377–382 (1988); also Chan, T. F. C., and H. B. Keller, *SIAM J. Sci. Stat. Comput.* **3:** 173–194 (1982)] also list several chemical engineering examples of differential-algebraic systems and solve one involving two-phase flow.

Computer Software Efficient computer packages are available for solving ordinary differential equations as initial value problems. The packages are widely available and good enough that most chemical engineers use them and do not write their own. Here we discuss three of them: RKF45, LSODE, and EPISODE. In each of the packages, the user specifies the differential equation to be solved and a

desired error criterion. The package then integrates in time and adjusts the step size to achieve the error criterion within the limitations imposed by stability.

A popular explicit, Runge-Kutta package is RKF45. Notice there that an estimate of the truncation error at each step is available. Then the step size can be reduced until this estimate is below the user-specified tolerance. The method is thus automatic, and the user is assured of the results. Note, however, that the tolerance is set on the local truncation error, namely from one step to another, whereas the user is usually interested in the global truncation error, or the error after several steps. The global error is generally made smaller by making the tolerance smaller, but the absolute accuracy is not the same as the tolerance. If the problem is stiff, then very small step sizes are used; the computation becomes very lengthy. The RKF45 code discovers this and returns control to the user with a message indicating the problem is too hard to solve with RKF45.

A popular implicit package is LSODE, a version of Gear's method (Gear, ibid.) written by Alan Hindmarsh at Lawrence Livermore Laboratory. In this package, the user specifies the differential equation to be solved and the tolerance desired. Now the method is implicit and therefore stable for any step size. The accuracy may not be acceptable, however, and sets of nonlinear equations must be solved. Thus, in practice the step size is limited but not nearly so much as in the Runge-Kutta methods. In these packages, both the step size and order of the method are adjusted by the package. Suppose we are calculating with a kth order method. The truncation error is determined by the $(k+1)$th order derivative. This is estimated using difference formulas and the values of the right-hand sides at previous times. An estimate is also made for the kth and $(k+2)$th derivative. Then it is possible to estimate the error in a $(k-1)$th order method, a kth order method, and a $(k+1)$th order method. Furthermore, the step size needed to satisfy the tolerance with each of these methods can be determined. Then we can choose the method and step size for the next step that achieves the biggest step, with appropriate adjustments due to the different work required for each order. The package generally starts with a very small step size and a first-order method, the backward Euler method. Then it integrates along, adjusting the order up (and later down) depending on the error estimates. The user is thus assured that the local truncation error meets the tolerance. There is a further difficulty, since the set of nonlinear equations must be solved. Usually a good guess of the solution is available, since the solution is evolving in time and past history can be extrapolated. Thus, the Newton-Raphson method will usually converge. The package protects itself, though, by only doing a few iterations. If convergence is not reached within this many iterations, then the step size is reduced and the calculation is redone for that time step. The convergence theorem for the Newton-Raphson method (p. 3-50) indicates that the method will converge if the step size is small enough. Thus the method is guaranteed to work. Further economies are possible. The Jacobian needed in the Newton-Raphson method can be fixed over several time steps. Then, if the iteration does not converge, the Jacobian can be reevaluated at the current time-step. If the iteration still does not converge, then the step-size is reduced and a new Jacobian is evaluated. Also the successive substitution method can be used, which is even faster, except that it may not converge. However, it, too, will converge if the time step is small enough.

The Runge-Kutta methods give extremely good accuracy, especially when the step size is kept small for stability reasons. If the problem is stiff, though, backward difference implicit methods must be used. Many chemical reactor problems are stiff, necessitating the use of implicit methods. In the MATLAB suite of ODE solvers, the ode45 uses a revision of the RKF45 program, while the ode15s program uses an improved backward difference method. Shampine and Reichelt [*SIAM J. Sci. Comp*. **18:**1–22 (1997)] give details of the programs in MATLAB. Fortunately, many packages are available. On the NIST web page http://gams.nist.gov/, choose "problem decision tree" and then "differential and integral equations" to find packages that can be downloaded. On the Netlib web site http://www.netlib.org/, choose "ode" to find packages that can be downloaded. Using Microsoft Excel to solve ordinary differential equations is cumbersome, except for the simplest problems.

Stability, Bifurcations, Limit Cycles Some aspects of this subject involve the solution of nonlinear equations; other aspects involve the integration of ordinary differential equations; applications include chaos and fractals as well as unusual operation of some chemical engineering equipment. Kubicek, M., and M. Marek, *Computational Methods in Bifurcation Theory and Dissipative Structures*, Springer-Verlag, Berlin (1983), give an excellent introduction to the subject and the details needed to apply the methods. Chan, T. F. C., and H. B. Keller, *SIAM J. Sci. Stat. Comput*. **3:**173–194 (1982), give more details of the algorithms. A concise survey with some chemical engineering examples is given in Doherty, M. F., and J. M. Ottino, *Chem. Eng. Sci*. **43:**139–183 (1988). Bifurcation results are closely connected with stability of the steady states, which is essentially a transient phenomenon.

Sensitivity Analysis When solving differential equations, it is frequently necessary to know the solution as well as the sensitivity of the solution to the value of a parameter. Such information is useful when doing parameter estimation (to find the best set of parameters for a model) and for deciding if a parameter needs to be measured accurately. See Finlayson, et al. (2006).

Molecular Dynamics Special integration methods have been developed for molecular dynamics calculations due to the structure of the equations. A very large number of equations are to be integrated, with the following form based on molecular interactions between molecules.

$$m_i \frac{d^2\mathbf{r}_i}{dt^2} = \mathbf{F}_i(\{\mathbf{r}\}) \quad \mathbf{F}_i(\{\mathbf{r}\}) = -\nabla V$$

The symbol m_i is the mass of the ith particle, $\mathbf{r}_i$ is the position of the ith particle, $\mathbf{F}_i$ is the force acting on the ith particle, and V is the potential energy that depends upon the location of all the particles (but not their velocities). Since the major part of the calculation lies in the evaluation of the forces, or potentials, a method must be used that minimizes the number of times the forces are calculated to move from one time to another time. Rewrite this equation in the form of an acceleration as

$$\frac{d^2\mathbf{r}_i}{dt^2} = \frac{1}{m_i}\mathbf{F}_i(\{\mathbf{r}\}) \equiv \mathbf{a}_i$$

In the Verlet method, this equation is written by using central finite differences (see "Interpolation and Finite Differences"). Note that the accelerations do not depend upon the velocities.

$$\mathbf{r}_i(t+\Delta t) = 2\mathbf{r}_i(t) - \mathbf{r}_i(t-\Delta t) + \mathbf{a}_i(t)\Delta t^2$$

The calculations are straightforward, and no explicit velocity is needed. The storage requirement is modest, and the precision is modest (it is a second-order method). Note that one must start the calculation with values of $\{\mathbf{r}\}$ at times t and $t - \Delta t$.

In the Verlet velocity method, an equation is written for the velocity, too.

$$\frac{d\mathbf{v}_i}{dt} = \mathbf{a}_i$$

The trapezoid rule [see "Numerical Integration (Quadrature)"] is applied to obtain

$$\mathbf{v}_i(t+\Delta t) = \mathbf{v}_i(t) + \frac{1}{2}[\mathbf{a}_i(t) + \mathbf{a}_i(t+\Delta t)]\Delta t$$

The position of the particles is expanded in a Taylor series.

$$\mathbf{r}_i(t+\Delta t) = \mathbf{r}_i(t) + \mathbf{v}_i\Delta t + \frac{1}{2}\mathbf{a}_i(t)\Delta t^2$$

Beginning with values of $\{\mathbf{r}\}$ and $\{\mathbf{v}\}$ at time 0, one calculates the new positions and then the new velocities. This method is second-order in Δt, too. For additional details, see Allen, M. P., and D. J. Tildesley, *Computer Simulation of Liquids*, Clarendon Press, Oxford (1989); Frenkel, D., and B. Smit, *Understanding Molecular Simulation*, Academic Press (2002); Haile, J. M., *Molecular Dynamics Simulation*, Wiley (1992); Leach, A. R., *Molecular Modelling: Principles and Applications*, Prentice-Hall (2001); Schlick, T., *Molecular Modeling and Simulations*, Springer, New York (2002).

ORDINARY DIFFERENTIAL EQUATIONS-BOUNDARY VALUE PROBLEMS

Diffusion problems in one dimension lead to boundary value problems. The boundary conditions are applied at two different spatial

locations: at one side the concentration may be fixed and at the other side the flux may be fixed. Because the conditions are specified at two different locations, the problems are not initial value in character. It is not possible to begin at one position and integrate directly because at least one of the conditions is specified somewhere else and there are not enough conditions to begin the calculation. Thus, methods have been developed especially for boundary value problems.

Boundary value methods provide a description of the solution either by providing values at specific locations or by an expansion in a series of functions. Thus, the key issues are the method of representing the solution, the number of points or terms in the series, and how the approximation converges to the exact answer, i.e., how the error changes with the number of points or number of terms in the series. These issues are discussed for each of the methods: finite difference, orthogonal collocation, and Galerkin finite element methods.

Finite Difference Method To apply the finite difference method, we first spread grid points through the domain. Figure 3-48 shows a uniform mesh of n points (nonuniform meshes are possible, too). The unknown, here $c(x)$, at a grid point x_i is assigned the symbol $c_i = c(x_i)$. The finite difference method can be derived easily by using a Taylor expansion of the solution about this point. Expressions for the derivatives are:

$$\left.\frac{dc}{dx}\right|_i = \frac{c_{i+1} - c_i}{\Delta x} - \left.\frac{d^2c}{dx^2}\right|_i \frac{\Delta x}{2} + \cdots, \quad \left.\frac{dc}{dx}\right|_i = \frac{c_i - c_{i-1}}{\Delta x} + \left.\frac{d^2c}{dx^2}\right|_i \frac{\Delta x}{2} + \cdots$$

$$\left.\frac{dc}{dx}\right|_i = \frac{c_{i+1} - c_{i-1}}{2\Delta x} - \left.\frac{d^3c}{dx^3}\right|_i \frac{\Delta x^2}{3!} + \cdots$$

The truncation error in the first two expressions is proportional to Δx, and the methods are said to be first-order. The truncation error in the third expression is proportional to Δx^2, and the method is said to be second-order. Usually the last equation is used to insure the best accuracy. The finite difference representation of the second derivative is:

$$\left.\frac{d^2c}{dx^2}\right|_i = \frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2} - \left.\frac{d^4c}{dx^4}\right|_i \frac{2\Delta x^2}{4!} + \cdots$$

The truncation error is proportional to Δx^2. To solve a differential equation, it is evaluated at a point i and then these expressions are inserted for the derivatives.

Example Consider the equation for convection, diffusion, and reaction in a tubular reactor.

$$\frac{1}{\mathrm{Pe}}\frac{d^2c}{dx^2} - \frac{dc}{dx} = \mathrm{Da}\, R(c)$$

The finite difference representation is

$$\frac{1}{\mathrm{Pe}}\frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2} - \frac{c_{i+1} - c_{i-1}}{2\Delta x} = \mathrm{Da}\, R(c_i)$$

This equation is written for $i = 2$ to $n - 1$, or the internal points. The equations would then be coupled but would also involve the values of c_1 and c_n, as well. These are determined from the boundary conditions.

If the boundary condition involves a derivative, it is important that the derivatives be evaluated using points that exist. Three possibilities exist:

$$\left.\frac{dc}{dx}\right|_1 = \frac{c_2 - c_1}{\Delta x}$$

$$\left.\frac{dc}{dx}\right|_1 = \frac{-3c_1 + 4c_2 - c_3}{2\Delta x}$$

The third alternative is to add a false point, outside the domain, as $c_0 = c(x = -\Delta x)$.

$$\left.\frac{dc}{dx}\right|_1 = \frac{c_2 - c_0}{2\Delta x}$$

Since this equation introduces a new variable, c_0, another equation is needed and is obtained by writing the finite difference equation for $i = 1$, too.

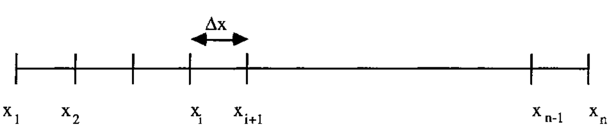

FIG. 3-48 Finite difference mesh; Δx uniform.

The sets of equations can be solved using the Newton-Raphson method. The first form of the derivative gives a tridiagonal system of equations, and the standard routines for solving tridiagonal equations suffice. For the other two options, some manipulation is necessary to put them into a tridiagonal form.

Frequently, the transport coefficients, such as diffusion coefficient or thermal conductivity, depend on the dependent variable, concentration, or temperature, respectively. Then the differential equation might look like

$$\frac{d}{dx}\left(D(c)\,\frac{dc}{dx}\right) = 0$$

This could be written as two equations.

$$-\frac{dJ}{dx} = 0 \qquad J = -D(c)\,\frac{dc}{dx}$$

Because the coefficient depends on c, the equations are more complicated. A finite difference method can be written in terms of the fluxes at the midpoints, $i + 1/2$.

$$-\frac{J_{i+1/2} - J_{i-1/2}}{\Delta x} = 0 \qquad J_{i+1/2} = -D(c_{i+1/2})\,\frac{c_{i+1} - c_i}{\Delta x}$$

These are combined to give the complete equation.

$$\frac{D(c_{i+1/2})\,(c_{i+1} - c_i) - D(c_{i-1/2})\,(c_i - c_{i-1})}{\Delta x^2} = 0$$

This represents a set of nonlinear algebraic equations that can be solved with the Newton-Raphson method. However, in this case, a viable iterative strategy is to evaluate the transport coefficients at the last value and then solve

$$\frac{D(c^k_{i+1/2})\,(c^{k+1}_{i+1} - c^{k+1}_i) - D(c^k_{i-1/2})\,(c^{k+1}_i - c^{k+1}_{i-1})}{\Delta x^2} = 0$$

The advantage of this approach is that it is easier to program than a full Newton-Raphson method. If the transport coefficients do not vary radically, then the method converges. If the method does not converge, then it may be necessary to use the full Newton-Raphson method.

There are two common ways to evaluate the transport coefficient at the midpoint: Use the average value of the solution on each side to evaluate the diffusivity, or use the average value of the diffusivity on each side. Both methods have truncation error Δx^2 (Finlayson, 2003). The spacing of the grid points need not be uniform; see Finlayson (2003) and Finlayson et al. (2006) for the formulas in that case.

Example A reaction diffusion problem is solved with the finite difference method.

$$\frac{d^2c}{dx^2} = \phi^2 c, \quad \frac{dc}{dx}(0) = 0, \quad c(1) = 1$$

The solution is derived for $\phi = 2$. It is solved several times, first with two intervals and three points (at $x = 0, 0.5, 1$), then with four intervals, then with eight intervals. The reason is that when an exact solution is not known, one must use several Δx and see that the solution converges as Δx approaches zero. With two intervals, the equations are as follows. The points are $x_1 = 0$, $x_2 = 0.5$, and $x_3 = 1.0$; and the solution at those points are c_1, c_2, and c_3, respectively. A false boundary is used at $x_0 = -0.5$.

$$\frac{c_0 - c_2}{2\Delta x} = 0, \quad \frac{c_0 - 2c_1 + c_2}{\Delta x^2} - \phi^2 c_1 = 0, \quad \frac{c_1 - 2c_2 + c_3}{\Delta x^2} - \phi^2 c_2 = 0, \quad c_3 = 1$$

The solution is $c_1 = 0.2857$, $c_2 = 0.4286$, and $c_3 = 1.0$. The problem is solved again with four and then eight intervals. The value of concentration at $x = 0$ takes the following values for different Δx. These values are extrapolated using the Richardson extrapolation technique to give $c(0) = 0.265718$. Using this value as the best estimate of the exact solution, the errors in the solution are tabulated versus Δx. Clearly the errors go as Δx^2 (decreasing by a factor of 4 when Δx decreases by a factor of 2), thus validating the solution. The exact solution is 0.265802.

$n - 1$	Δx	$c(0)$
2	0.5	0.285714
4	0.25	0.271043
8	0.125	0.267131

$n - 1$	Δx	Error in $c(0)$
2	0.5	0.02000
4	0.25	0.00532
8	0.125	0.00141

Finite Difference Methods Solved with Spreadsheets A convenient way to solve the finite difference equations for simple problems is to use a computer spreadsheet. The equations for the problem solved in the example can be cast into the following form

$$c_1 = \frac{2c_2}{2 + \phi^2 \Delta x^2}$$

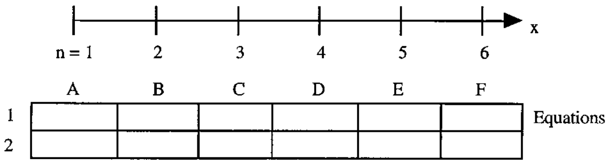

FIG. 3-49 Finite difference method using spreadsheets.

$$c_i = \frac{c_{i+1} + c_{i-1}}{2 + \phi^2 \Delta x^2}$$

$$c_{n+1} = 1$$

Let us solve the problem using 6 nodes, or 5 intervals. Then the connection between the cell in the spreadsheet and the nodal value is shown in Fig. 3-49. The following equations are placed into the various cells.

```
A1: = 2*B1/(2.+(phi*dx)**2)
B1: = (A1 + C1)/(2.+(phi*dx)**2)
F1: = 1.
```

The equation in cell B1 is copied into cells C1 though E1. Then turn on the iteration scheme in the spreadsheet and watch the solution converge. Whether or not convergence is achieved can depend on how you write the equations, so some experimentation may be necessary. Theorems for convergence of the successive substitution method are useful in this regard.

Orthogonal Collocation The orthogonal collocation method has found widespread application in chemical engineering, particularly for chemical reaction engineering. In the collocation method, the dependent variable is expanded in a series of orthogonal polynomials. See "Interpolation and Finite Differences: Lagrange Interpolation Formulas."

$$c(x) = \sum_{m=0}^{N} a_m P_m(x)$$

The differential equation is evaluated at certain collocation points. The collocation points are the roots to an orthogonal polynomial, as first used by Lanczos [Lanczos, C., *J. Math. Phys.* **17:**123–199 (1938); and Lanczos, C., *Applied Analysis*, Prentice-Hall (1956)]. A major improvement was proposed by Villadsen and Stewart [Villadsen, J. V., and W. E. Stewart, *Chem. Eng. Sci.* **22:**1483–1501 (1967)], who proposed that the entire solution process be done in terms of the solution at the collocation points rather than the coefficients in the expansion. This method is especially useful for reaction-diffusion problems that frequently arise when modeling chemical reactors. It is highly efficient when the solution is smooth, but the finite difference method is preferred when the solution changes steeply in some region of space. The error decreases very rapidly as N is increased since it is proportional to $[1/(1-N)]^{N-1}$. See Finlayson (2003) and Villadsen, J. V., and M. Michelsen, *Solution of Differential Equation Models by Polynomial Approximations*, Prentice-Hall (1978).

Galerkin Finite Element Method In the finite element method, the domain is divided into elements and an expansion is made for the solution on each finite element. In the Galerkin finite element method an additional idea is introduced: the Galerkin method is used to solve the equation. The Galerkin method is explained before the finite element basis set is introduced, using the equations for reaction and diffusion in a porous catalyst pellet.

$$\frac{d^2c}{dx^2} = \phi^2 R(c)$$

$$\frac{dc}{dx}(0) = 0, \quad c(1) = 1$$

The unknown solution is expanded in a series of known functions $\{b_i(x)\}$ with unknown coefficients $\{a_i\}$.

$$c(x) = \sum_{i=1}^{NT} a_i b_i(x)$$

The trial solution is substituted into the differential equation to obtain the residual.

$$\text{Residual} = \sum_{i=1}^{NT} a_i \frac{d^2 b_i}{dx^2} - \phi^2 R\left[\sum_{i=1}^{NT} a_i b_i(x)\right]$$

The residual is then made orthogonal to the set of basis functions.

$$\int_0^1 b_j(x) \left\{\sum_{i=1}^{NT} a_i \frac{d^2 b_i}{dx^2} - \phi^2 R\left[\sum_{i=1}^{NT} a_i b_i(x)\right]\right\} dx = 0 \qquad j = 1, \ldots, NT$$

This is the process that makes the method a Galerkin method. The basis for the orthogonality condition is that a function that is made orthogonal to each member of a complete set is then zero. The residual is being made orthogonal, and if the basis functions are complete and you use infinitely many of them, then the residual is zero. Once the residual is zero, the problem is solved.

This equation is integrated by parts to give the following equation

$$-\sum_{i=1}^{NT} \int_0^1 \frac{db_j}{dx}\frac{db_i}{dx}\, dx a_i = \phi^2 \int_0^1 b_j(x) R\left[\sum_{i=1}^{NT} a_i b_i(x)\right] dx$$

$$j = 1, \ldots, NT - 1 \qquad (3\text{-}80)$$

This equation defines the Galerkin method and a solution that satisfies this equation (for all $j = 1, \ldots, \infty$) is called a weak solution. For an approximate solution, the equation is written once for each member of the trial function, $j = 1, \ldots, NT - 1$, and the boundary condition is applied.

$$\sum_{i=1}^{NT} a_i b_i(1) = c_B$$

The Galerkin finite element method results when the Galerkin method is combined with a finite element trial function. The domain is divided into elements separated by nodes, as in the finite difference method. The solution is approximated by a linear (or sometimes quadratic) function of position within the element. These approximations are substituted into Eq. (3-80) to provide the Galerkin finite element equations. For example, with the grid shown in Fig. 3-48, a linear interpolation would be used between points x_i and x_{i+1}.

$$c(x) = c_i(1-u) + c_{i+1}u \quad u \equiv \frac{x - x_i}{x_{i+1} - x_i}$$

A finite element method based on these functions would have an error proportional to Δx^2. The finite element representations for the first derivative and second derivative are the same as in the finite difference method, but this is not true for other functions or derivatives. With quadratic finite elements, take the region from x_{i-1} and x_{i+1} as one element. Then the interpolation would be

$$c(x) = c_{i-1}N_1(u) + c_i N_2(u) + c_{i+1}N_3(u)$$

$$N_1(u) = 2(u-1)\left(u - \frac{1}{2}\right) \quad N_2(u) = 4u(1-u)$$

$$N_3(u) = 2u\left(u - \frac{1}{2}\right)$$

A finite element method based on these functions would have an error proportional to Δx^3. Thus, it would converge faster than one based on linear interpolation. A variety of other finite element functions can be used as well, including B splines (see "Interpolation and Finite Differences: Spline Functions").

Adaptive Meshes In many two-point boundary value problems, the difficulty in the problem is the formation of a boundary layer region, or a region in which the solution changes very dramatically. In such cases, it is prudent to use small mesh spacing there, either with the finite difference method or the finite element method. If the region is known *a priori,* small mesh spacings can be assumed at the boundary layer. If the region is not known, though, other techniques must be used. These techniques are known as adaptive mesh techniques. The mesh size is made small where some property of the solution is large. For example, if the truncation error of the method is nth order, then the nth-order derivative of the solution is evaluated and a small mesh is used where it is large. Alternatively, the residual (the differential equation with the numerical

solution substituted into it) can be used as a criterion. It is also possible to define the error that is expected from a method one order higher and one order lower. Then a decision about whether to increase or decrease the order of the method can be made, taking into account the relative work of the different orders. This provides a method of adjusting both the mesh spacing (Δx, or sometimes called h) and the degree of polynomial (p). Such methods are called *h-p* methods. Many finite element programs have the capability to do this mesh refinement automatically.

Singular Problems and Infinite Domains If the solution being sought has a singularity, it may be difficult to find a good numerical solution. Sometimes even the location of the singularity may not be known. One method of solving such problems is to refine the mesh near the singularity, relying on the better approximation due to a smaller Δx. Another approach is to incorporate the singular trial function into the approximation. Thus, if the solution approaches $f(x)$ as x goes to zero and $f(x)$ becomes infinite, one may define a new variable $u(x) = y(x) - f(x)$ and derive an equation for u. The differential equation is more complicated, but the solution is better near the singularity. Press et al. (1986).

Sometimes the domain is semi-infinite, as in boundary layer flow. The domain can be transformed from the x domain $(0 - \infty)$ to the η domain $(1 - 0)$ using the transformation $\eta = \exp(-x)$. Another approach is to use a variable mesh, perhaps with the same transformation. For example, use $\eta = \exp(-\beta x)$ and a constant mesh size in η; the value of β is found experimentally. Still another approach is to solve on a finite mesh in which the last point is far enough away that its location does not influence the solution. A location that is far enough away must be found by trial and error.

Packages to solve boundary value problems are available on the Internet. On the NIST web page http://gams.nist.gov/, choose "problem decision tree" and then "differential and integral equations" and then "ordinary differential equations" and "multipoint boundary value problems." On the Netlib web site http://www.netlib.org/, search on "boundary value problem." Any spreadsheet that has an iteration capability can be used with the finite difference method. Some packages for partial differential equations also have a capability for solving one-dimensional boundary value problems [e.g. Comsol Multiphysics (formerly FEMLAB)].

NUMERICAL SOLUTION OF INTEGRAL EQUATIONS

In this subsection is considered a method of solving numerically the Fredholm integral equation of the second kind:

$$u(x) = f(x) + \lambda \int_a^b k(x, t)u(t)\,dt \qquad \text{for } u(x) \tag{3-81}$$

The method discussed arises because a definite integral can be closely approximated by any of several numerical integration formulas (each of which arises by approximating the function by some polynomial over an interval). Thus the definite integral in Eq. (3-81) can be replaced by an integration formula, and Eq. (3-81) may be written

$$u(x) = f(x) + \lambda(b - a)\left[\sum_{i=1}^{n} c_i k(x, t_i)u(t_i)\right] \tag{3-82}$$

where $t_1, \ldots, t_n$ are points of subdivision of the t axis, $a \le t \le b$, and the c's are coefficients whose values depend upon the type of numerical integration formula used. Now Eq. (3-82) must hold for all values of x, $a \le x \le b$; so it must hold for $x = t_1, x = t_2, \ldots, x = t_n$. Substituting for x successively $t_1, t_2, \ldots, t_n$ and setting $u(t_i) = u_i$, $f(t_i) = f_i$, we get n linear algebraic equations for the n unknowns $u_1, \ldots, u_n$. That is,

$$u_i = f_i + \lambda(b - a)[c_1 k(t_i, t_1)u_1 + c_2 k(t_i, t_2)u_2 + \cdots + c_n k(t_i, t_n)u_n] \qquad i = 1, 2, \ldots, n$$

These u_j may be solved for by the methods under "Numerical Solution of Linear Equations and Associated Problems" and substituted into Eq. (3-82) to yield an approximate solution for Eq. (3-81).

Because of the work involved in solving large systems of simultaneous linear equations it is desirable that only a small number of u's be computed. Thus the gaussian integration formulas are useful because of the economy they offer.

Solutions for Volterra equations are done in a similar fashion, except that the solution can proceed point by point, or in small groups of points depending on the quadrature scheme. See Linz, P., *Analytical and Numerical Methods for Volterra Equations,* SIAM, Philadelphia (1985). There are methods that are analogous to the usual methods for integrating differential equations (Runge-Kutta, predictor-corrector, Adams methods, etc.). Explicit methods are fast and efficient until the time step is very small to meet the stability requirements. Then implicit methods are used, even though sets of simultaneous algebraic equations must be solved. The major part of the calculation is the evaluation of integrals, however, so that the added time to solve the algebraic equations is not excessive. Thus, implicit methods tend to be preferred. Volterra equations of the first kind are not well posed, and small errors in the solution can have disastrous consequences. The boundary element method uses Green's functions and integral equations to solve differential equations. See Brebbia, C. A., and J. Dominguez, *Boundary Elements—An Introductory Course,* 2d ed., Computational Mechanics Publications, Southhampton (1992); and Mackerle, J., and C. A. Brebbia (eds.), *Boundary Element Reference Book,* Springer-Verlag (1988).

MONTE CARLO SIMULATIONS

Some physical problems, such as those involving interaction of molecules, are usually formulated as integral equations. Monte Carlo methods are especially well-suited to their solution. This section cannot give a comprehensive treatment of such methods, but their use in calculating the value of an integral will be illustrated. Suppose we wish to calculate the integral

$$G = \int_{\Omega_0} g(x)f(x)\,dx$$

where the distribution function $f(x)$ satisfies:

$$f(x) \ge 0, \qquad \int_{\Omega_0} f(x)\,dx = 1$$

The distribution function $f(x)$ can be taken as constant; for example, $1/\Omega_0$. We choose variables $x_1, x_2, \ldots, x_N$ randomly from $f(x)$ and form the arithmetic mean

$$G_N = \frac{1}{N}\sum_i g(x_i)$$

The quantity G_N is an estimation of G, and the fundamental theorem of Monte Carlo guarantees that the expected value of G_N is G, if G exists [Kalos, M. H., and P. A. Whitlock, *Monte Carlo Methods,* vol. 1, Wiley, New York (1986)]. The error in the calculation is given by

$$\varepsilon = \frac{\sigma_1}{N^{1/2}}$$

where σ_1^2 is calculated from

$$\sigma_1^2 = \int_{\Omega_0} g^2(x)\,f(x)\,dx - G^2$$

Thus the number of terms needed to achieve a specified accuracy ϵ can be calculated once an estimate of σ_1^2 is known.

$$N = \frac{\sigma_1^2}{\varepsilon}$$

Various methods, such as influence sampling, can be used to reduce the number of calculations needed. See also Lapeyre, B., *Introduction to Monte-Carlo Methods for Transport and Diffusion Equations*, Oxford University Press (2003), and Liu, J. S., *Monte Carlo Strategies in Scientific Computing*, Springer (2001). Some computer programs are available that perform simple Monte Carlo calculations using Microsoft Excel.

NUMERICAL SOLUTION OF PARTIAL DIFFERENTIAL EQUATIONS

The numerical methods for partial differential equations can be classified according to the type of equation (see "Partial Differential Equations"): parabolic, elliptic, and hyperbolic. This section uses the finite difference method to illustrate the ideas, and these results can be programmed for simple problems. For more complicated problems, though, it is common to rely on computer packages. Thus, some discussion is given to the issues that arise when using computer packages.

Parabolic Equations in One Dimension By combining the techniques applied to initial value problems and boundary value problems it

is possible to easily solve parabolic equations in one dimension. The method is often called the method of lines. It is illustrated here using the finite difference method, but the Galerkin finite element method and the orthogonal collocation method can also be combined with initial value methods in similar ways. The analysis is done by example. The finite volume method is described under Hyperbolic Equations.

Example Consider the diffusion equation, with boundary and initial conditions.

$$\frac{\partial c}{\partial t} = D\,\frac{\partial^2 c}{\partial x^2}$$

$$c(x, 0) = 0$$

$$c(0, t) = 1, \quad c(1, t) = 0$$

We denote by c_i the value of $c(x_i, t)$ at any time. Thus, c_i is a function of time, and differential equations in c_i are ordinary differential equations. By evaluating the diffusion equation at the ith node and replacing the derivative with a finite difference equation, the following working equation is derived for each node i, $i = 2, \ldots, n$ (see Fig. 3-50).

$$\frac{dc_i}{dt} = D\,\frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2}$$

This can be written in the general form of a set of ordinary differential equations by defining the matrix **AA.**

$$\frac{d\mathbf{c}}{dt} = \mathbf{AAc}$$

This set of ordinary differential equations can be solved using any of the standard methods, and the stability of the integration of these equations is governed by the largest eigenvalue of **AA.** When Euler's method is used to integrate in time, the equations become

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = D\,\frac{c_{i+1}^n - 2c_i^n + c_{i-1}^n}{\Delta x^2}$$

where $c_i^n = c(x_i, t^n)$. Notice that if the solution is known at every point at one time n, then it is a straightforward calculation to find the solution at every point at the new time $n+1$.

If Euler's method is used for integration, the time step is limited by

$$\Delta t \le \frac{2}{|\lambda|_{\max}}$$

whereas if the Runge-Kutta-Feldberg method is used, the 2 in the numerator is replaced by 3.0. The largest eigenvalue of **AA** is bounded by Gerschgorin's Theorem.

$$|\lambda|_{\max} \le \max_{2<j<n} \sum_{i=2}^{n} |\mathbf{AA}_{ji}| = \frac{4D}{\Delta x^2}$$

This gives the well-known stability limit

$$\Delta t\,\frac{D}{\Delta x^2} \le \frac{1}{2}$$

The smallest eigenvalue is independent of Δx (it is $D\pi^2/L^2$) so that the ratio of largest to smallest eigenvalue is proportional to $1/\Delta x^2$. Thus, the problem becomes stiff as Δx approaches zero. See Eq. (3-79).

The effect of the increased stiffness is that a smaller and smaller time step (Δt) must be taken as the mesh is refined ($\Delta x^2 \to 0$). At the same time, the number of points is increasing, so that the computation becomes very lengthy. Implicit methods are used to overcome this problem.

Write a finite difference form for the time derivative and average the right-hand sides, evaluated at the old and new time.

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = D(1-\theta)\,\frac{c_{i+1}^n - 2c_i^n + c_{i-1}^n}{\Delta x^2} + D\theta\,\frac{c_{i+1}^{n+1} - 2c_i^{n+1} + c_{i-1}^{n+1}}{\Delta x^2}$$

Now the equations are of the form

$$-\frac{D\Delta t\theta}{\Delta x^2}\,c_{i+1}^{n+1} + \left[1 + 2\,\frac{D\Delta t\theta}{\Delta x^2}\right] c_i^{n+1} - \frac{D\Delta t\theta}{\Delta x^2}\,c_{i-1}^{n+1}$$

$$= c_i^n + \frac{D\Delta t(1-\theta)}{\Delta x^2}\,(c_{i+1}^n - 2c_i^n + c_{i-1}^n)$$

and require solving a set of simultaneous equations, which have a tridiagonal structure. Using $\theta = 0$ gives the Euler method (as above),

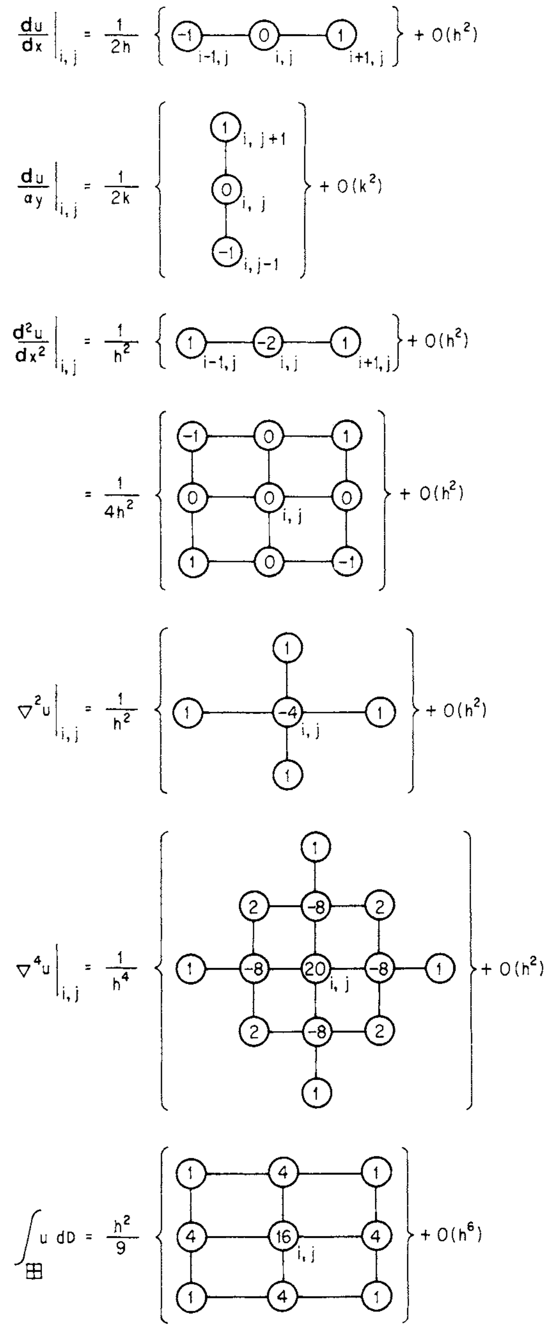

FIG. 3-50 Computational molecules. $h = \Delta x = \Delta y$.

$\theta = 0.5$ gives the Crank-Nicolson method, and $\theta = 1$ gives the backward Euler method. The Crank-Nicolson method is also the same as applying the trapezoid rule to do the integration. The stability limit is given by

$$\frac{D\Delta t}{\Delta x^2} \le \frac{0.5}{1 - 2\theta}$$

The price of using implicit methods is that one now has a system of equations to solve at each time step, and the solution methods are more complicated (particularly for nonlinear problems) than the straightforward explicit methods. Phenomena that happen quickly can also be obliterated or smoothed over by using a large time step, so implicit methods are not suitable in all cases. The engineer must decide if he or she wants to track those fast phenomena, and choose an appropriate method that handles the time scales that are important in the problem.

Other methods can be used in space, such as the finite element method, the orthogonal collocation method, or the method of orthogonal collocation on finite elements. One simply combines the methods for ordinary differential equations (see "Ordinary Differential Equations—Boundary Value Problems") with the methods for initial-value problems (see "Numerical Solution of Ordinary Differential Equations as Initial Value Problems"). Fast Fourier transforms can also be used on regular grids (see "Fast Fourier Transform").

Elliptic Equations Elliptic equations can be solved with both finite difference and finite element methods. One-dimensional elliptic problems are two-point boundary value problems. Two- and three-dimensional elliptic problems are often solved with iterative methods when the finite difference method is used and direct methods when the finite element method is used. So there are two aspects to consider: how the equations are discretized to form sets of algebraic equations and how the algebraic equations are then solved.

The prototype elliptic problem is steady-state heat conduction or diffusion,

$$k\left(\frac{\partial^2 T}{\partial x^2}+\frac{\partial^2 T}{\partial y^2}\right)=Q$$

possibly with a heat generation term per unit volume, Q. The boundary conditions taken here are $T = f(x, y)$ on the boundary (S) with f a known function. Illustrations are given for constant thermal conductivity k while Q is a known function of position. The finite difference formulation is given using the following nomenclature:

$$T_{i,j} = T(i\Delta x, j\Delta y)$$

The finite difference formulation is then (see Fig. 3-50)

$$\frac{T_{i+1,j}-2T_{i,j}+T_{i-1,j}}{\Delta x^2}+\frac{T_{i,j+1}-2T_{i,j}+T_{i,j-1}}{\Delta y^2}=Q_{i,j} \qquad (3\text{-}83)$$

$$T_{i,j} = f(x_i, y_j) \text{ on } S$$

If the boundary is parallel to a coordinate axis any derivative is evaluated as in the section on boundary value problems, using either a one-sided, centered difference or a false boundary. If the boundary is more irregular and not parallel to a coordinate line then more complicated expressions are needed and the finite element method may be the better method.

Equation (3-83) provides a set of linear equations that must be solved. These equations and their boundary conditions may be written in matrix form as

$$\mathbf{At} = \mathbf{f}$$

where $\mathbf{t}$ is the set of temperatures at all the points, $\mathbf{f}$ is the set of heat generation terms at all points, and $\mathbf{A}$ is formed from the coefficients of T_{ij} in Eq. (3-83). The solution can be obtained simply by solving the set of linear equations. For three-dimensional problems, the matrix $\mathbf{A}$ is sparse, and iterative methods are used. These include Gauss-Seidel, alternating direction, overrelaxation methods, conjugate gradient, and multigrid methods. In Gauss-Seidel methods, one writes the equation for T_{ij} in terms of the other temperatures and cycles through all the points over and over. In the alternating direction method, one solves along one line (that is, x = constant), keeping the side values fixed, and then repeats this for all lines, and then repeats the process. Multigrid methods solve the problem on successively refined grids, which has advantages for both convergence and error estimation. Conjugate gradient methods frequently use a preconditioned matrix. The equation is multiplied by another matrix, which is chosen so that the resulting problem is easier to solve than the original one. Finding such matrices is an art, but it can speed convergence. The generalized minimal residual method is described in http://mathworld.wolfram.com/GeneralizedMinimalResidualMethod.html. Additional resources can be found at http://www.netlib.org/linalg/html_templates/Templates.html. When the problem is nonlinear, the iterative methods may not converge, or the mesh may have to be refined before they converge, so some experimentation is sometimes necessary.

Spreadsheets can be used to solve two-dimensional problems on rectangular grids. The equation for T_{ij} is obtained by rearranging Eq. (3-83).

$$2\left(1+\frac{\Delta x^2}{\Delta y^2}\right)T_{i,j} = T_{i+1,j} + T_{i-1,j} + \frac{\Delta x^2}{\Delta y^2}(T_{i,j+1} + T_{1,j-1}) - \Delta x^2\,\frac{Q_{i,j}}{k}$$

This equation is inserted into a cell and copied throughout the space represented by all the cells; when the iteration feature is turned on, the solution is obtained.

The Galerkin finite element method (FEM) is useful for solving elliptic problems and is particularly effective when the domain or geometry is irregular. As an example, cover the domain with triangles and define a trial function on each triangle. The trial function takes the value 1.0 at one corner and 0.0 at the other corners and is linear in between. See Fig. 3-51. These trial functions on each triangle are pieced together to give a trial function on the whole domain. General treatments of the finite element method are available (see references). The steps in the solution method are similar to those described for boundary value problems, except now the problems are much bigger so that the numerical analysis must be done very carefully to be efficient. Most engineers, though, just use a finite element program without generating it. There are three major caveats that must be addressed. The first one is that the solution is dependent on the mesh laid down, and the only way to assess the accuracy of the solution is to solve the problem with a more refined mesh. The second concern is that the solution obeys the shape of the trial function inside the element. Thus, if linear functions are used on triangles, a three-dimensional view of the solution, plotting the solution versus x and y, consists of a series of triangular planes joined together at the edges, as in a geodesic dome. The third caveat is that the Galerkin finite element method is applied to both the differential equations and the boundary conditions. Computer programs are usually quite general and may allow the user to specify boundary conditions that are not realistic. Also, natural boundary conditions are satisfied if no other boundary condition (ones involving derivatives) is set at a node. Thus, the user of finite element codes must be very clear what boundary conditions and differential equations are built into the computer code. When the problem is nonlinear, the Newton-Raphson method is used to iterate from an initial guess. Nonlinear problems lead to complicated integrals to evaluate, and they are usually evaluated using Gaussian quadrature.

One nice feature of the finite element method is the use of natural boundary conditions. It may be possible to solve the problem on a domain that is shorter than needed to reach some limiting condition (such as at an outflow boundary). The externally applied flux is still applied at the shorter domain, and the solution *inside* the truncated domain is still valid. Examples are given in Chang, M. W., and B. A. Finlayson, *Int. J. Num. Methods Eng.* **15,** 935–942 (1980), and Finlason, B. A. (1992). The effect of this is to allow solutions in domains that are smaller, thus saving computation time and permitting the solution in semi-infinite domains.

The trial functions in the finite element method are not limited to linear ones. Quadratic functions and even higher-order functions are frequently used. The same considerations hold as for boundary value problems: The higher-order trial functions converge faster, but require more work. It is possible to refine both the mesh h and the power of polynomial in the trial function p in an hp method. Some problems have constraints on some of the variables. For flow problems, the pressure must usually be approximated by using a trial function that is one order lower than the polynomial used to approximate the velocity.

Hyperbolic Equations The most common situation yielding hyperbolic equations involves unsteady phenomena with convection. Two typical equations are the convective diffusive equation

$$\frac{\partial c}{\partial t}+u\,\frac{\partial c}{\partial x}=D\,\frac{\partial^2 c}{\partial x^2}$$

and the chromatography equation.

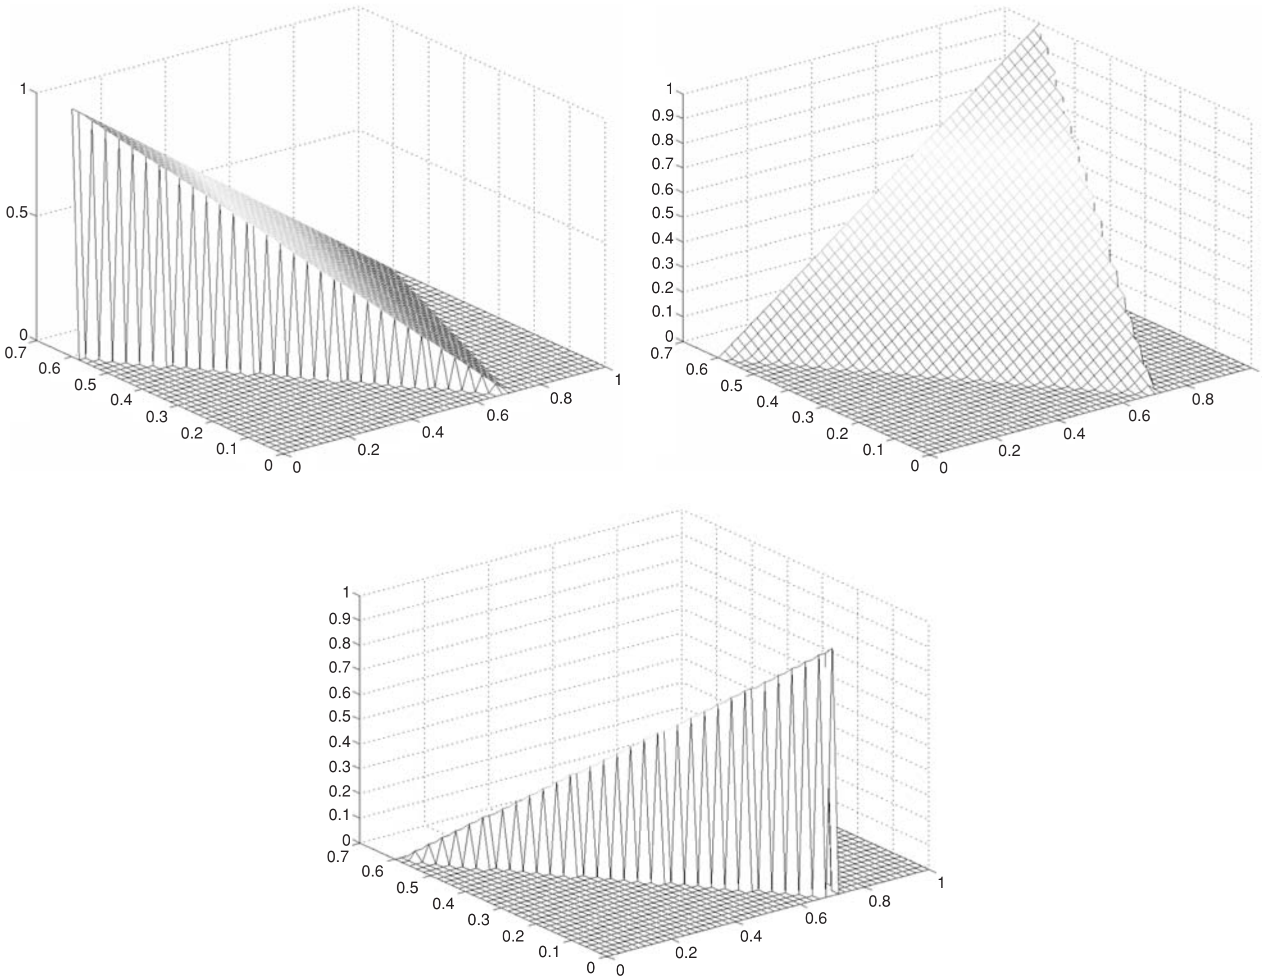

FIG. 3-51 Trial functions for Galerkin finite element method: linear polynomial on triangle.

(See "Partial Differential Equations.") If the diffusion coefficient is zero, the convective diffusion equation is hyperbolic. If D is small, the phenomenon may be essentially hyperbolic, even though the equations are parabolic. Thus the numerical methods for hyperbolic equations may be useful even for parabolic equations.

Equations for several methods are given here, as taken from the book by Finlayson [Finlayson, B. A. (1992)]. If the convective term is treated with a centered difference expression, the solution exhibits oscillations from node to node, and these only go away if a very fine grid is used. The simplest way to avoid the oscillations with a hyperbolic equation is to use upstream derivatives. If the flow is from left to right, this would give

$$\frac{dc_i}{dt} + u\,\frac{c_i - c_{i-1}}{\Delta x} = D\,\frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2}$$

The effect of using upstream derivatives is to add artificial or numerical diffusion to the model. This can be ascertained by rearranging the finite difference form of the convective diffusion equation

$$\frac{dc_i}{dt} + u\,\frac{c_{i+1} - c_{i-1}}{2\Delta x} = \left(D + \frac{u\Delta x}{2}\right)\frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2}$$

Thus the diffusion coefficient has been changed from

$$D \text{ to } D + \frac{u\Delta x}{2}$$

Alternatively, the diffusion coefficient has been multiplied by the factor

$$D' = D\left(1 + \frac{u\Delta x}{2D}\right) = D\left(1 + \frac{\text{Pe}_{\text{cell}}}{2}\right)$$

where $\text{Pe}_{\text{cell}} = \dfrac{u\,\Delta x}{D} = \dfrac{uL}{D}\,\dfrac{\Delta x}{L} = \text{Pe}\,\dfrac{\Delta x}{L}$ is called the cell Peclet number. When the diffusion coefficient is very small (or diffusion is slow compared with convection), the Peclet number will be large. In that case, extraneous diffusion will be included in the solution unless the mesh size (denoted by Δx) is small compared with the characteristic length of the problem. To avoid this problem (by keeping the factor small), very fine meshes must be used, and the smaller the diffusion coefficient, the smaller the required mesh size.

A variety of other methods are used to obtain a good solution without using extremely fine meshes. The flux correction methods keep track of the flux of material into and out of a cell (from one node to another) and put limits on the flux to make sure that no more material

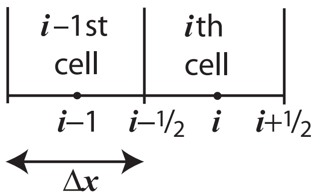

FIG. 3-52 Nomenclature for finite volume method.

leaves the cell than is there originally plus the input amount. See Finlayson, ibid., for many examples.

All the methods have a limit to the time step that is set by the convection term. Essentially, the time step should not be so big as to take the material farther than it can go at its velocity. This is usually expressed as a Courant number limitation.

$$\mathrm{Co} = \frac{u\Delta t}{\Delta x} \leq 1$$

Some methods require a smaller limit, depending upon the amount of diffusion present (see Finlayson, ibid., Appendix).

In the finite element method, Petrov-Galerkin methods are used to minimize the unphysical oscillations. The Petrov-Galerkin method essentially adds a small amount of diffusion in the flow direction to smooth the unphysical oscillations. The amount of diffusion is usually proportional to Δx so that it becomes negligible as the mesh size is reduced. The value of the Petrov-Galerkin method lies in being able to obtain a smooth solution when the mesh size is large, so that the computation is feasible. This is not so crucial in one-dimensional problems, but it is essential in two- and three-dimensional problems and purely hyperbolic problems.

Finite Volume Methods Finite volume methods are utilized extensively in computational fluid dynamics. In this method, a mass balance is made over a cell, accounting for the change in what is in the cell, and the flow in and out. Figure 3-52 illustrates the geometry of the ith cell. A mass balance made on this cell (with area A perpendicular to the paper) is

$$A\,\Delta x\,(c_i^{n+1} - c_i^n) = \Delta t A(J_{j-1/2} - J_{i+1/2})$$

where J is the flux due to convection and diffusion, positive in the $+x$ direction.

$$J = uc - D\frac{\partial c}{\partial x}, \quad J_{i-1/2} = u_{i-1/2}c_{i-1/2} - D\,\frac{c_i - c_{i-1/2}}{\Delta x}$$

The concentration at the edge of the cell is taken as

$$c_{i-1/2} = \frac{1}{2}(c_i + c_{i-1/2})$$

Rearrangement for the case when the velocity u is the same for all nodes gives

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} + \frac{u(c_{i+1} - c_{i-1})}{2\Delta x} = \frac{D}{\Delta x^2}\,(c_{i+1} - 2c_i + c_{i+1})$$

This is the same equation obtained by using the finite difference method. This isn't always true, and the finite volume equations are easy to derive. In two and three dimensions, the mesh need not be rectangular, as long as it is possible to compute the velocity normal to an edge of the cell. The finite volume method is useful for applications involving filling, such as injection molding, when only part of the cell is filled with fluid. Such applications do involve some approximations, since the interface is not tracked precisely, but they are useful engineering approximations.

Parabolic Equations in Two or Three Dimensions Computations become much more lengthy when there are two or more spatial dimensions. For example, we may have the unsteady heat conduction equation

$$\rho C_p \frac{\partial T}{\partial t} = k\left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}\right) - Q$$

Most engineers use computer packages to solve such problems. If there is both convection and diffusion in the problem, the same considerations apply: A fine mesh is needed when the Peclet number is large. The upstream weighting and Petrov-Galerkin methods can be used, but it is important to apply the smoothing only in the direction of flow, since smoothing in the direction transverse to the flow direction would be incorrect. Some transverse smoothing is unavoidable, but the engineer needs to be sure that the smoothing is just enough to allow a good solution without creating large errors.

Computer Software When you are choosing computer software to solve your problem, there are a number of important considerations. The first decision is whether to use an approximate, engineering flow model, developed from correlations, or to solve the partial differential equations that govern the problem. Correlations are quick and easy to apply, but they may not be appropriate to your problem or give the needed detail. When you are using a computer package to solve partial differential equations, the first task is always to generate a mesh covering the problem domain. This is not a trivial task, and special methods have been developed to permit importation of a geometry from a computer-aided design (CAD) program. Then the mesh must be created automatically. If the boundary is irregular, the finite element method is especially well suited, although special embedding techniques can be used in finite difference methods (which are designed to be solved on rectangular meshes). Another capability to consider is the ability to track free surfaces that move during the computation. This phenomenon introduces the same complexity that occurs in problems with a large Peclet number, with the added difficulty that the free surface moves between mesh points and improper representation can lead to unphysical oscillations. The method used to solve the equations is important, and both explicit and implicit methods (as described above) can be used. Implicit methods may introduce unacceptable extra diffusion, so the engineer needs to examine the solution carefully. The methods used to smooth unphysical oscillations from node to node are also important, and the engineer needs to verify that the added diffusion or smoothing does not give inaccurate solutions. Since current-day problems are mostly nonlinear, convergence is always an issue since the problems are solved iteratively. Robust programs provide several methods for convergence, each of which is best in some circumstance or other. It is wise to have a program that includes many iterative methods. If the iterative solver is not very robust, the only recourse to solving a steady-state problem may be to integrate the time-dependent problem to steady state. The solution time may be long, and the final result may be further from convergence than would be the case if a robust iterative solver were used.

A variety of computer programs are available on the Internet, some free. First consider general-purpose programs. On the NIST web page http://gams.nist.gov/, choose "problem decision tree" then "differential and integral equations" and then "partial differential equations." The programs are organized by type of problem (elliptic, parabolic, and hyperbolic) and by the number of spatial dimensions (one or more than one). On the Netlib web site http://www.netlib.org/, search on "partial differential equation." Lau (1994, 2004) provides many programs in C++ (also see http://www.nr.com/). The multiphysics program Comsol Multiphysics (formerly FEMLAB) also solves many standard equations arising in mathematical physics.

Computational fluid dynamics (CFD) programs are more specialized, and most have been designed to solve sets of equations that are appropriate to specific industries. They can then include approximations and correlations for some features that would be difficult to solve for directly. Four major packages widely used are Fluent (http://www.fluent.com/), CFX (now part of ANSYS), Comsol Multiphysics (formerly FEMLAB) (http://www.comsol.com/), and ANSYS (http://www.ansys.com/). Of these, Comsol Multiphysics is particularly useful because it has a convenient graphical-user interface, permits easy mesh generation and refinement (including adaptive mesh refinement), allows the user to add phenomena and equations easily, permits solution by continuation methods (thus enhancing

convergence), and has extensive graphical output capabilities. Other packages are also available (see http://cfd-online.com/), and these may contain features and correlations specific to the engineer's industry. One important point to note is that for turbulent flow, all the programs contain approximations, using the k-epsilon models of turbulence, or large eddy simulations; the direct numerical simulation of turbulence is too slow to apply to very big problems, although it does give insight (independent of any approximations) that is useful for interpreting turbulent phenomena. Thus, the method used to include those turbulent correlations is important, and the method also may affect convergence or accuracy.

FAST FOURIER TRANSFORM

The Fourier transform and inverse transform are

$$Y(\omega) = \int_{-\infty}^{\infty} y(t)e^{i\omega t}\,dt$$

$$y(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} Y(\omega)e\,d\omega$$

Suppose a signal $y(t)$ is sampled at equal intervals

$$y_n = y(n\Delta), \qquad n = \ldots, -2, -1, 0, 1, 2, \ldots$$

$$\Delta = \text{sampling interval (e.g., time between samples)}$$

The Nyquist critical frequency or critical angular frequency is

$$f_c = \frac{1}{2\Delta}, \qquad \omega_c = \frac{\pi}{\Delta}$$

If a function $y(t)$ is bandwidth-limited to frequencies smaller than f_c, such as

$$Y(\omega) = 0 \qquad \text{for } \omega > \omega_c$$

then the function is completely determined by its samples y_n. Thus, the entire information content of a signal can be recorded by sampling at a rate $\Delta^{-1} = 2f_c$. If the function is *not* bandwidth-limited, then aliasing occurs. Once a sample rate Δ is chosen, information corresponding to frequencies greater than f_c is simply aliased into that range. The way to detect this in a Fourier transform is to see if the transform approaches zero at $\pm f_c$; if not, aliasing has occurred, and a higher sampling rate is needed.

Next, suppose we have N samples, where N is even

$$y_k = y(t_k) \qquad t_k = k\Delta \qquad k = 0, 1, 2, \ldots, N-1$$

and the sampling interval is Δ. With only N values $\{y_k\}$, it is not possible to determine the complete Fourier transform $Y(\omega)$. We calculate the value $Y(\omega_n)$ at the discrete points

$$\omega_n = \frac{2\pi n}{N\Delta}, \quad n = -\frac{N}{2}, \ldots, 0, \ldots, \frac{N}{2}$$

$$Y_n = \sum_{k=0}^{N-1} y_k e^{2\pi i k n/N}$$

$$Y(\omega_n) = \Delta Y_n$$

The discrete inverse Fourier transform is

$$y_k = \frac{1}{N}\sum_{n=0}^{N-1} Y_n e^{-2\pi i k n/N}$$

The fast Fourier transform (FFT) is used to calculate the Fourier transform as well as the inverse Fourier transform. A discrete Fourier transform of length N can be written as the sum of two discrete Fourier transforms, each of length $N/2$.

$$Y_k = Y_k^e + W^k Y_k^o$$

Here Y_k is the kth component of the Fourier transform of y, and Y_k^e is the kth component of the Fourier transform of the even components of $\{y_j\}$ and is of length $N/2$. Similarly, Y_k^o is the kth component of the Fourier transform of the odd components of $\{y_j\}$ and is of length $N/2$. W is a constant, which is taken to the kth power.

$$W = e^{2\pi i/N}$$

Since Y_k has N components, while Y_k^e and Y_k^o have $N/2$ components, Y_k^e and Y_k^o are repeated once to give N components in the calculation of Y_k. This decomposition can be used recursively. Thus, Y_k^e is split into even and odd terms of length $N/4$.

$$Y_k^e = Y_k^{ee} + W^k Y_k^{eo}$$

$$Y_k^o = Y_k^{oe} + W^k Y_k^{oo}$$

This process is continued until there is only one component. For this reason, the number N is taken as a power of 2. The vector $\{y_j\}$ is filled with zeroes, if need be, to make $N = 2^p$ for some p. The standard Fourier transform takes N^2 operations to calculate, whereas the fast Fourier transform takes only $N \log_2 N$. For large N, the difference is significant; at $N = 100$ it is a factor of 15, but for $N = 1000$ it is a factor of 100.

The discrete Fourier transform can also be used for differentiating a function, and this is used in the spectral method for solving differential equations [Gottlieb, D., and S. A. Orszag, *Numerical Analysis of Spectral Methods: Theory and Applications,* SIAM, Philadelphia (1977); Trefethen, L. N., *Spectral Methods in Matlab,* SIAM, Philadelphia (2000)]. Suppose we have a grid of equidistant points

$$x_n = n\Delta x, \quad n = 0, 1, 2, \ldots, 2N-1, \qquad \Delta x = \frac{L}{2N}$$

The solution is known at each of these grid points $\{y(x_n)\}$. First the discrete Fourier transform is taken:

$$Y_k = \frac{1}{2N}\sum_{n=0}^{2N-1} y(x_n)e^{-2ik\pi x_n/L}, \; k = -N, -N+1, \ldots, 0, \ldots, N-1, N$$

The inverse transformation is

$$y(x) = \frac{1}{L}\sum_{k=-N}^{N} Y_k e^{2ik\pi x/L}$$

Differentiate this to get

$$\frac{dy}{dx} = \frac{1}{L}\sum_{k=-N}^{N} Y_k \frac{2\pi i k}{L} e^{2ik\pi x/L}$$

Thus at the grid points

$$\left.\frac{dy}{dx}\right|_n = \sum_{k=-N}^{N} Y_k \frac{2\pi i k}{L} e^{2ik\pi x_n/L}$$

The process works as follows. From the solution at all grid points the Fourier transform is obtained using FFT, $\{Y_k\}$. Then this is multiplied by $2\pi i k/L$ to obtain the Fourier transform of the derivative.

$$Y'_k = Y_k \frac{2\pi i k}{L}$$

Then the inverse Fourier transform is taken using FFT, giving the value of the derivative at each of the grid points.

$$\left.\frac{dy}{dx}\right|_n = \frac{1}{L}\sum_{k=-N}^{N} Y'_k e^{2ik\pi x_n/L}$$

The spectral method is used for direct numerical simulation (DNS) of turbulence. The Fourier transform is taken of the differential equation, and the resulting equation is solved. Then the inverse transformation gives the solution. When there are nonlinear terms, they are calculated at each node in physical space, and the Fourier transform is taken of the result. This technique is especially suited to time-dependent problems, and the major computational effort is in the fast Fourier transform.

INTRODUCTION

Optimization is a key enabling tool for decision making in chemical engineering. It has evolved from a methodology of academic interest into a technology that continues to have a significant impact on engineering research and practice. Optimization algorithms form the core tools for (1) experimental design, parameter estimation, model development, and statistical analysis; (2) process synthesis analysis, design, and retrofit; (3) model predictive control and real-time optimization; and (4) planning, scheduling, and the integration of process operations into the supply chain.

As shown in Fig. 3-53, optimization problems that arise in chemical engineering can be classified in terms of continuous and discrete variables. For the former, nonlinear programming (NLP) problems form the most general case, and widely applied specializations include linear programming (LP) and quadratic programming (QP). An important distinction for NLP is whether the optimization problem is convex or nonconvex. The latter NLP problem may have multiple local optima, and an important question is whether a global solution is required for the NLP. Another important distinction is whether the problem is assumed to be differentiable or not.

Mixed integer problems also include discrete variables. These can be written as mixed integer nonlinear programs (MINLP), or as mixed integer linear programs (MILP), if all variables appear linearly in the constraint and objective functions. For the latter an important case occurs when all the variables are integer; this gives rise to an integer programming (IP) problem. IP problems can be further classified into many special problems (e.g., assignment, traveling salesperson, etc.), which are not shown in Fig. 3-53. Similarly, the MINLP problem also gives rise to special problem classes, although here the main distinction is whether its relaxation is convex or nonconvex.

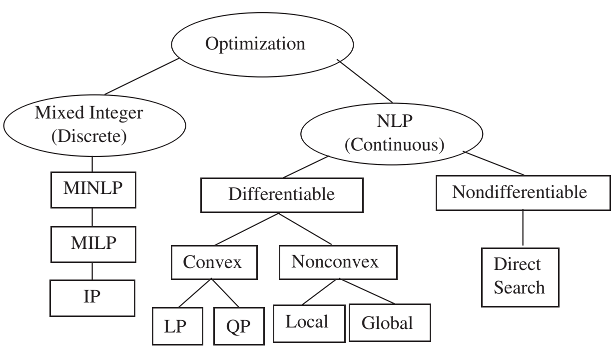

FIG. 3-53 Classes of optimization problems and algorithms.

The ingredients of formulating optimization problems include a mathematical model of the system, an objective function that quantifies a criterion to be extremized, variables that can serve as decisions, and, optionally, inequality constraints on the system. When represented in algebraic form, the general formulation of discrete/continuous optimization problems can be written as the following mixed integer optimization problem:

$$\begin{aligned} &\text{Min } f(x, y) \\ &\text{subject to } h(x, y) = 0 \\ &\qquad g(x, y) \le 0 \\ &\qquad x \in \Re_n,\ y \in \{0, 1\} \end{aligned} \tag{3-84}$$

where $f(x, y)$ is the objective function (e.g., cost, energy consumption, etc.), $h(x, y) = 0$ are the equations that describe the performance of the system (e.g., material balances, production rates), and the inequality constraints $g(x, y) \le 0$ can define process specifications or constraints for feasible plans and schedules. Note that the operator *max* $f(x)$ is equivalent to *min* $[-f(x)]$. We define the real n vector x to represent the continuous variables while the t vector y represents the discrete variables, which, without loss of generality, are often restricted to take values of 0 or 1 to define logical or discrete decisions, such as assignment of equipment and sequencing of tasks. (These variables can also be formulated to take on other integer values as well.) Problem (3-84) corresponds to a mixed integer nonlinear program when any of the functions involved are nonlinear. If all functions are linear, it corresponds to a mixed integer linear program. If there are no 0–1 variables, then problem (3-84) reduces to a nonlinear program (3-85) or linear program (3-97) depending on whether the functions are linear.

We start with continuous variable optimization and consider in the next section the solution of NLP problems with differentiable objective and constraint functions. If only local solutions are required for the NLP problem, then very efficient large-scale methods can be considered. This is followed by methods that are not based on local optimality criteria; we consider direct search optimization methods that do not require derivatives as well as deterministic global optimization methods. Following this, we consider the solution of mixed integer problems and outline the main characteristics of algorithms for their solution. Finally, we conclude with a discussion of optimization modeling software and its implementation on engineering models.

GRADIENT-BASED NONLINEAR PROGRAMMING

For continuous variable optimization we consider (3-84) without discrete variable y. The general NLP problem (3-85) is presented here:

$$\begin{aligned} &\text{Min } f(x) \\ &\text{subject to } h(x) = 0 \\ &\qquad g(x) \le 0 \end{aligned} \tag{3-85}$$

and we assume that the functions $f(x)$, $h(x)$, and $g(x)$ have continuous first and second derivatives. A key characteristic of (3-85) is whether the problem is convex or not, i.e., whether it has a convex objective function and a convex feasible region. A function $\phi(x)$ of x in some domain X is convex if and only if for all points $x_1, x_2 \in X$

$$\phi[\alpha x_1 + (1-\alpha)x_2] \le \alpha\phi[x_1 + (1-\alpha)x_2] + (1-\alpha)\phi(x_2) \tag{3-86}$$

holds for all $\alpha \in (0, 1)$. [Strict convexity requires that the inequality (3-86) be strict.] Convex feasible regions require $g(x)$ to be a convex function and $h(x)$ to be linear. If (3-85) is a convex problem, then any local solution is guaranteed to be a global solution to (3-85). Moreover, if the objective function is strictly convex, then this solution x^* is unique. On the other hand, nonconvex problems may have multiple local solutions, i.e., feasible solutions that minimize the objective function within some neighborhood about the solution.

We consider first methods that find only local solutions to nonconvex problems, as more difficult (and expensive) search procedures are required to find a global solution. Local methods are currently very

efficient and have been developed to deal with very large NLP problems. Moreover, by considering the structure of convex NLP problems (including LP and QP problems), even more powerful methods can be applied. To study these methods, we first consider conditions for local optimality.

Local Optimality Conditions: A Kinematic Interpretation Instead of a formal development of conditions that define a local optimum, we present a more intuitive kinematic illustration. Consider the contour plot of the objective function $f(x)$, given in Fig. 3-54, as a smooth valley in space of the variables x_1 and x_2. For the contour plot of this unconstrained problem Min $f(x)$, consider a ball rolling in this valley to the lowest point of $f(x)$, denoted by x^*. This point is at least a local minimum and is defined by a point with a zero gradient and at least nonnegative curvature in all (nonzero) directions p. We use the first-derivative (*gradient*) vector $\nabla f(x)$ and second-derivative (*Hessian*) matrix $\nabla_{xx} f(x)$ to state the necessary first- and second-order conditions for unconstrained optimality:

$$\nabla_x f(x^*) = 0 \quad p^T \nabla_{xx} f(x^*) p \geq 0 \quad \text{for all } p \neq 0 \qquad (3\text{-}87)$$

These necessary conditions for local optimality can be strengthened to sufficient conditions by making the inequality in (3-87) strict (i.e., positive curvature in all directions). Equivalently, the sufficient (necessary) curvature conditions can be stated as follows: $\nabla_{xx} f(x^*)$ has all positive (nonnegative) eigenvalues and is therefore defined as a positive (semidefinite) definite matrix.

Now consider the imposition of inequality $[g(x) \leq 0]$ and equality constraints $[h(x) = 0]$ in Fig. 3-55. Continuing the kinematic interpretation, the inequality constraints $g(x) \leq 0$ act as "fences" in the valley, and equality constraints $h(x) = 0$ act as "rails." Consider now a ball, constrained on a rail and within fences, to roll to its lowest point. This stationary point occurs when the normal forces exerted by the fences $[-\nabla g(x^*)]$ and rails $[-\nabla h(x^*)]$ on the ball are balanced by the force of gravity $[-\nabla f(x^*)]$. This condition can be stated by the following *Karush-Kuhn-Tucker (KKT) necessary conditions* for constrained optimality:

Balance of Forces It is convenient to define the L function $L(x,\lambda,\nu) = f(x) + g(x)^T\lambda + h(x)^T\nu$, along with "weights" or multipliers λ and ν for the constraints. The stationarity condition (balance of forces acting on the ball) is then given by

$$\nabla L(x, \lambda, \nu) = \nabla f(x) + \nabla h(x)\lambda + \nabla g(x)\nu = 0 \qquad (3\text{-}88)$$

Feasibility Both inequality and equality constraints must be satisfied (ball must lie on the rail and within the fences):

$$h(x) = 0, \quad g(x) \leq 0 \qquad (3\text{-}89)$$

Complementarity Inequality constraints are either strictly satisfied (active) or inactive, in which case they are irrelevant to the solution. In the latter case the corresponding KKT multiplier must be zero. This is written as

$$\nu^T g(x) = 0, \quad \nu \geq 0 \qquad (3\text{-}90)$$

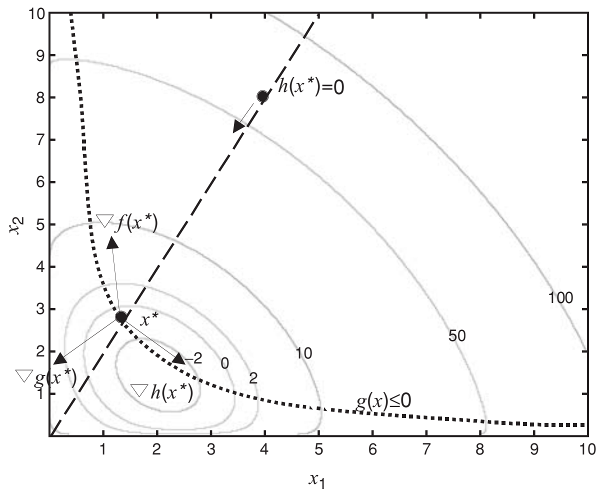

FIG. 3-55 Constrained minimum.

Constraint Qualification For a local optimum to satisfy the KKT conditions, an additional regularity condition is required on the constraints. This can be defined in several ways. A typical condition is that the active constraints at x^* be linearly independent; i.e., the matrix: $[\nabla h(x^*) | \nabla g_A(x^*)]$ is full column rank, where g_A is the vector of inequality constraints with elements that satisfy $g_{A,i}(x^*) = 0$. With this constraint qualification, the KKT multipliers (λ, ν) are guaranteed to be unique at the optimal solution.

Second-Order Conditions As with unconstrained optimization, nonnegative (positive) curvature is necessary (sufficient) in all the allowable (i.e., constrained) nonzero directions p. The necessary second-order conditions can be stated as

$$p^T \nabla_{xx} L(x^*) p \geq 0$$
$$\text{for all } p \neq 0,\ \nabla h(x^*)^T p = 0,\ \nabla g(x^*)^T p \geq 0, \nabla g_A(x^*)^T p = 0 \qquad (3\text{-}91)$$

and the corresponding sufficient conditions require first the inequality in (3-91) to be strict. Note that for the example in Fig. 3-54, the allowable directions p span the entire space for x while in Fig. 3-55 there are *no* allowable directions p.

Example To illustrate the KKT conditions, consider the following unconstrained NLP problem:

$$\text{Min } (x_1)^2 - 4x_1 + 3/2\,(x_2)^2 - 7x_2 + x_1x_2 + 9 - \ln x_1 - \ln x_2 \qquad (3\text{-}92)$$

corresponding to the contour plot in Fig. 3-54. The optimal solution can be found by solving for the first-order conditions (3-87):

$$\nabla f(x) = \begin{bmatrix} 2x_1 - 4 + x_2 - 1/x_1 \\ 3x_2 - 7 + x_1 - 1/x_2 \end{bmatrix} = 0 \Rightarrow x^* = \begin{bmatrix} 1.3475 \\ 2.0470 \end{bmatrix} \qquad (3\text{-}93)$$

and $f(x^*) = -2.8742$. Checking the second-order conditions leads to

$$\nabla_{xx} f(x^*) = \begin{bmatrix} 2 + 1/(x_1^*)^2 & 1 \\ 1 & 3 + 1/(x_2^*)^2 \end{bmatrix}$$
$$\Rightarrow \nabla_{xx} f(x^*) = \begin{bmatrix} 2.5507 & 1 \\ 1 & 3.2387 \end{bmatrix} \quad \text{(positive definite)} \qquad (3\text{-}94)$$

Now consider the constrained NLP problems

$$\text{Min } (x_1^*)^2 - 4x_1 + 3/2(x_2^*)^2 - 7x_2 + x_1x_2 + 9 - \ln x_1 - \ln x_2$$
$$\text{subject to } 4 - x_1x_2 \leq 0 \qquad (3\text{-}95)$$
$$2x_1 - x_2 = 0$$

that correspond to the plot in Fig. 3-54. The optimal solution can be found by

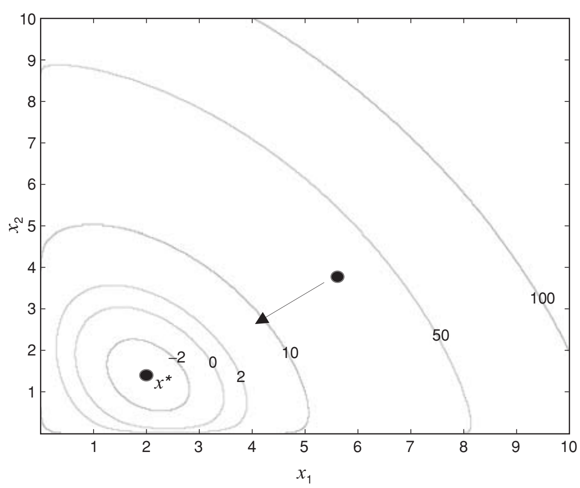

FIG. 3-54 Unconstrained minimum.

applying the first-order KKT conditions (3-88) to (3-90):

$$\nabla L(x, \lambda, \nu) = \nabla f(x) + \nabla h(x)\lambda + \nabla g(x)\nu = \begin{bmatrix} 2x_1 - 4 + x_2 - 1/x_1 \\ 3x_2 - 7 + x_1 - 1/x_2 \end{bmatrix} + \begin{bmatrix} 2 \\ -1 \end{bmatrix}\lambda + \begin{bmatrix} -x_2 \\ -x_1 \end{bmatrix}\nu = 0$$

$$g(x) = 4 - x_1x_2 \le 0, \quad h(x) = 2x_1 - x_2 = 0$$

$$g(x)\,\nu = (4 - x_1x_2)\,\nu, \quad \nu \ge 0 \tag{3-96}$$

$$\Downarrow$$

$$x^* = \begin{bmatrix} 1.4142 \\ 2.8284 \end{bmatrix}, \quad \lambda^* = 1.036, \quad \nu^* = 1.068$$

and $f(x^*) = -1.8421$. Checking the second-order conditions (3-91) leads to

$$\nabla_{xx}L(x^*, \lambda^*, \nu^*) = \nabla_{xx}[f(x^*) + h(x^*)\lambda^* + g(x^*)\nu^*] = \begin{bmatrix} 2 + 1/(x_1)^2 & 1 - \nu \\ 1 - \nu & 3 + 1/(x_2)^2 \end{bmatrix} = \begin{bmatrix} 2.5 & 0.068 \\ 0.068 & 3.125 \end{bmatrix}$$

$$[\nabla h(x^*) \mid \nabla g_A(x^*)]^T p = \begin{bmatrix} 2 & -2.8284 \\ -1 & -1.4142 \end{bmatrix}^T p = 0, \quad p \neq 0$$

However, note that because $[\nabla h(x^*) \mid \nabla g_A(x^*)]$ is nonsingular, there are no nonzero vectors p that satisfy the allowable directions. Hence, the sufficient second-order conditions $[p^T \nabla_{xx} L(x^*, \lambda^*, \nu^*) p > 0$, for all allowable $p]$ are *vacuously satisfied* for this problem.

Convex Cases of NLP Problems Linear programs and quadratic programs are special cases of (3-85) that allow for more efficient solution, based on application of KKT conditions (3-88) through (3-91). Because these are convex problems, any locally optimal solution is a global solution. In particular, if the objective and constraint functions in (3-85) are linear, then the following linear program (LP)

$$\begin{aligned} &\text{Min } c^T x \\ &\text{subject to } Ax = b \\ &\qquad\qquad\quad Cx \le d \end{aligned} \tag{3-97}$$

can be solved in a finite number of steps, and the optimal solution lies at a vertex of the polyhedron described by the linear constraints. This is shown in Fig. 3-56, and in so-called primal degenerate cases, multiple vertices can be alternate optimal solutions, with the same values of the objective function. The standard method to solve (3-97) is the simplex method, developed in the late 1940s (see Dantzig, 1963) although, starting from Karmarkar's discovery in 1984, interior point methods have become quite advanced and competitive for highly constrained problems [Wright, S. J., *Primal-Dual Interior Point Methods*, SIAM, Philadelphia (1996)]. The simplex method proceeds by moving successively from vertex to vertex with improved objective function values. Methods to solve (3-97) are well implemented and widely used, especially in planning and logistical applications. They also form the basis for MILP methods discussed later. Currently, state-of-the-art LP solvers can handle millions of variables and constraints, and the application of further decomposition methods leads to the solution of problems that are two or three orders of magnitude larger than this. See the general references of Hillier and Lieberman (1974) and Edgar et al. (2002) for more details. Also, the interior point method is described below from the perspective of more general NLP problems.

Quadratic programs (QPs) represent a slight modification of (3-97) and can be stated as

$$\begin{aligned} &\text{Min } c^T x + 1/2\, x^T Q x \\ &\text{subject to } Ax = b \\ &\qquad\qquad\quad Cx \le d \end{aligned} \tag{3-98}$$

If the matrix Q is positive semidefinite (positive definite) when projected into the null space of the active constraints, then (3-98) is (strictly) convex and the QP is a global (and unique) minimum. Otherwise, local solutions exist for (3-98), and more extensive global optimization methods are needed to obtain the global solution. Like LPs, convex QPs can be solved in a finite number of steps. However, as seen in Fig. 3-57, these optimal solutions can lie on a vertex, on a constraint boundary, or in the interior. A number of active set strategies have been created that solve the KKT conditions of the QP and incorporate efficient updates of active constraints. Popular methods include null space algorithms, range space methods, and Schur complement methods. As with LPs, QP problems can also be solved with interior point methods [see Wright (1996)].

Solving the General NLP Problem Solution techniques for (3-85) deal with satisfaction of the KKT conditions (3-88) through (3-91). Many NLP solvers are based on successive quadratic programming (SQP) as it allows the construction of a number of NLP algorithms based on the Newton-Raphson method for equation solving (see "Numerical Analysis" section). SQP solvers have been shown to require the fewest function evaluations to solve NLP problems [Schittkowski, K., *Lecture Notes in Economics and Mathematical Systems,* no. 282, Springer-Verlag, Berlin (1987)], and they can be tailored to a broad range of process engineering problems with different structure.

The SQP strategy applies the equivalent of a Newton step to the KKT conditions of the nonlinear programming problem, and this leads to a fast rate of convergence. By adding slack variables s, the first-order KKT conditions can be rewritten as

$$\nabla f(x) + \nabla h(x)\,\lambda + \nabla g(x)\,\nu = 0 \tag{3-99a}$$

$$h(x) = 0 \tag{3-99b}$$

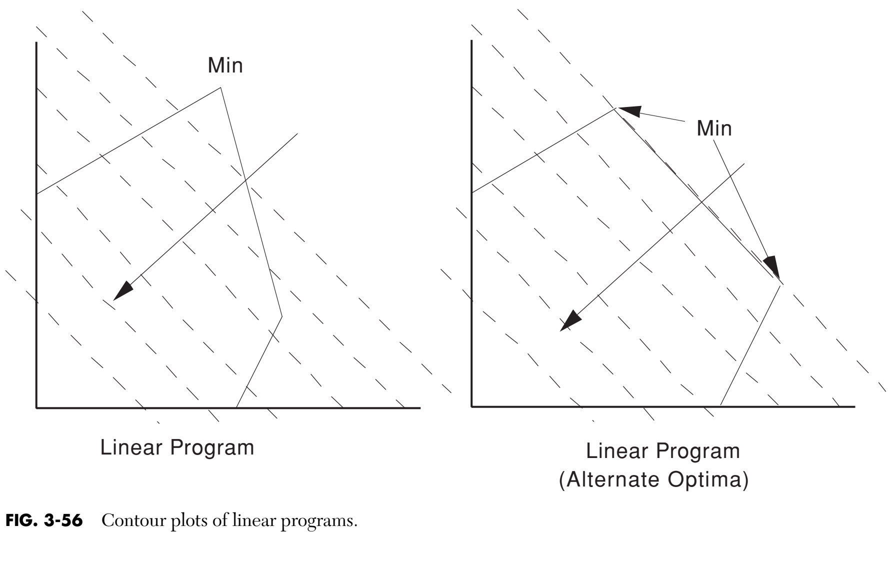

FIG. 3-56 Contour plots of linear programs.

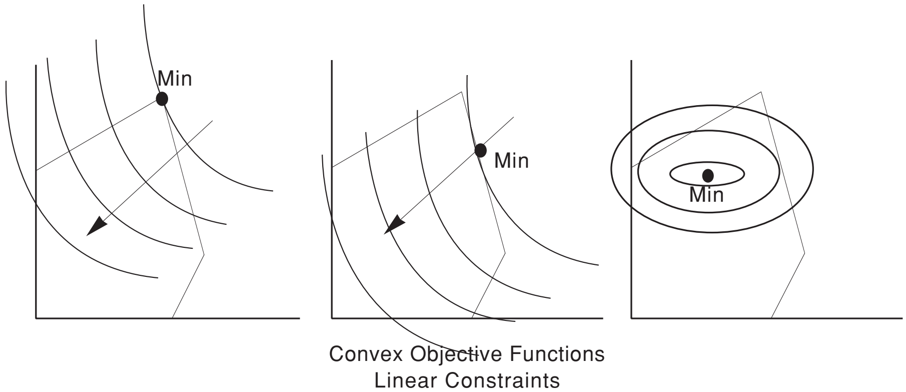

FIG. 3-57 Contour plots of convex quadratic programs.

$$g(x) + s = 0 \quad (3\text{-}99c)$$

$$SVe = 0 \quad (3\text{-}99d)$$

$$(s, \nu) \geq 0 \quad (3\text{-}99e)$$

where $e = [1, 1, \ldots, 1]^T$, $S = \text{diag}\{s\}$, and $V = \text{diag}\{\nu\}$. SQP methods find solutions that satisfy (3-99) by generating Newton-like search directions at iteration k. However, Eqs. (3-99d) and active bounds (3-99e) are dependent at the solution and serve to make the KKT system ill-conditioned near the solution. SQP algorithms treat these conditions in two ways. In the *active set strategy*, discrete decisions are made regarding the active constraint set $i \in I = \{i|g_i(x^*) = 0\}$ and (3-99d) is replaced by $s_i = 0$, $i \in I$, and $\nu_i = 0$, $i \notin I$. Determining the active set is a combinatorial problem, and a straightforward way to determine an estimate of the active set [and to satisfy (3-99e)] is to formulate and solve, at a point x^k, the following QP at iteration k:

$$\begin{aligned} &\text{Min } \nabla f(x^k)^T p + 1/2\, p^T \nabla_{xx} L(x^k, \lambda^k, \nu^k) p \\ &\text{subject to } h(x^k) + \nabla h(x^k)^T p = 0 \\ &\qquad g(x^k) + \nabla g(x^k)^T p + s = 0, \quad s \geq 0 \end{aligned} \quad (3\text{-}100)$$

The KKT conditions of (3-100) are given by

$$\nabla f(x^k) + \nabla^2 L(x^k, \lambda^k, \nu^k) p + \nabla h(x^k)\lambda + \nabla g(x^k)\nu = 0 \quad (3\text{-}101a)$$

$$h(x^k) + \nabla h(x^k)^T p = 0 \quad (3\text{-}101b)$$

$$g(x^k) + \nabla g(x^k)^T p + s = 0 \quad (3\text{-}101c)$$

$$SVe = 0 \quad (3\text{-}101d)$$

$$(s, \nu) \geq 0 \quad (3\text{-}101e)$$

where the Hessian of the Lagrange function $\nabla_{xx} L(x, \lambda, \nu) = \nabla_{xx}[f(x) + h(x)^T\lambda + g(x)^T\nu]$ is calculated directly or through a quasi-Newton approximation (created by differences of gradient vectors). It is easy to show that (3-101a) through (3-101c) correspond to a Newton-Raphson step for (3-99a) through (3-99c) applied at iteration k. Also, selection of the active set is now handled at the QP level by satisfying the conditions (3-101d) and (3-101e). To evaluate and change candidate active sets, QP algorithms apply inexpensive matrix updating strategies to the KKT matrix associated with (3-100). Details of this approach can be found in Nocedal and Wright (1999) and Fletcher (1987).

As alternatives that avoid the combinatorial problem of selecting the active set, interior point (or barrier) methods modify the NLP problem (3-85) to form

$$\begin{aligned} &\text{Min } f(x^k) - \mu \Sigma_i \ln s_i \\ &\text{subject to } h(x^k) = 0 \\ &\qquad g(x^k) + s = 0 \end{aligned} \quad (3\text{-}102)$$

where the solution to (3-103) has $s > 0$ for the penalty parameter $\mu > 0$, and decreasing μ to 0 leads to solution of problem (3-85). The KKT conditions for this problem can be written as

$$\begin{aligned} &\nabla f(x^*) + \nabla h(x^*)\lambda + \nabla g(x^*)\nu = 0 \\ &h(x^*) = 0 \\ &g(x^*) + s = 0 \\ &SVe = \mu e \end{aligned} \quad (3\text{-}103)$$

and for $\mu > 0$, $s > 0$, and $\nu > 0$, Newton steps generated to solve (3-103) are well behaved and analogous to (3-101), with a modification on the right-hand side of (3-101d). A detailed description of this algorithm, called IPOPT, can be found in Wächter and Biegler [*Math. Prog.* **106**(1), 25–57 (2006)].

Both active set and interior point methods possess clear tradeoffs. Interior point methods may require more iterations to solve (3-102) for various values of μ, while active set methods require the solution of the more expensive QP subproblem (3-100). Thus, if there are few inequality constraints or an active set is known (say from a good starting guess, or a known QP solution from a previous iteration), then solving (3-100) is not expensive and the active set method is favored. On the other hand, for problems with many inequality constraints, interior point methods are often faster, as they avoid the combinatorial problem of selecting the active set. This is especially true for large-scale problems and when a large number of bounds are active. Examples that demonstrate the performance of these approaches include the solution of model predictive control (MPC) problems [Rao et al., *J. Optim. Theory Appl.* **99:**723 (1998); Albuquerque et al., *Comp. Chem. Eng.* **23:**283 (1997)] and the solution of large optimal control problems using barrier NLP solvers. For instance, IPOPT allows the solution of problems with more than 1,000,000 variables and up to 50,000 degrees of freedom [see Biegler et al., *Chem. Eng. Sci.* **57**(4):575–593 (2002); Laird et al., *ASCE J. Water Resource Management and Planning* **131**(2):125 (2005)].

Other Gradient-Based NLP Solvers In addition to SQP methods, a number of NLP solvers have been developed and adapted for large-scale problems. Generally these methods require more function evaluations than of SQP methods, but they perform very well when interfaced to optimization modeling platforms, where function evaluations are cheap. All these can be derived from the perspective of applying Newton steps to portions of the KKT conditions.

LANCELOT (Conn et al., 2000) is based on the solution of bound-constrained subproblems. Here an augmented Lagrangian is formed from (3-85) and the following subproblem is solved:

$$\begin{aligned} &\text{Min } f(x) + \lambda^T h(x) + \nu^T[g(x) + s] + 1/2\, \rho \| h(x), g(x) + s \|^2 \\ &\text{subject to } s \geq 0 \end{aligned} \quad (3\text{-}104)$$

The above subproblem can be solved very efficiently for fixed values of the multipliers λ and ν and penalty parameter ρ. Here a gradient projection trust region method is applied. Once subproblem (3-104) is solved, the multipliers and penalty parameter are updated in an outer loop and the cycle repeats until the KKT conditions for (3-85) are satisfied. LANCELOT works best when exact second derivatives are available. This promotes a fast convergence rate in solving each

subproblem and allows a bound-constrained trust region method to exploit directions of negative curvature in the Hessian matrix.

Reduced gradient methods are active set strategies that rely on partitioning the variables and solving (3-99) in a nested manner. Without loss of generality, problem (3-85) can be rewritten as Min $f(z)$ subject to $c(z) = 0$, $a \le z \le b$. Variables are partitioned as nonbasic variables (those fixed to their bounds), basic variables (those that can be solved from the equality constraints), and superbasic variables (those remaining variables between bounds that serve to drive the optimization); this leads to $z^T = [z_N^T, z_B^T, z_S^T]$. This partition is derived from local information and may change over the course of the optimization iterations. The corresponding KKT conditions can be written as

$$\nabla_N f(z) + \nabla_N c(z)\gamma = \beta_a - \beta_b \quad (3\text{-}105a)$$

$$\nabla_B f(z) + \nabla_B c(z)\gamma = 0 \quad (3\text{-}105b)$$

$$\nabla_S f(z) + \nabla_S c(z)\gamma = 0 \quad (3\text{-}105c)$$

$$c(z) = 0 \quad (3\text{-}105d)$$

$$z_{N,j} = a_j \text{ or } b_j, \quad \beta_{a,j} \ge 0, \quad \beta_{b,j} = 0 \text{ or } \beta_{b,j} \ge 0, \quad \beta_{a,j} = 0 \quad (3\text{-}105e)$$

where γ and β are the KKT multipliers for the equality and bound constraints, respectively, and (3-105*e*) replaces the complementarity conditions (3-90). Reduced gradient methods work by nesting equations (3-105*b,d*) within (3-105*a,c*). At iteration k, for fixed values of z_N^k and z_S^k, we can solve for z_B by using (3-105*d*) and for γ by using (3-105*b*). Moreover, linearization of these equations leads to sensitivity information (i.e., constrained derivatives or reduced gradients) that indicates how z_B changes with respect to z_S and z_N. The algorithm then proceeds by updating z_S by using reduced gradients in a Newton-type iteration to solve Eq. (3-105*c*). Following this, bound multipliers β are calculated from (3-105*a*). Over the course of the iterations, if the variables z_B or z_S exceed their bounds or if some bound multipliers β become negative, then the variable partition needs to be changed and Eqs. (3-105) are reconstructed. These reduced gradient methods are embodied in the popular GRG2, CONOPT, and SOLVER codes (Edgar et al., 2002). The SOLVER code has been incorporated into Microsoft Excel. CONOPT [Drud, A., *ORSA J. Computing* **6:** 207–216 (1994)] is an efficient and widely used code in several optimization modelling environments.

MINOS (Murtagh and Saunders, Technical Report SOL 83-20R, Stanford University, 1987) is a well-implemented package that offers a variation on reduced gradient strategies. At iteration k, Eq. (3-105*d*) is replaced by its linearization

$$c(z_N^k, z_B^k, z_S^k) + \nabla_B c(z^k)^T (z_B - z_B^k) + \nabla_S c(z^k)^T (z_S - z_S^k) = 0 \quad (3\text{-}106)$$

and Eqs. (3-105*a–c, e*) are solved with (3-106) as a subproblem by using concepts from the reduced gradient method. At the solution of this subproblem, constraints (3-105*d*) are relinearized and the cycle repeats until the KKT conditions of (3-105) are satisfied. The augmented lagrangian function from (3-104) is used to penalize movement away from the feasible region. For problems with few degrees of freedom, the resulting approach leads to an extremely efficient method even for very large problems. MINOS has been interfaced to a number of modelling systems and enjoys widespread use. It performs especially well on large problems with few nonlinear constraints. However, on highly nonlinear problems it is usually less reliable than other reduced gradient methods.

Algorithmic Details for NLP Methods All the above NLP methods incorporate concepts from the Newton-Raphson method for equation solving. Essential features of these methods are that they provide (1) accurate derivative information to solve for the KKT conditions, (2) stabilization strategies to promote convergence of the Newton-like method from poor starting points, and (3) regularization of the Jacobian matrix in Newton's method (the so-called KKT matrix) if it becomes singular or ill-conditioned.

1. *NLP methods provide first and second derivatives.* The KKT conditions require first derivatives to define stationary points, so accurate first derivatives are essential to determine locally optimal solutions for differentiable NLPs. Moreover, Newton-Raphson methods that are applied to the KKT conditions, as well as the task of checking second-order KKT conditions, necessarily require second-derivative information. (Note that second-order conditions are not checked by methods that do not use second derivatives.) With the recent development of automatic differentiation tools, many modeling and simulation platforms can provide exact first and second derivatives for optimization. When second derivatives are available for the objective or constraint functions, they can be used directly in LANCELOT as well as SQP and reduced gradient methods. Otherwise, on problems with few superbasic variables, both reduced gradient methods and SQP methods [with reduced gradient methods applied to the QP subproblem (3-100)] can benefit from positive definite quasi-Newton approximations [Nocedal and Wright (1999)] applied to reduced second-derivative quantities (the so-called reduced Hessian). Finally, for problems with least squares functions (see "Statistics" subsection), as in data reconciliation, parameter estimation, and model predictive control, one can often assume that the values of the objective function and its gradient at the solution are vanishingly small. Under these conditions, one can show that the multipliers (λ, ν) also vanish and $\nabla_{xx}L(x, \lambda, \nu)$ can be substituted by $\nabla_{xx}f(x^*)$. This *Gauss-Newton approximation* has been shown to be very efficient for the solution of least squares problems [see Nocedal and Wright (1999)].

2. *Line search and trust region methods promote convergence from poor starting points*. These are commonly used with the search directions calculated from NLP subproblems such as (3-100). In a *trust region approach*, the constraint $\|p\| \le \Delta$ is added and the iteration step is taken if there is sufficient reduction of some merit function (e.g., the objective function weighted with some measure of the constraint violations). The size of the trust region Δ is adjusted based on the agreement of the reduction of the actual merit function compared to its predicted reduction from the subproblem (see Conn et al., 2000, for details). Such methods have strong global convergence properties and are especially appropriate for ill-conditioned NLPs. This approach has been applied in the KNITRO code [Byrd, Hribar, and Nocedal, *SIAM J. Optimization* **9**(4):877 (1999)]. *Line search methods* can be more efficient on problems with reasonably good starting points and well-conditioned subproblems, as in real-time optimization. Typically, once a search direction is calculated from (3-100), or other related subproblem, a step size $\alpha \in (0, 1)$ is chosen so that $x^k + \alpha p$ leads to a sufficient decrease of a merit function. As a recent alternative, a novel *filter* stabilization strategy (for both line search and trust region approaches) has been developed based on a bicriterion minimization, with the objective function and constraint infeasibility as competing objectives [Fletcher et al., *SIAM J. Optimization* **13**(3):635 (2002)]. This method often leads to better performance than that based on merit functions.

3. *Regularization of the KKT matrix for the NLP subproblem is essential for good performance of general-purpose algorithms*. For instance, to obtain a unique solution to (3-100), active constraint gradients must be full rank and the Hessian matrix, when projected into the null space of the active constraint gradients, must be positive definite. These properties may not hold far from the solution, and corrections to the Hessian in SQP may be necessary (see Fletcher, 1987). Regularization methods ensure that subproblems such as (3-100) remain well-conditioned; they include addition of positive constants to the diagonal of the Hessian matrix to ensure its positive definiteness, judicious selection of active constraint gradients to ensure that they are linearly independent, and scaling the subproblem to reduce the propagation of numerical errors. Often these strategies are heuristics built into particular NLP codes. While quite effective, most of these heuristics do not provide convergence guarantees for general NLPs.

From the conceptual descriptions as well as algorithmic details given above, it is clear that NLP solvers are complex algorithms that have required considerable research and development to turn them into reliable and efficient software tools. Practitioners who are confronted with engineering optimization problems should therefore leverage these efforts, rather than write their own codes. Table 3-4 presents a sampling of available NLP codes that represent the above classifications. Much more information on these and other codes can be found on the NEOS server (www-neos.mcs.anl.gov) and the NEOS Software Guide: http://www-fp.mcs.anl.gov/otc/Guide/SoftwareGuide.

TABLE 3-4 Representative NLP Solvers

Method	Algorithm type	Stabilization	Second-order information
CONOPT (Drud, 1994)	Reduced gradient	Line search	Exact and quasi-Newton
GRG2 (Edgar et al., 2002)	Reduced gradient	Line search	Quasi-Newton
IPOPT	SQP, barrier	Line search	Exact
KNITRO (Byrd et al., 1997)	SQP, barrier	Trust region	Exact and quasi-Newton
LANCELOT	Augmented lagrangian, bound constrained	Trust region	Exact and quasi-Newton
LOQO	SQP, barrier	Line search	Exact
MINOS	Reduced gradient, augmented lagrangian	Line search	Quasi-Newton
NPSOL	SQP, active set	Line search	Quasi-Newton
SNOPT	Reduced space SQP, active set	Line search	Quasi-Newton
SOCS	SQP, active set	Line search	Exact
SOLVER	Reduced gradient	Line search	Quasi-Newton
SRQP	Reduced space SQP, active set	Line search	Quasi-Newton

OPTIMIZATION METHODS WITHOUT DERIVATIVES

A broad class of optimization strategies does not require derivative information. These methods have the advantage of easy implementation and little prior knowledge of the optimization problem. In particular, such methods are well suited for "quick and dirty" optimization studies that explore the scope of optimization for new problems, prior to investing effort for more sophisticated modeling and solution strategies. Most of these methods are derived from heuristics that naturally spawn numerous variations. As a result, a very broad literature describes these methods. Here we discuss only a few important trends in this area.

Classical Direct Search Methods Developed in the 1960s and 1970s, these methods include one-at-a-time search and methods based on experimental designs (EVOP). At that time, these direct search methods were the most popular optimization methods in chemical engineering. Methods that fall into this class include the pattern search of Hooke and Jeeves [*J. ACM* **8:**212 (1961)], the conjugate direction method of Powell (1964), simplex and complex searches, in particular Nelder-Mead [*Comput. J.* **7:** 308 (1965)], and the adaptive random search methods of Luus-Jaakola [*AIChE J.* **19:** 760 (1973)], Goulcher and Cesares Long [*Comp. Chem. Engr.* **2:** 23 (1978)] and Banga et al. [in *State of the Art in Global Optimization*, C. Floudas and P. Pardalos (eds.), Kluwer, Dordrecht, p. 563 (1996)]. All these methods require only objective function values for unconstrained minimization. Associated with these methods are numerous studies on a wide range of process problems. Moreover, many of these methods include heuristics that prevent premature termination (e.g., directional flexibility in the complex search as well as random restarts and direction generation). To illustrate these methods, Fig. 3-58 illustrates the performance of a pattern search method as well as a random search method on an unconstrained problem.

Simulated Annealing This strategy is related to random search methods and derives from a class of heuristics with analogies to the motion of molecules in the cooling and solidification of metals [Laarhoven and Aarts, *Simulated Annealing: Theory and Applications,* Reidel Publishing, Dordrecht (1987)]. Here a temperature parameter θ can be raised or lowered to influence the probability of accepting points that do not improve the objective function. The method starts with a base point x and objective value $f(x)$. The next point x' is chosen at random from a distribution. If $f(x') < f(x)$, the move is accepted with x' as the new point. Otherwise, x' is accepted with probability $p(\theta, x', x)$. Options include the Metropolis distribution $p(\theta, x, x') = \exp\{-[f(x')-f(x)]/\theta\}$ and the Glauber distribution, $p(\theta, x, x') = \exp\{-[f(x')-f(x)]/\theta\}/(1 + \exp\{-[f(x')-f(x)]/\theta\})$. The θ parameter is then reduced, and the method continues until no further progress is made.

Genetic Algorithms This approach, first proposed in Holland, J. H., *Adaptations in Natural and Artificial Systems* [University of Michigan Press, Ann Arbor (1975)], is based on the analogy of improving a population of solutions through modifying their gene pool. It also has similar performance characteristics as random search methods and simulated annealing. Two forms of genetic modification, crossover or mutation, are used and the elements of the optimization vector **x** are represented as binary strings. Crossover deals with random swapping of vector elements (among parents with highest objective function values or other rankings of population) or any linear combinations of two parents. Mutation deals with the addition of a random variable to elements of the vector. Genetic algorithms (GAs) have seen widespread use in process engineering, and a number of codes are available. Edgar et al. (2002) describe a related GA that is available in MS Excel.

Derivative-free Optimization (DFO) In the past decade, the availability of parallel computers and faster computing hardware and the need to incorporate complex simulation models within optimization studies have led a number of optimization researchers to reconsider classical direct search approaches. In particular, Dennis and Torczon [*SIAM J. Optim.* **1:** 448 (1991)] developed a multidimensional search algorithm that extends the simplex approach of Nelder

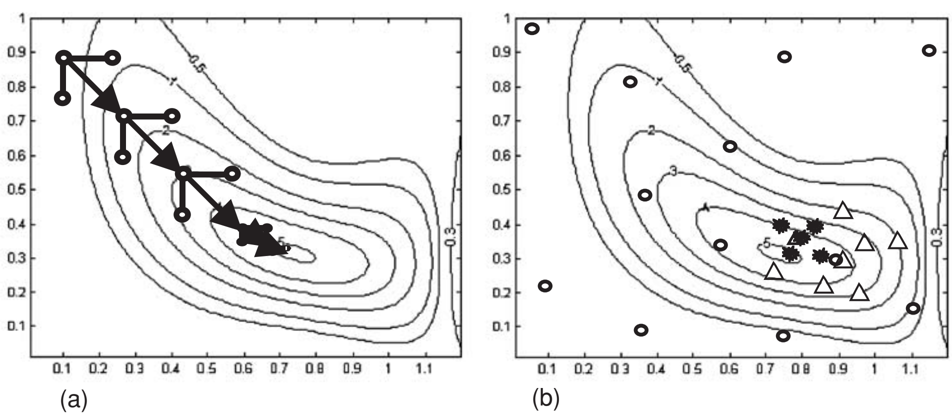

FIG. 3-58 Examples of optimization methods without derivatives. (*a*) Pattern search method. (*b*) Random search method. ○, first phase; Δ, second phase; ✲, third phase.

and Mead (1965). They note that the Nelder-Mead algorithm fails as the number of variables increases, even for very simple problems. To overcome this, their multidimensional pattern search approach combines reflection, expansion, and contraction steps that act as line search algorithms for a number of linear independent search directions. This approach is easily adapted to parallel computation, and the method can be tailored to the number of processors available. Moreover, this approach converges to locally optimal solutions for unconstrained problems and observes an unexpected performance synergy when multiple processors are used. The work of Dennis and Torczon (1991) has spawned considerable research on the analysis and code development for DFO methods. For instance, Conn et al. [*Math. Programming,* Series B, **79**(3)**:** 397 (1997)] constructed a multivariable DFO algorithm that uses a surrogate model for the objective function within a trust region method. Here points are sampled to obtain a well-defined quadratic interpolation model, and descent conditions from trust region methods enforce convergence properties. A number of trust region methods that rely on this approach are reviewed in Conn et al. (1997). Moreover, a number of DFO codes have been developed that lead to black box optimization implementations for large, complex simulation models [see Audet and Dennis, *SIAM J. Optim.***13:** 889 (2003); Kolda et al., *SIAM Rev.* **45**(3): 385 (2003)]. These include the DAKOTA package at Sandia National Lab (Eldred, 2002; http://endo.sandia.gov/DAKOTA/software.html) and FOCUS developed at Boeing Corporation (Booker et al., CRPC Technical Report 98739, Rice University, February 1998).

Direct search methods are easy to apply to a wide variety of problem types and optimization models. Moreover, because their termination criteria are not based on gradient information and stationary points, they are more likely to favor the search for globally optimal rather than locally optimal solutions. These methods can also be adapted easily to include integer variables. However, no rigorous convergence properties to globally optimal solutions have yet been discovered. Also, these methods are best suited for unconstrained problems or for problems with simple bounds. Otherwise, they may have difficulties with constraints, as the only options open for handling constraints are equality constraint elimination and addition of penalty functions for inequality constraints. Both approaches can be unreliable and may lead to failure of the optimization algorithm. Finally, the performance of direct search methods scales poorly (and often exponentially) with the number of decision variables. While performance can be improved with the use of parallel computing, these methods are rarely applied to problems with more than a few dozen decision variables.

GLOBAL OPTIMIZATION

Deterministic optimization methods are available for nonconvex nonlinear programming problems of the form (3-85) that guarantee convergence to the global optimum. More specifically, one can show under mild conditions that they converge to an ϵ distance to the global optimum in a finite number of steps. These methods are generally more expensive than local NLP methods, and they require the exploitation of the structure of the nonlinear program.

Because there are no optimality conditions like the KKT conditions for global optimization, these methods work by first partitioning the problem domain (i.e., containing the feasible region) into subregions. Upper bounds on the objective function are computed over all subregions of the problem. In addition, lower bounds can be derived from convex relaxations of the objective function and constraints for each subregion. The algorithm then proceeds to eliminate all subregions that have infeasible constraint relaxations or lower bounds that are greater than the least upper bound. After this, the remaining regions are further partitioned to create new subregions, and the cycle continues until the upper and lower bounds converge.

This basic concept leads to a wide variety of global algorithms, with the following features that can exploit different problem classes. *Bounding* strategies relate to the calculation of upper and lower bounds. For the former, any feasible point or, preferably, a locally optimal point in the subregion can be used. For the lower bound, convex relaxations of the objective and constraint functions are derived. The *refining* step deals with the construction of partitions in the domain and further partitioning them during the search process. Finally, the *selection* step decides on the order of exploring the open subregions.

For simplicity, consider the problem Min $f(x)$ subject to $g(x) \le 0$ where each function can be defined by additive terms. Convex relaxations for $f(x)$ and $g(x)$ can be derived in the following ways:

- Convex additive terms remain unmodified in these functions.
- Concave additive unary terms are replaced by a linear underestimating function that matches the term at the bounds of the subregion.
- Nonconvex polynomial terms can be replaced by a set of binary terms, with new variables introduced to define the higher-order polynomials.
- Binary terms can be relaxed by using the McCormick underestimator; e.g., the binary term xz is replaced by a new variable w and linear inequality constraints

$$\begin{aligned} w &\ge x_l z + z_l x - x_l z_l \\ w &\ge x_u z + z_u x - x_u z_u \\ w &\le x_u z + z_l x - x_u z_l \\ w &\le x_l z + z_u x - x_l z_u \end{aligned} \tag{3-107}$$

where the subregions are defined by $x_l \le x \le x_u$ and $z_l \le z \le z_u$. Thus the feasible region and the objective function are replaced by convex envelopes to form relaxed problems.

Solving these convex relaxed problems leads to global solutions that are lower bounds to the NLP in the particular subregion. Finally, we see that gradient-based NLP solvers play an important role in global optimization algorithms, as they often yield the lower and upper bounds for the subregions. The *spatial branch and bound* global optimization algorithm can therefore be given by the following steps:

0. Initialize algorithm: calculate upper and lower bounds over the entire (relaxed) feasible region.

For iteration k with a set of partitions M_{kj} and bounds in each subregion f_{Lj} and f_{Uj}:

1. *Bound.* Define best upper bound: $f_U = \min_j f_{Uj}$ and delete (fathom) all subregions j with lower bounds $f_{Lj} \ge f_U$. If the remaining subregions satisfy $f_{Lj} \ge f_U - \varepsilon$, stop.
2. *Refine.* Divide the remaining active subregions into partitions $M_{k,j1}$ and $M_{k,j2}$. (Many branching rules are available for this step.)
3. *Select.* Solve the convex relaxed NLP in the new partitions to obtain f_{Lj1} and f_{Lj2}. Delete the partition if there is no feasible solution.
4. *Update.* Obtain upper bounds f_{Uj1} and f_{Uj2} to new partitions, if present. Set $k = k+1$, update partition sets, and go to step 1.

Example To illustrate the spatial branch and bound algorithm, consider the global solution of

$$\text{Min} f(x) = \frac{5}{2}x^4 - 20x^3 + 55x^2 - 57x, \quad \text{subject to} \quad 0.5 \le x \le 2.5 \tag{3-108}$$

As seen in Fig. 3-59, this problem has local solutions at $x^* = 2.5$ and at $x^* = 0.8749$. The latter is also the global solution with $f(x^*) = -19.7$. To find the global solution, we note that all but the $-20x^3$ term in (3-108) are convex, so we replace this term by a new variable and a linear underestimator within a particular subregion, i.e.,

$$\begin{aligned} &\text{Min} f_L(x) = \frac{5}{2}x^4 - 20w + 55x^2 - 57x \\ &\text{subject to } x_l \le x \le x_u \\ &w = x_l^3 \frac{x_u - x}{x_u - x_l} + x_u^3 \frac{x - x_l}{x_u - x_l} \end{aligned} \tag{3-109}$$

In Fig. 3-59 we also propose subregions that are created by simple bisection partitioning rules, and we use a "loose" bounding tolerance of $\varepsilon = 0.2$. In each partition the lower bound f_L is determined by (3-109) and the upper bound f_U is determined by the local solution of the original problem in the subregion. Figure 3-60 shows the progress of the spatial branch and bound algorithm as the partitions are refined and the bounds are updated. In Fig. 3-60, note the definitions of the partitions for the nodes, and the sequence numbers in each node that show the order in which the partitions are

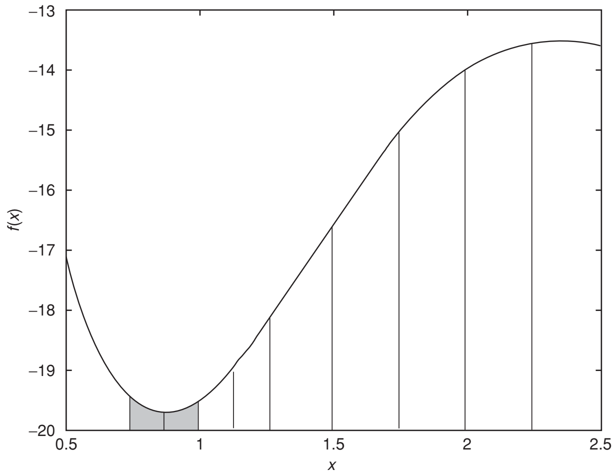

FIG. 3-59 Global optimization example with partitions.

processed. The grayed partitions correspond to the deleted subregions, and at termination of the algorithm we see that $f_{Lj} \geq f_U - \varepsilon$ (that is, $-19.85 \geq -19.7 - 0.2$), with the gray subregions in Fig. 3-59 still active. Further partitioning in these subregions will allow the lower and upper bounds to converge to a tighter tolerance.

Note that a number of improvements can be made to the bounding, refinement, and selection strategies in the algorithm that accelerate the convergence of this method. A comprehensive discussion of all these options can be found in Floudas (2000), Tawarlamani and Sahinidis (2002), and Horst and Tuy (1993). Also, a number of efficient global optimization codes have recently been developed, including αBB, BARON, LGO, and OQNLP. An interesting numerical comparison of these and other codes can be found in Neumaier et al., *Math. Prog. B* **103**(2): 335(2005).

MIXED INTEGER PROGRAMMING

Mixed integer programming deals with both discrete and continuous decision variables. For the purpose of illustration we consider discrete decisions as binary variables, that is, $y_i = 0$ or 1, and we consider the mixed integer problem (3-84). Unlike in local optimization methods, there are no optimality conditions, such as the KKT conditions, that can be applied directly. Instead, as in the global optimization methods, a systematic search of the solution space, coupled with upper and lower bounding information, is applied. As with global optimization problems, large mixed integer programs can be expensive to solve, and some care is needed in the problem formulation.

Mixed Integer Linear Programming If the objective and constraint functions are all linear, then (3-84) becomes a mixed integer linear programming problem given by

$$\begin{aligned} &\text{Min } Z = a^T x + c^T y \\ &\text{subject to } Ax + By \leq b \\ &\qquad x \geq 0,\ y \in \{0, 1\}^t \end{aligned} \tag{3-110}$$

Note that if we relax the t binary variables by the inequalities $0 \leq y \leq 1$, then (3-110) becomes a linear program with a (global) solution that is a lower bound to the MILP (3-110). There are specific MILP classes where the LP relaxation of (3-110) has the same solution as the MILP. Among these problems is the well-known *assignment problem*. Other MILPs that can be solved with efficient special-purpose methods are the *knapsack* problem, the *set covering* and *set partitioning* problems, and the *traveling salesperson* problem. See Nemhauser and Wolsey (1988) for a detailed treatment of these problems.

More generally, MILPs are solved with branch and bound algorithms, similar to the spatial branch and bound method of the previous section, that explore the search space. As seen in Fig. 3-61, binary variables are used to define the search tree, and a number of bounding properties can be noted from the structure of (3-110).

Upper bounds on the objective function can be found from any feasible solution to (3-110), with y set to integer values. These can be found at the bottom or "leaf" nodes of a branch and bound tree (and sometimes at intermediate nodes as well). The top, or root, node in

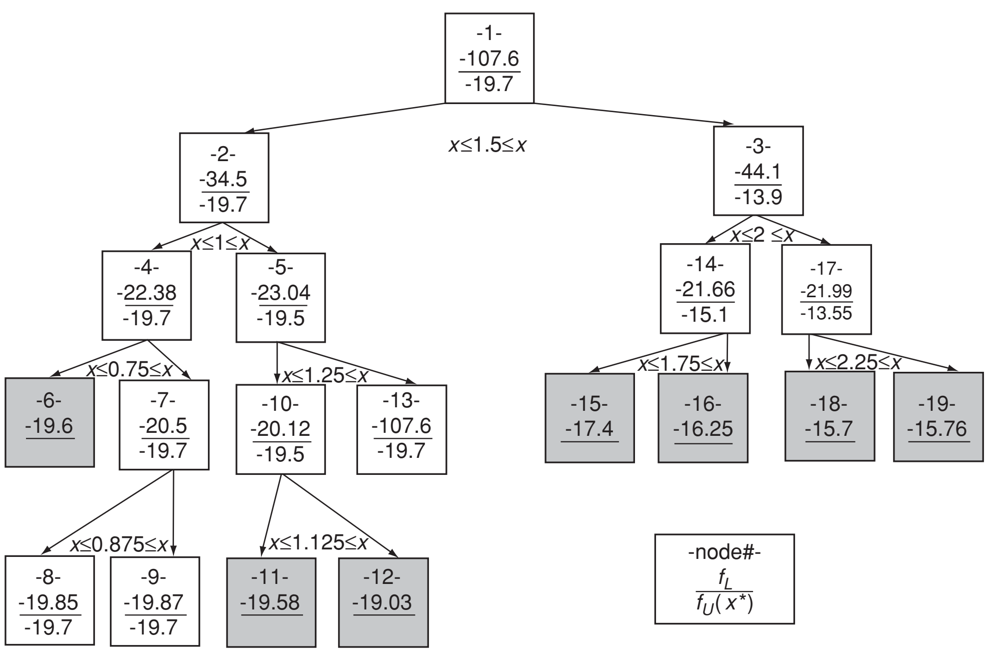

FIG. 3-60 Spatial branch and bound sequence for global optimization example.

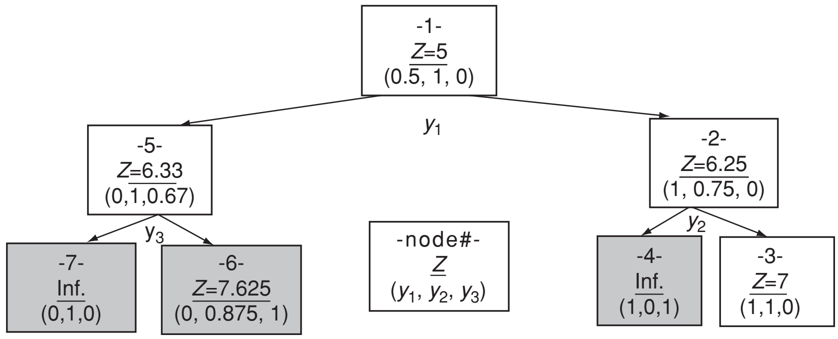

FIG. 3-61 Branch and bound sequence for MILP example.

the tree is the solution to the linear programming relaxation of (3-110); this is a lower bound to (3-110). On the other hand, as one proceeds down the tree with a partial assignment of the binary variables, a lower bound for any leaf node in that branch can be found from solution of the linear program at this intermediate node with the remaining binary variables relaxed. This leads to the following properties:

- Any intermediate node with an infeasible LP relaxation has infeasible leaf nodes and can be fathomed (i.e., all remaining children of this node can be eliminated).
- If the LP solution at an intermediate node is not less than an existing integer solution, then the node can be fathomed.

These properties lead to pruning of the search tree. Branching then continues in the tree until the upper and lower bounds converge.

This basic concept leads to a wide variety of MILP algorithms with the following features. *LP solutions* at intermediate nodes are relatively easy to calculate with the simplex method. If the solution of the parent node is known, multiplier information from this solution can be used to calculate (via a very efficient pivoting operation) the LP solution at the child node. *Branching strategies* to navigate the tree take a number of forms. More common *depth-first strategies* expand the most recent node to a leaf node or infeasible node and then backtrack to other branches in the tree. These strategies are simple to program and require little storage of past nodes. On the other hand, *breadth-first strategies* expand all the nodes at each level of the tree, select the node with the lowest objective function, and then proceed until the leaf nodes are reached. Here, more storage is required but generally fewer nodes are evaluated than in depth-first search. In addition, *selection of binary variable for branching* is based on a number of criteria, including choosing the variable with the relaxed value closest to 0 or 1, or the one leading to the largest change in the objective. Additional description of these strategies can be found in Biegler et al. (1997) and Nemhauser and Wolsey (1988).

Example To illustrate the branch and bound approach, we consider the MILP:

$$\begin{aligned} &\text{Min } Z = x + y_1 + 2y_2 + 3y_3 \\ &\text{subject to } -x + 3y_1 + y_2 + 2y_3 \le 0 \\ &\qquad -4y_1 - 8y_2 - 3y_3 \le -10 \\ &\qquad x \ge 0,\ y_1, y_2, y_3 = \{0, 1\} \end{aligned} \tag{3-111}$$

The solution to (3-111) is given by $x = 4$, $y_1 = 1$, $y_2 = 1$, $y_3 = 0$, and Z = 7. Here we use a depth-first strategy and branch on the variables closest to 0 or 1. Fig. 3-61 shows the progress of the branch and bound algorithm as the binary variables are selected and the bounds are updated. The sequence numbers for each node in Fig. 3-61 show the order in which they are processed. The grayed partitions correspond to the deleted nodes, and at termination of the algorithm we see that Z = 7 and an integer solution is obtained at an intermediate node where coincidentally $y_3 = 0$.

A number of improvements that can be made to the branching rules will accelerate the convergence of this method. A comprehensive discussion of all these options can be found in Nemhauser and Wolsey (1988). Also, a number of efficient MILP codes have recently been developed, including CPLEX, OSL, XPRESS, and ZOOM. All these serve as excellent large-scale optimization codes as well. A detailed description and availability of these and other MILP solvers can be found in the NEOS Software Guide: http://www-fp.mcs.anl.gov/otc/Guide/SoftwareGuide.

Mixed Integer Nonlinear Programming Without loss of generality, we can rewrite the MINLP in (3-84) as:

$$\begin{aligned} &\text{Min } Z = f(x) + c^T y \\ &\text{subject to } g(x) + By \le b \\ &\qquad x \ge 0,\ y \in \{0, 1\}^t \end{aligned} \tag{3-112}$$

where the binary variables are kept as separate linear terms. We develop several MINLP solution strategies by drawing from the material in the preceding sections. MINLP strategies can be classified into two types. The first deals with nonlinear extensions of the branch and bound method discussed above for MILPs. The second deals with outer approximation decomposition strategies that provide lower and upper bounding information for convergence.

Nonlinear Branch and Bound The MINLP (3-112) can be solved in a similar manner to (3-110). If the functions $f(x)$ and $g(x)$ in (3-112) are convex, then direct extensions to the branch and bound method can be made. A relaxed NLP can be solved at the root node, upper bounds to the solution of (3-112) can be found at the leaf nodes, and the bounding properties due to NLP solutions at intermediate nodes still hold. However, this approach is more expensive than the corresponding MILP method. First, NLPs are more expensive than LPs to solve. Second, unlike with relaxed LP solutions, NLP solutions at child nodes cannot be updated directly from solutions at parent nodes. Instead, the NLP needs to be solved again (but one hopes with a better starting guess). The NLP branch and bound method is used in the SBB code interfaced to GAMS. In addition, Leyffer, [*Comput. Optim. Appl.* **18:** 295 (2001)] proposed a hybrid MINLP strategy nested within an SQP algorithm. At each iteration, a mixed integer quadratic program is formed, and a branch and bound algorithm is executed to solve it.

If $f(x)$ and $g(x)$ are nonconvex, additional difficulties can occur. In this case, nonunique, local solutions can be obtained at intermediate nodes, and consequently lower bounding properties would be lost. In addition, the nonconvexity in $g(x)$ can lead to locally infeasible problems at intermediate nodes, even if feasible solutions can be found in the corresponding leaf node. To overcome problems with nonconvexities, global solutions to relaxed NLPs can be solved at the intermediate nodes. This preserves the lower bounding information and allows nonlinear branch and bound to inherit the convergence properties from the linear case. However, as noted above, this leads to much more expensive solution strategies.

Outer Approximation Decomposition Methods Again, we consider the MINLP (3-112) with convex $f(x)$ and $g(x)$. Note that the NLP with binary variables fixed at $\bar{y}$

$$\begin{aligned} &\text{Min } Z = f(x) + c^T \bar{y} \\ &\text{subject to } g(x) + B\bar{y} \le b \\ &\qquad x \ge 0 \end{aligned} \tag{3-113}$$

if feasible, leads to a solution that is an upper bound on the MINLP

solution. In addition, linearizations of convex functions lead to underestimation of the function itself:

$$\phi(x) \geq \phi(x^k) + \nabla\phi(x^k)^T(x - x^k) \qquad (3\text{-}114)$$

Consequently, linearization of (3-112) at a point x^k, to form the problem

$$\begin{aligned} &\text{Min } Z = f(x^k) + \nabla f(x^k)^T(x - x^k) + c^T y \\ &\text{subject to } g(x^k) + \nabla g(x^k)^T(x - x^k) + By \leq b \qquad (3\text{-}115) \\ &x \geq 0,\ y \in \{0, 1\}^t \end{aligned}$$

leads to overapproximation of the feasible region and underapproximation of the objective function in (3-112). Consequently, solution of (3-115) is a lower bound to the solution of (3-112). Adding more linearizations from other points does not change the bounding property, so for a set of points x^l, $l = 1, \ldots, k$, the problem

$$\begin{aligned} &\text{Min } Z = \alpha \\ &\left.\begin{aligned} \text{subject to } \alpha &\geq f(x^l) + \nabla f(x^l)^T(x - x^l) + c^T y \\ g(x^l) &+ \nabla g(x^l)^T(x - x^l) + By \leq b \end{aligned}\right\} \quad l = 1, \ldots, k \qquad (3\text{-}116) \\ &x \geq 0,\ y \in \{0,1\}^t \end{aligned}$$

where α is a scalar variable, still has a solution that is a lower bound to (3-112). The outer approximation strategy is depicted in Fig. 3-62.

The outer approximation algorithm [Duran, M., and I. E. Grossmann, *Math. Programming* **36:** 307 (1986)] begins by initializing the problem, either with a predetermined starting guess or by solving a relaxed NLP based on (3-112). An upper bound to the solution is then generated by fixing the binary variables to their current values y^k and solving the NLP (3-113). This solution determines the continuous variable values x^k for the MILP (3-116). [If (3-113) is an infeasible problem, any point may be chosen for x^k, or the linearizations could be omitted.] Note that this MILP also contains linearizations from previous solutions of (3-113). Finally, the integer cut $\sum_i |y_i - y_i^k| \geq 1$ is added to (3-116) to avoid revisiting previously encountered values of binary variables. (In convex problems the integer cut is not needed, but it helps to accelerate solution of the MILP.) Solution of (3-116) yields new values of y and (without the integer cut) must lead to a lower bound to the solution of (3-112). Consequently, if the objective function of the lower bounding MILP is greater than the least upper bound determined in solutions of (3-113), then the algorithm terminates. Otherwise, the new values of y are used to solve the next NLP (3-113).

Compared to nonlinear branch and bound, the outer approximation algorithm usually requires very few solutions of the MILP and NLP subproblems. This is especially advantageous on problems where the NLPs are large and expensive to solve. Moreover, there are two variations of outer approximation that may be suitable for particular problem types:

In *Generalized Benders Decomposition* (GBD) [see Sahinidis and Grossmann, *Computers and Chem. Eng.* **15:** 481 (1991)], the lower

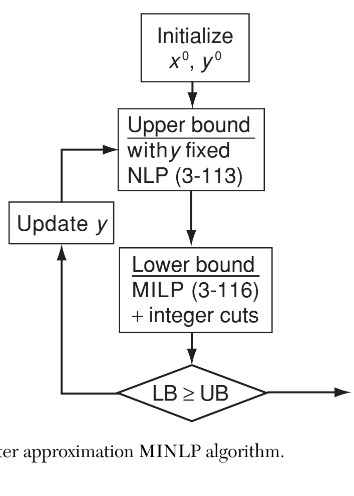

FIG. 3-62 Outer approximation MINLP algorithm.

bounding problem in Fig. 3-62 is replaced by the following MILP:

$$\begin{aligned} &\text{Min } \alpha \\ &\left.\begin{aligned} \text{subject to } \alpha &\geq f(x^l) + c^T y + \nu^{lT}[g(x^l) + By] \\ \sum_i |y_i &- y_i^l| \geq 1 \end{aligned}\right\} \quad l = 1, \ldots, k \qquad (3\text{-}117) \end{aligned}$$

where ν^l is the vector of KKT multipliers from the solution of (3-113) at iteration l. This MILP can be derived through a reformulation of the MILP used in Fig. 3-62 with the *inactive constraints* from (3-113) dropped. Solution of (3-117) leads to a weaker lower bound than (3-116), and consequently, more solutions of the NLP and MILP subproblems are needed to converge to the solution. However, (3-117) contains only a single continuous variable and far fewer inequality constraints and is much less expensive to solve than (3-116). Thus, GBD is favored over outer approximation if (3-113) is relatively inexpensive to solve or solution of (3-116) is too expensive.

The *extended cutting plane* (ECP) algorithm [Westerlund and Pettersson, *Computers and Chem. Engng.* **19:** S131 (1995)] is complementary to GBD. While the lower bounding problem in Fig. 3-62 remains essentially the same, the continuous variables x^k are chosen from the MILP solution and the NLP (3-113) is replaced by a simple evaluation of the objective and constraint functions. As a result, only MILP problems [(3-116) plus integer cuts] need be solved. Consequently, the ECP approach has weaker upper bounds than outer approximation and requires more MILP solutions. It has advantages over outer approximation when the NLP (3-113) is expensive to solve.

Additional difficulties arise for the outer approximation algorithm and its GBD and ECP extensions when neither $f(x)$ nor $g(x)$ is convex. Under these circumstances, the lower bounding properties resulting from the linearization and formulation of the MILP subproblem are lost, and the MILP solution may actually exclude the solution of (3-112). Hence, these algorithms need to be applied with care to nonconvex problems. To deal with nonconvexities, one can relax the linearizations in (3-116) through the introduction of additional *deviation variables* that can be penalized in the objective function. Alternately, the linearizations in (3-116) can be replaced by valid underestimating functions, such as those derived for global optimization [e.g., (3-107)]. However, this requires knowledge of structural information for (3-112) and may lead to weak lower bounds in the resulting MILP.

Finally, the performance of both MILP and MINLP algorithms is strongly dependent on the problem formulations (3-110) and (3-112). In particular, the efficiency of the approach is impacted by the lower bounds produced by the relaxation of the binary variables and subsequent solution of the linear program in the branch and bound tree. A number of approaches have been proposed to improve the quality of the lower bounds, including these:

- Logic-based methods such as *generalized disjunctive programming* (GDP) can be used to formulate MINLPs with fewer discrete variables that have tighter relaxations. Moreover, the imposition of logic-based constraints prevents the generation of unsuitable alternatives, leading to a less expensive search. In addition, constrained logic programming (CLP) methods offer an efficient search alternative to MILP solvers for highly combinatorial problems. See Raman and Grossmann, *Computers and Chem. Engng.* **18**(7): 563 (1994) for more details.
- Convex hull formulations of MILPs and MINLPs lead to relaxed problems that have much tighter lower bounds. This leads to the examination of far fewer nodes in the branch and bound tree. See Grossmann and Lee, *Comput. Optim. Applic.* **26:** 83 (2003) for more details.
- *Reformulation* and *preprocessing* strategies including bound tightening of the variables, coefficient reduction, lifting facets, and special ordered set constraints frequently lead to improved lower bounds and significant performance improvements in mixed integer programming algorithms.

A number of efficient codes are available for the solution of MINLPs. These include the AlphaECP, BARON, DICOPT, MINLP, and SBB solvers; descriptions of these can be found on the http://www.gamsworld.org/minlp/solvers.htm web site.

DEVELOPMENT OF OPTIMIZATION MODELS

The most important aspect to a successful optimization study is the formulation of the optimization model. These models must reflect the real-world problem so that meaningful optimization results are obtained; they also must satisfy the properties of the problem class. For instance, NLPs addressed by gradient-based methods need to have functions that are defined in the variable domain and have bounded and continuous first and second derivatives. In mixed integer problems, proper formulations are also needed to yield good lower bounds for efficient search. With increased understanding of optimization methods and the development of efficient and reliable optimization codes, optimization practitioners now focus on the *formulation* of optimization models that are realistic, well posed, and inexpensive to solve. Finally, convergence properties of NLP, MILP, and MINLP solvers require accurate first (and often second) derivatives from the optimization model. If these contain numerical errors (say, through finite difference approximations), then the performance of these solvers can deteriorate considerably. As a result of these characteristics, modeling platforms are essential for the formulation task. These are classified into two broad areas: optimization modeling platforms and simulation platforms with optimization.

Optimization modeling platforms provide general-purpose interfaces for optimization algorithms and remove the need for the user to interface to the solver directly. These platforms allow the general formulation for all problem classes discussed above with direct interfaces to state-of-the-art optimization codes. Three representative platforms are the GAMS (General Algebraic Modeling Systems), AMPL (A Mathematical Programming Language), and AIMMS (Advanced Integrated Multidimensional Modeling Software). All three require problem model input via a declarative modeling language and provide exact gradient and Hessian information through automatic differentiation strategies. Although it is possible, these platforms were not designed to handle externally added procedural models. As a result, these platforms are best applied on optimization models that can be developed entirely within their modeling framework. Nevertheless, these platforms are widely used for large-scale research and industrial applications. In addition, the MATLAB platform allows the flexible formulation of optimization models as well, although it currently has only limited capabilities for automatic differentiation and limited optimization solvers. More information on these and other modeling platforms can be found at http://www-fp.mcs.anl.gov/otc/Guide/SoftwareGuide.

Simulation platforms with optimization are often dedicated, application-specific modeling tools to which optimization solvers have been interfaced. These lead to very useful optimization studies, but because they were not originally designed for optimization models, they need to be used with some caution. In particular, most of these platforms do not provide exact derivatives to the optimization solver; often they are approximated through finite differences. In addition, the models themselves are constructed and calculated through numerical procedures, instead of through an open declarative language. Examples of these include widely used process simulators such as Aspen/Plus, PRO/II, and Hysys. Also note that more recent platforms such as Aspen Custom Modeler and gPROMS include declarative models and exact derivatives.

For optimization tools linked to procedural models, note that reliable and efficient automatic differentiation tools are available that link to models written, say, in FORTRAN and C, and calculate exact first (and often second) derivatives. Examples of these include ADIFOR, ADOL-C, GRESS, Odyssee, and PADRE. When used with care, these can be applied to existing procedural models and, when linked to modern NLP and MINLP algorithms, can lead to powerful optimization capabilities. More information on these and other automatic differentiation tools can be found at http://www-unix.mcs.anl.gov/autodiff/AD_Tools/.

For optimization problems that are derived from (ordinary or partial) differential equation models, a number of advanced optimization strategies can be applied. Most of these problems are posed as NLPs, although recent work has also extended these models to MINLPs and global optimization formulations. For the optimization of profiles in time and space, *indirect methods* can be applied based on the optimality conditions of the infinite-dimensional problem using, for instance, the calculus of variations. However, these methods become difficult to apply if inequality constraints and discrete decisions are part of the optimization problem. Instead, current methods are based on NLP and MINLP formulations and can be divided into two classes:

- *Simultaneous formulations* are based on converting the differential equation model to algebraic constraints via discretization (say, with a Runge-Kutta method) and solving a large-scale NLP or MINLP. This approach requires efficient large-scale optimization solvers but also leads to very flexible and efficient problem formulations, particularly for optimal control and state-constrained problems. It also allows the treatment of unstable dynamics. A review of these strategies can be found in Biegler et al. [*Chem. Engng. Sci.* **57**(4): 575 (2002)] and Betts [*Practical Methods for Optimal Control Using Nonlinear Programming,* SIAM, Philadelphia (2001)].
- *Sequential formulations* require the linkage of NLP or MINLP solvers to embedded ODE or PDE solvers. This leads to smaller optimization problems only in the decision (or control) variables. However, an important aspect to this formulation is the need to recover accurate gradient information from the differential equation solver. Here, methods based on the solution of *direct* and *adjoint sensitivity* equations have been derived and automated [see Cao et al., *SIAM J. Sci. Comp*. **24**(3): 1076 (2003) for a description of these sensitivity methods]. For the former, commercial tools such as Aspen Custom Modeler and gPROMS have been developed.

Finally, the availability of automatic differentiation and related sensitivity tools for differential equation models allows for considerable flexibility in the formulation of optimization models. In van Bloemen Waanders et al. (Sandia Technical Report SAND2002-3198, October 2002), a seven-level modeling hierarchy is proposed that matches optimization algorithms with models that range from completely open (fully declarative model) to fully closed (entirely procedural without sensitivities). At the lowest, fully procedural level, only derivative-free optimization methods are applied, while the highest, declarative level allows the application of an efficient large-scale solver that uses first and second derivatives. This report notes that, based on the modeling level, optimization solver performance can vary by several orders of magnitude.

INTRODUCTION

Statistics represents a body of knowledge which enables one to deal with quantitative data reflecting any degree of uncertainty. There are six basic aspects of applied statistics. These are:

1. Type of data
2. Random variables

3. Models
4. Parameters
5. Sample statistics
6. Characterization of chance occurrences

From these can be developed strategies and procedures for dealing with (1) estimation and (2) inferential statistics. The following has been directed more toward inferential statistics because of its broader utility.

Detailed illustrations and examples are used throughout to develop basic statistical methodology for dealing with a broad area of applications. However, in addition to this material, there are many specialized topics as well as some very subtle areas which have not been discussed. The references should be used for more detailed information. Section 8 discusses the use of statistics in statistical process control (SPC).

Type of Data In general, statistics deals with two types of data: counts and measurements. Counts represent the number of discrete outcomes, such as the number of defective parts in a shipment, the number of lost-time accidents, and so forth. Measurement data are treated as a continuum. For example, the tensile strength of a synthetic yarn theoretically could be measured to any degree of precision. A subtle aspect associated with count and measurement data is that some types of count data can be dealt with through the application of techniques which have been developed for measurement data alone. This ability is due to the fact that some simplified measurement statistics serve as an excellent approximation for the more tedious count statistics.

Random Variables Applied statistics deals with quantitative data. In tossing a fair coin the successive outcomes would tend to be different, with heads and tails occurring randomly over a period of time. Given a long strand of synthetic fiber, the tensile strength of successive samples would tend to vary significantly from sample to sample.

Counts and measurements are characterized as random variables, that is, observations which are susceptible to chance. Virtually all quantitative data are susceptible to chance in one way or another.

Models Part of the foundation of statistics consists of the mathematical models which characterize an experiment. The models themselves are mathematical ways of describing the probability, or relative likelihood, of observing specified values of random variables. For example, in tossing a coin once, a random variable x could be defined by assigning to x the value 1 for a head and 0 for a tail. Given a fair coin, the probability of observing a head on a toss would be a .5, and similarly for a tail. Therefore, the mathematical model governing this experiment can be written as

x	$P(x)$
0	.5
1	.5

where $P(x)$ stands for what is called a probability function. This term is reserved for count data, in that probabilities can be defined for particular outcomes.

The probability function that has been displayed is a very special case of the more general case, which is called the binomial probability distribution.

For measurement data which are considered continuous, the term *probability density* is used. For example, consider a spinner wheel which conceptually can be thought of as being marked off on the circumference infinitely precisely from 0 up to, but not including, 1. In spinning the wheel, the probability of the wheel's stopping at a specified marking point at any particular x value, where $0 \le x < 1$, is zero, for example, stopping at the value $x = \sqrt{.5}$. For the spinning wheel, the probability density function would be defined by $f(x) = 1$ for $0 \le x < 1$. Graphically, this is shown in Fig. 3-63. The relative-probability concept refers to the fact that density reflects the relative likelihood of occurrence; in this case, each number between 0 and 1 is equally likely. For measurement data, probability is defined by the area under the curve between specified limits. A density function always must have a total area of 1.

Example For the density of Fig. 3-63 the

$$P[0 \le x \le .4] = .4$$

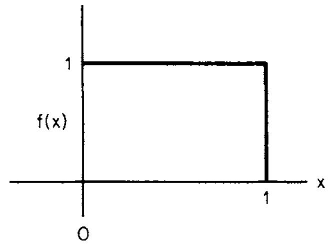

FIG. 3-63 Density function.

$$P[.2 \le x \le .9] = .7$$
$$P[.6 \le x < 1] = .4$$

and so forth. Since the probability associated with any particular point value is zero, it makes no difference whether the limit point is defined by a closed interval (≤ or ≥) or an open interval (< or >).

Many different types of models are used as the foundation for statistical analysis. These models are also referred to as **populations.**

Parameters As a way of characterizing probability functions and densities, certain types of quantities called parameters can be defined. For example, the center of gravity of the distribution is defined to be the population mean, which is designated as μ. For the coin toss μ = .5, which corresponds to the average value of x; i.e., for half of the time x will take on a value 0 and for the other half a value 1. The average would be .5. For the spinning wheel, the average value would also be .5.

Another parameter is called the **standard deviation,** which is designated as σ. The square of the standard deviation is used frequently and is called the popular **variance,** σ^2. Basically, the standard deviation is a quantity which measures the spread or dispersion of the distribution from its mean μ. If the spread is broad, then the standard deviation will be larger than if it were more constrained.

For specified probability and density functions, the respective means and variances are defined by the following:

Probability functions	Probability density functions
$E(x) = \mu = \sum_x x\,P(x)$	$E(x) = \mu = \int_x x\,f(x)\,dx$
$\mathrm{Var}(x) = \sigma^2 = \sum_x (x-\mu)^2\,P(x)$	$\mathrm{Var}(x) = \sigma^2 = \int_x (x-\mu)^2 f(x)\,dx$

where $E(x)$ is defined to be the expected or average value of x.

Sample Statistics Many types of sample statistics will be defined. Two very special types are the **sample mean,** designated as $\bar{x}$, and the sample standard deviation, designated as s. These are, by definition, random variables. Parameters like μ and σ are not random variables; they are fixed constants.

Example In an experiment, six random numbers (rounded to four decimal places) were observed from the uniform distribution $f(x) = 1$ for $0 \le x < 1$:

.1009
.3754
.0842
.9901
.1280
.6606

The sample mean corresponds to the arithmetic average of the observations, which will be designated as x_1 through x_6, where

$$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i \text{ with } n = 6, \quad \bar{x} = 0.3899$$

The sample standard deviation s is defined by the computation

$$s = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n-1}}$$

$$= \sqrt{\frac{n \sum x_i^2 - (\sum x_i)^2}{n(n-1)}} \qquad (3\text{-}118)$$

In effect, this represents the root of a statistical average of the squares. The divisor quantity $(n - 1)$ will be referred to as the degrees of freedom. The sample value of the standard deviation for the data given is .3686.

The value of $n - 1$ is used in the denominator because the deviations from the sample average must total zero, or

$$\Sigma(x_i - \bar{x}) = 0$$

Thus knowing $n - 1$ values of $x_i - \bar{x}$ permits calculation of the nth value of $x_i - \bar{x}$.

The sample mean and sample standard deviation are obtained by using Microsoft Excel with the commands AVERAGE(B2:B7) and STDEV(B2:B7) when the observations are in cells B2 to B7.

In effect, the standard deviation quantifies the relative magnitude of the deviation numbers, i.e., a special type of "average" of the distance of points from their center. In statistical theory, it turns out that the corresponding variance quantities s^2 have remarkable properties which make possible broad generalities for sample statistics and therefore also their counterparts, the standard deviations.

For the corresponding population, the parameter values are $\mu = .50$ and $\sigma = .2887$, which are obtained by calculating the integrals defined above with $f(x) = 1$ and $0 \le x \le 1$. If, instead of using individual observations only, averages of six were reported, then the corresponding population parameter values would be $\mu = .50$ and $\sigma_{\bar{x}} = \sigma/\sqrt{6} = .1179$. The corresponding variance for an average will be written occasionally as $\text{Var}(\bar{x}) = \text{var}(x)/n$. In effect, the variance of an average is inversely proportional to the sample size n, which reflects the fact that sample averages will tend to cluster about μ much more closely than individual observations. This is illustrated in greater detail under "Measurement Data and Sampling Densities."

Characterization of Chance Occurrences To deal with a broad area of statistical applications, it is necessary to characterize the way in which random variables will vary by chance alone. The basic foundation for this characteristic is laid through a density called the gaussian, or normal, distribution.

Determining the area under the normal curve is a very tedious procedure. However, by standardizing a random variable that is normally distributed, it is possible to relate all normally distributed random variables to one table. The standardization is defined by the identity $z = (x - \mu)/\sigma$, where z is called the unit normal. Further, it is possible to standardize the sampling distribution of averages $\bar{x}$ by the identity $z = (\bar{x} - \mu)/(\sigma/\sqrt{n})$.

A remarkable property of the normal distribution is that, almost regardless of the distribution of x, sample averages $\bar{x}$ will approach the gaussian distribution as n gets large. Even for relatively small values of n, of about 10, the approximation in most cases is quite close. For example, sample averages of size 10 from the uniform distribution will have essentially a gaussian distribution.

Also, in many applications involving count data, the normal distribution can be used as a close approximation. In particular, the approximation is quite close for the binomial distribution within certain guidelines.

The normal probability distribution function can be obtained in Microsoft Excel by using the NORMDIST function and supplying the desired mean and standard deviation. The cumulative value can also be determined. In MATLAB, the corresponding command is randn.

ENUMERATION DATA AND PROBABILITY DISTRIBUTIONS

Introduction Many types of statistical applications are characterized by enumeration data in the form of counts. Examples are the number of lost-time accidents in a plant, the number of defective items in a sample, and the number of items in a sample that fall within several specified categories.

The sampling distribution of count data can be characterized through probability distributions. In many cases, count data are appropriately interpreted through their corresponding distributions. However, in other situations analysis is greatly facilitated through distributions which have been developed for measurement data. Examples of each will be illustrated in the following subsections.

Binomial Probability Distribution

Nature Consider an experiment in which each outcome is classified into one of two categories, one of which will be defined as a success and the other as a failure. Given that the probability of success p is constant from trial to trial, then the probability of observing a specified number of successes x in n trials is defined by the binomial distribution. The sequence of outcomes is called a **Bernoulli process,**

Nomenclature

n = total number of trials
x = number of successes in n trials
p = probability of observing a success on any one trial
$\hat{p} = x/n$, the proportion of successes in n trials

Probability Law

$$P(x) = P\left(\frac{x}{n}\right) = \binom{n}{x} p^x (1-p)^{n-x} \qquad x = 0, 1, 2, \ldots, n$$

where $\displaystyle \binom{n}{x} = \frac{n!}{x!(n-x)!}$

Properties $E(x) = np \qquad \text{Var}(x) = np(1-p)$

$E(\hat{p}) = p \qquad \text{Var}(\hat{p}) = p(1-p)/n$

Geometric Probability Distribution

Nature Consider an experiment in which each outcome is classified into one of two categories, one of which will be defined as a success and the other as a failure. Given that the probability of success p is constant from trial to trial, then the probability of observing the first success on the xth trial is defined by the geometric distribution.

Nomenclature

p = probability of observing a success on any one trial
x = the number of trials to obtain the first success

Probability Law

$$P(x) = p(1-p)^{x-1} \qquad x = 1, 2, 3, \ldots$$

Properties

$$E(x) = 1/p \qquad \text{Var}(x) = (1-p)/p^2$$

Poisson Probability Distribution

Nature In monitoring a moving threadline, one criterion of quality would be the frequency of broken filaments. These can be identified as they occur through the threadline by a broken-filament detector mounted adjacent to the threadline. In this context, the random occurrences of broken filaments can be modeled by the Poisson distribution. This is called a Poisson process and corresponds to a probabilistic description of the frequency of defects or, in general, what are called arrivals at points on a continuous line or in time. Other examples include:

1. The number of cars (arrivals) that pass a point on a high-speed highway between 10:00 and 11:00 A.M. on Wednesdays
2. The number of customers arriving at a bank between 10:00 and 10:10 A.M.
3. The number of telephone calls received through a switchboard between 9:00 and 10:00 A.M.
4. The number of insurance claims that are filed each week
5. The number of spinning machines that break down during 1 day at a large plant.

Nomenclature

x = total number of arrivals in a total length L or total period T
a = average rate of arrivals for a unit length or unit time
$\lambda = aL$ = expected or average number of arrivals for the total length L
$\lambda = aT$ = expected or average number of arrivals for the total time T

Probability Law Given that a is constant for the total length L or period T, the probability of observing x arrivals in some period L or T

is given by

$$P(x) = \frac{\lambda^x}{x!} e^{-\lambda} \qquad x = 0, 1, 2, \ldots$$

Properties $E(x) = \lambda \qquad \text{Var}(x) = \lambda$

Example The number of broken filaments in a threadline has been averaging .015 per yard. What is the probability of observing exactly two broken filaments in the next 100 yd? In this example, $a = .015$/yd and $L = 100$ yd; therefore $\lambda = (.015)(100) = 1.5$:

$$P(x = 2) = \frac{(1.5)^2}{2!} e^{-1.5} = .2510$$

Example A commercial item is sold in a retail outlet as a unit product. In the past, sales have averaged 10 units per month with no seasonal variation. The retail outlet must order replacement items 2 months in advance. If the outlet starts the next 2-month period with 25 items on hand, what is the probability that it will stock out before the end of the second month?

Given $a = 10$/month, then $\lambda = 10 \times 2 = 20$ for the total period of 2 months:

$$P(x \geq 26) = \sum_{26}^{\infty} P(x) = 1 - \sum_{0}^{25} P(x)$$

$$\sum_{0}^{25} \frac{20^x}{x!} e^{-20} = e^{-20} \left[1 + \frac{20}{1} + \frac{20^2}{2!} + \cdots + \frac{20^{25}}{25!} \right]$$

$$= .887815$$

Therefore $P(x \geq 26) = .112185$ or roughly an 11 percent chance of a stockout.

Hypergeometric Probability Distribution

Nature In an experiment in which one samples from a relatively small group of items, each of which is classified in one of two categories, A or B, the hypergeometric distribution can be defined. One example is the probability of drawing two red and two black cards from a deck of cards. The hypergeometric distribution is the analog of the binomial distribution when successive trials are not independent, i.e., when the total group of items is not infinite. This happens when the drawn items are not replaced.

Nomenclature

N = total group size
n = sample group size
X = number of items in the total group with a specified attribute A
$N - X$ = number of items in the total group with the other attribute B
x = number of items in the sample with a specified attribute A
$n - x$ = number of items in the sample with the other attribute B

	Population	Sample
Category A	X	x
Category B	$N - X$	$n - x$
Total	N	n

Probability Law

$$P(x) = \binom{N-X}{n-x}\binom{X}{x} \Big/ \binom{N}{n}$$

$$E(x) = \frac{nX}{N}$$

$$\text{var}(x) = nP(1-P)\,\frac{N-n}{N-1}$$

Example What is the probability that an appointed special committee of 4 has no female members when the members are randomly selected from a candidate group of 10 males and 7 females?

$$P(x = 0) = \frac{\binom{10}{4}\binom{7}{0}}{\binom{17}{4}} = .0882$$

Example A bin contains 300 items, of which 240 are good and 60 are defective. In a sample of 6 what is the probability of selecting 4 good and 2 defective items by chance?

$$P(x) = \frac{\binom{240}{4}\binom{60}{2}}{\binom{300}{6}} = .2478$$

Multinomial Distribution

Nature For an experiment in which successive outcomes can be classified into two or more categories and the probabilities associated with the respective outcomes remain constant, then the experiment can be characterized through the multinomial distribution.

Nomenclature

n = total number of trials
k = total number of distinct categories
p_j = probability of observing category j on any one trial, $j = 1, 2, \ldots, k$
x_j = total number of occurrences in category j in n trials

Probability Law

$$P(x_1, x_2, \ldots, x_k) = \frac{n!}{x_1!x_2! \ldots x_k!} p_1^{x_1} p_2^{x_2} \cdots p_k^{x_k}$$

Example In tossing a die 12 times, what is the probability that each face value will occur exactly twice?

$$p(2, 2, 2, 2, 2, 2) = \frac{12!}{2!2!2!2!2!2!} \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 = .003438$$

To compute these probabilities in Microsoft Excel, put the value of x in cell B2, say, and use the functions

Binomial distribution: = BINOMDIST(B2, n,p,0)
Poisson distribution: = POISSON(B2,λ,0)
Hypergeometric distribution: = HYPGEOMDIST(B2,n,X,N)

To generate a table of values with these probability distributions, in Microsoft Excel use the following functions:

Bernoulli random values: = CRITBINOM(1,p,RAND())
Binomial random values: = CRITBINOM(n,p,RAND())

The factorial function is FACT(n) in Microsoft Excel and factorial(n) in MATLAB. Be sure that x is an integer.

MEASUREMENT DATA AND SAMPLING DENSITIES

Introduction The following example data are used throughout this subsection to illustrate concepts. Consider, for the purpose of illustration, that five synthetic-yarn samples have been selected randomly from a production line and tested for tensile strength on each of 20 production days. For this, assume that each group of five corresponds to a day, Monday through Friday, for a period of 4 weeks:

Monday 1	Tuesday 2	Wednesday 3	Thursday 4	Friday 5	Groups of 25 pooled
36.48	38.06	35.28	36.34	36.73	
35.33	31.86	36.58	36.25	37.17	
35.92	33.81	38.81	30.46	33.07	
32.28	30.30	33.31	37.37	34.27	
31.61	35.27	33.88	37.52	36.94	
$\bar{x}$ = 34.32	33.86	35.57	35.59	35.64	35.00
s = 2.22	3.01	2.22	2.92	1.85	2.40
6	7	8	9	10	
38.67	36.62	35.03	35.80	36.82	
32.08	33.05	36.22	33.16	36.49	
33.79	35.43	32.71	35.19	32.83	
32.85	36.63	32.52	32.91	32.43	
35.22	31.46	27.23	35.44	34.16	
$\bar{x}$ = 34.52	34.64	32.74	34.50	34.54	34.19
s = 2.60	2.30	3.46	1.36	2.03	2.35

11	12	13	14	15	
39.63	34.52	36.05	36.64	31.57	
34.38	37.39	35.36	31.18	36.21	
36.51	34.16	35.00	36.13	33.84	
30.00	35.76	33.61	37.51	35.01	
39.64	37.63	36.98	39.05	34.95	
$\bar{x}$ = 36.03	35.89	35.40	36.10	34.32	35.55
s = 4.04	1.59	1.25	2.96	1.75	2.42
Monday 16	**Tuesday 17**	**Wednesday 18**	**Thursday 19**	**Friday 20**	**Groups of 25 pooled**
37.68	35.97	33.71	35.61	36.65	
36.38	35.92	32.34	37.13	37.91	
38.43	36.51	33.29	31.37	42.18	
39.07	33.89	32.81	35.89	39.25	
33.06	36.01	37.13	36.33	33.32	
$\bar{x}$ = 36.92	35.66	33.86	35.27	37.86	35.91
s = 2.38	1.02	1.90	2.25	3.27	2.52

Pooled sample of 100: $\bar{x} = 35.16$ $s = 2.47$

Even if the process were at steady state, tensile strength, a key property would still reflect some variation. Steady state, or stable operation of any process, has associated with it a characteristic variation. Superimposed on this is the testing method, which is itself a process with its own characteristic variation. The observed variation is a composite of these two variations.

Assume that the table represents "typical" production-line performance. The numbers themselves have been generated on a computer and represent random observations from a population with $\mu = 35$ and a population standard deviation $\sigma = 2.45$. The sample values reflect the way in which tensile strength can vary by chance alone. In practice, a production supervisor unschooled in statistics but interested in high tensile performance would be despondent on the eighth day and exuberant on the twentieth day. If the supervisor were more concerned with uniformity, the lowest and highest points would have been on the eleventh and seventeenth days.

An objective of statistical analysis is to serve as a guide in decision making in the context of normal variation. In the case of the production supervisor, it is to make a decision, with a high probability of being correct, that something has in fact changed the operation.

Suppose that an engineering change has been made in the process and five new tensile samples have been tested with the results:

36.81	
38.34	$\bar{x} = 37.14$
34.87	$s = 1.85$
39.58	
36.12	

In this situation, management would inquire whether the product has been improved by increased tensile strength. To answer this question, in addition to a variety of analogous questions, it is necessary to have some type of scientific basis upon which to draw a conclusion.

A scientific basis for the evaluation and interpretation of data is contained in the accompanying table descriptions. These tables characterize the way in which sample values will vary by chance alone in the context of individual observations, averages, and variances.

Table number	Designated symbol	Variable	Sampling distribution of
3-5	z	$\dfrac{x-\mu}{\sigma}$	Observations*
3-5	z	$\dfrac{\bar{x}-\mu}{\sigma/\sqrt{n}}$	Averages
3-6	t	$\dfrac{\bar{x}-\mu}{s/\sqrt{n}}$	Averages when σ is unknown*
3-7	χ^2	(s^2/σ^2)(df)	Variances*
3-8	F	s_1^2/s_2^2	Ratio of two independent sample variances*

*When sampling from a gaussian distribution.

Normal Distribution of Observations Many types of data follow what is called the gaussian, or bell-shaped, curve; this is especially true of averages. Basically, the gaussian curve is a purely mathematical function which has very special properties. However, owing to some mathematically intractable aspects primary use of the function is restricted to tabulated values.

Basically, the tabled values represent area (proportions or probability) associated with a scaling variable designated by Z in Fig. 3-64. The normal curve is centered at 0, and for particular values of Z, designated as z, the tabulated numbers represent the corresponding area under the curve between 0 and z. For example, between 0 and 1 the area is .3413. (Get this number from Table 3-5. The value of A includes the area on both sides of zero. Thus we want $A/2$. For $z = 1$, $A = 0.6827$, $A/2 = 0.3413$. For $z = 2$, $A/2 = 0.4772$.) The area between 0 and 2 is .4772; therefore, the area between 1 and 2 is .4772 − .3413 = .1359.

Also, since the normal curve is symmetric, areas to the left can be determined in exactly the same way. For example, the area between −2 and +1 would include the area between −2 and 0, .4772 (the same as 0 to 2), plus the area between 0 and 1, .3413, or a total area of .8185.

Any types of observation which are applicable to the normal curve can be transformed to Z values by the relationship $z = (x - \mu)/\sigma$ and, conversely, Z values to x values by $x = \mu + \sigma z$, as shown in Fig. 3-64. For example, for tensile strength, with $\mu = 35$ and $\sigma = 2.45$, this would dictate $z = (x - 35)/2.45$ and $x = 35 + 2.45z$.

Example What proportion of tensile values will fall between 34 and 36?

$$z_1 = (34 - 35)/2.45 = -.41 \qquad z_2 = (36 - 35)/2.45 = .41$$

$$P[-.41 \le z \le .41] = .3182, \text{ or roughly 32 percent}$$

The value 0.3182 is interpolated from Table 3-4 using $z = \pm 0.40$, $A = 0.3108$, and $z = \pm 0.45$, $A = 0.3473$.

Example What midrange of tensile values will include 95 percent of the sample values? Since $P[-1.96 \le z \le 1.96] = .95$, the corresponding values of x are

$$x_1 = 35 - 1.96(2.45) = 30.2$$

$$x_2 = 35 + 1.96(2.45) = 39.8$$

or

$$P[30.2 \le x \le 39.8] = .95$$

Normal Distribution of Averages An examination of the tensile-strength data previously tabulated would show that the range (largest minus the smallest) of tensile strength within days averages 5.12. The average range in $\bar{x}$ values within each week is 2.37, while the range in the four weekly averages is 1.72. This reflects the fact that averages tend to be less variable in a predictable way. Given that the variance of x is var $(x) = \sigma^2$, then the variance of $\bar{x}$ based on n observations is var $(\bar{x}) = \sigma^2/n$.

For averages of n observations, the corresponding relationship for the Z-scale relationship is

$$z = (\bar{x} - \mu)/\sigma/\sqrt{n} \qquad \text{or} \qquad \bar{x} = \mu + \frac{\sigma}{\sqrt{n}} z$$

The Microsoft Excel function NORMDIST(X, μ, σ, 1) gives the probability that $x \le \mu$.

The command CONFIDENCE(α, σ, n) gives the confidence interval about the mean for a sample size n. To obtain 95 percent confidence limits, use $\alpha = .025$; $2\alpha = 1 - A$.

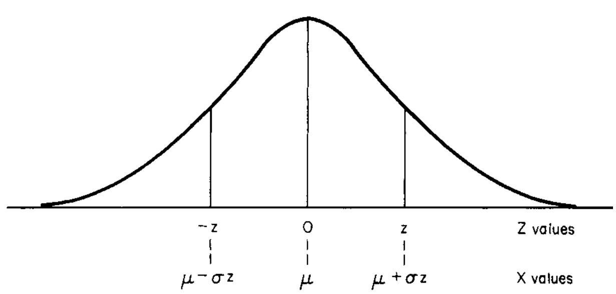

FIG. 3-64 Transformation of z values.

This table is obtained in Microsoft Excel with the function Y=NORMDIST(X, μ, σ, 0).
If $X > \mu$, A = 2 NORMDIST(X, μ, σ, 1) − 1. If $X < \mu$, A = 1 − 2 NORMDIST(X, μ, σ, 1)

Example What proportion of daily tensile averages will fall between 34 and 36? Using Table 3-5

$$z_1 = (34 - 35)/(2.45/\sqrt{5}) = -.91 \qquad z_2 = (36 - 35)/(2.45/\sqrt{5}) = .91$$

$$P[-.91 \le z \le .91] = .637, \text{ or roughly 64 percent}$$

Using Microsoft Excel, the more precise answer is

$$P[34 \le \bar{x} \le 36] = 2\ \text{NORMDIST}(36, 35, 2.45/\sqrt{5}, 1) - 1$$
$$= 1 - 2\ \text{NORMDIST}(34, 35, 2.45/\sqrt{5}, 1) = .6386$$

Example What midrange of daily tensile averages will include 95 percent of the sample values? Using Table 3-5

$$x_1 = 35 - 1.96(2.45/\sqrt{5}) = 32.85$$
$$x_2 = 35 + 1.96(2.45/\sqrt{5}) = 37.15$$
$$P[32.85 \le \bar{x} \le 37.15] = .95$$

or using Microsoft Excel,

$$35 \pm \text{CONFIDENCE}(.05, 2.45, 5) = 35 \pm 2.15$$

***t* Distribution of Averages** The normal curve relies on a knowledge of σ, or in special cases, when it is unknown, s can be used with the normal curve as an approximation when $n > 30$. For example, with $n > 30$ the intervals $\bar{x} \pm s$ and $\bar{x} \pm 2s$ will include roughly 68 and 95 percent of the sample values respectively when the distribution is normal.

In applications sample sizes are usually small and σ unknown. In these cases, the t distribution can be used where

$$t = (\bar{x} - \mu)/(s/\sqrt{n}) \qquad \text{or} \qquad \bar{x} = \mu + ts/\sqrt{n}$$

The t distribution is also symmetric and centered at zero. It is said to be robust in the sense that even when the individual observations x are not normally distributed, sample averages of x have distributions which tend toward normality as n gets large. Even for small n of 5 through 10, the approximation is usually relatively accurate. It is sometimes called the Student's t distribution.

In reference to the tensile-strength table, consider the summary statistics $\bar{x}$ and s by days. For each day, the t statistic could be computed. If this were repeated over an extensive simulation and the resultant t quantities plotted in a frequency distribution, they would match the corresponding distribution of t values summarized in Table 3-6.

Since the t distribution relies on the sample standard deviation s, the resultant distribution will differ according to the sample size n. To designate this difference, the respective distributions are classified according to what are called the degrees of freedom and abbreviated as df. In simple problems, the df are just the sample size minus 1. In more complicated applications the df can be different. In general, degrees of freedom are the number of quantities minus the number of constraints. For example, four numbers in a square which must have row and column sums equal to zero have only one df, i.e., four numbers minus three constraints (the fourth constraint is redundant). The Microsoft Excel function TDIST(X, df,1) gives the right-tail probability, and TDIST(X, df, 2) gives twice that. The probability that $t \le X$ is 1 − TDIST(X, df, 1) when $X \ge 0$ and TDIST(abs(X),df,1) when $X < 0$. The probability that $-X \le t \le +X$ is 1−TDIST(X, df, 2).

Example For a sample size $n = 5$, what values of t define a midarea of 90 percent? For 4 df the tabled value of t corresponding to a midarea of 90 percent is 2.132; i.e., $P[-2.132 \le t \le 2.132] = .90$.

Using Microsoft Excel, TINV(.1, 4) = 2.132.

Example For a sample size $n = 25$, what values of t define a midarea of 95 percent? For 24 df the tabled value of t corresponding to a midarea of 95 percent is 2.064; i.e., $P[-2.064 \le t \le 2.064] = .95$.

Example Also, 1 − TDIST(2.064, 24, 2) = .9500.

Using Microsoft Excel, TINV(.05, 24) = 2.064.

TABLE 3-6 Values of *t*

df	$t_{.40}$	$t_{.30}$	$t_{.20}$	$t_{.10}$	$t_{.05}$	$t_{.025}$	$t_{.01}$	$t_{.005}$
1	0.325	0.727	1.376	3.078	6.314	12.706	31.821	63.657

15	.258	.536	.866	1.341	1.753	2.131	2.602	2.947
16	.258	.535	.865	1.337	1.746	2.120	2.583	2.921
17	.257	.534	.863	1.333	1.740	2.110	2.567	2.898
18	.257	.534	.862	1.330	1.734	2.101	2.552	2.878
19	.257	.533	.861	1.328	1.729	2.093	2.539	2.861
20	.257	.533	.860	1.325	1.725	2.086	2.528	2.845
21	.257	.532	.859	1.323	1.721	2.080	2.518	2.831
22	.256	.532	.858	1.321	1.717	2.074	2.508	2.819
23	.256	.532	.858	1.319	1.714	2.069	2.500	2.807
24	.256	.531	.857	1.318	1.711	2.064	2.492	2.797
25	.256	.531	.856	1.316	1.708	2.060	2.485	2.787
26	.256	.531	.856	1.315	1.706	2.056	2.479	2.779
27	.256	.531	.855	1.314	1.703	2.052	2.473	2.771
28	.256	.530	.855	1.313	1.701	2.048	2.467	2.763
29	.256	.530	.854	1.311	1.699	2.045	2.462	2.756
30	.256	.530	.854	1.310	1.697	2.042	2.457	2.750
40	.255	.529	.851	1.303	1.684	2.021	2.423	2.704
60	.254	.527	.848	1.296	1.671	2.000	2.390	2.660
120	.254	.526	.845	1.289	1.658	1.980	2.358	2.617
∞	.253	.524	.842	1.282	1.645	1.960	2.326	2.576

Above values refer to a single tail outside the indicated limit of t. For example, for 95 percent of the area to be between $-t$ and $+t$ in a two-tailed t distribution, use the values for $t_{0.025}$ or 2.5 percent for each tail. This table is obtained in Mircrosoft Excel using the function TINV(α,df), where α is .05.

Example What is the sample value of t for the first day of tensile data?

$$\text{Sample } t = (34.32 - 35)/(2.22/\sqrt{5}) = -.68$$

Note that on the average 90 percent of all such sample values would be expected to fall within the interval ± 2.132.

***t* Distribution for the Difference in Two Sample Means with Equal Variances** The t distribution can be readily extended to the difference in two sample means when the respective populations have the same variance σ:

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{s_p\sqrt{1/n_1 + 1/n_2}} \tag{3-119}$$

where s_p^2 is a pooled variance defined by

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{(n_1 - 1) + (n_2 - 1)} \tag{3-120}$$

In this application, the t distribution has $(n_1 + n_2 - 2)$ df.

***t* Distribution for the Difference in Two Sample Means with Unequal Variances** When population variances are unequal, an approximate t quantity can be used:

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{\sqrt{a + b}}$$

with $$a = s_1^2/n_1 \qquad b = s_2^2/n_2$$

and $$\text{df} = \frac{(a + b)^2}{a^2/(n_1 - 1) + b^2/(n_2 - 1)}$$

Chi-Square Distribution For some industrial applications, product uniformity is of primary importance. The sample standard deviation s is most often used to characterize uniformity. In dealing with this problem, the chi-square distribution can be used where $\chi^2 = (s^2/\sigma^2)$ (df). The chi-square distribution is a family of distributions which are defined by the degrees of freedom associated with the sample variance. For most applications, df is equal to the sample size minus 1.

The probability distribution function is

$$p(y) = y_0 y^{df-2} \exp\left[\frac{-(df)^2}{2}\right]$$

where y_0 is chosen such that the integral of $p(y)$ over all y is one.

In terms of the tensile-strength table previously given, the respective chi-square sample values for the daily, weekly, and monthly figures could be computed. The corresponding df would be 4, 24, and 99 respectively. These numbers would represent sample values from the respective distributions which are summarized in Table 3-7.

In a manner similar to the use of the t distribution, chi square can be interpreted in a direct probabilistic sense corresponding to a midarea of $(1 - \alpha)$:

$$P[\chi_1^2 \le (s^2/\sigma^2)(\text{df}) \le \chi_2^2] = 1 - \alpha$$

where χ_1^2 corresponds to a lower-tail area of $\alpha/2$ and χ_2^2 an upper-tail area of $\alpha/2$.

The basic underlying assumption for the mathematical derivation of chi square is that a random sample was selected from a normal distribution with variance σ^2. When the population is not normal but skewed, chi-square probabilities could be substantially in error.

Example On the basis of a sample size $n = 5$, what midrange of values will include the sample ratio s/σ with a probability of 95 percent?

Use Table 3-7 for 4 df and read $\chi_1^2 = 0.484$ for a lower tail area of 0.05/2, 2.5 percent, and read $\chi_2^2 = 11.1$ for an upper tail area of 97.5 percent.

$$P[.484 \le (s^2/\sigma^2)(4) \le 11.1] = .95$$

or $$P[.35 \le s/\sigma \le 1.66] = .95$$

The Microsoft Excel functions CHIINV(.025, 4) and CHIINV(.975, 4) give the same values.

Example On the basis of a sample size $n = 25$, what midrange of values will include the sample ratio s/σ with a probability of 95 percent?

$$P[12.4 \le (s^2/\sigma^2)(24) \le 39.4] = .95$$

or $$P[.72 \le s/\sigma \le 1.28] = .95$$

This states that the sample standard deviation will be at least 72 percent and not more than 128 percent of the population variance 95 percent of the time. Conversely, 10 percent of the time the standard deviation will underestimate or overestimate the population standard deviation by the corresponding amount. Even for samples as large as 25, the relative reliability of a sample standard deviation is poor.

The chi-square distribution can be applied to other types of application which are of an entirely different nature. These include applications which are discussed under "Goodness-of-Fit Test" and "Two-Way Test for Independence of Count Data." In these applications, the mathematical formulation and context are entirely different, but they do result in the same table of values.

***F* Distribution** In reference to the tensile-strength table, the successive pairs of daily standard deviations could be ratioed and squared. These ratios of variance would represent a sample from a distribution called the F distribution or F ratio. In general, the F ratio is defined by the identity

$$F(\gamma_1, \gamma_2) = s_1^2/s_2^2$$

where γ_1 and γ_2 correspond to the respective df's for the sample variances. In statistical applications, it turns out that the primary area of interest is found when the ratios are greater than 1. For this reason, most tabled values are defined for an upper-tail area. However,

TABLE 3-7 Percentiles of the χ^2 Distribution

	Percent									
df	0.5	1	2.5	5	10	90	95	97.5	99	99.5
1	0.000039	0.00016	0.00098	0.0039	0.0158	2.71	3.84	5.02	6.63	7.88
2	.0100	.0201	.0506	.1026	.2107	4.61	5.99	7.38	9.21	10.60
3	.0717	.115	.216	.352	.584	6.25	7.81	9.35	11.34	12.84
4	.207	.297	.484	.711	1.064	7.78	9.49	11.14	13.28	14.86
5	.412	.554	.831	1.15	1.61	9.24	11.07	12.83	15.09	16.75
6	.676	.872	1.24	1.64	2.20	10.64	12.59	14.45	16.81	18.55

14	4.07	4.66	5.63	6.57	7.79	21.06	23.68	26.12	29.14	31.32
15	4.60	5.23	6.26	7.26	8.55	22.31	25.00	27.49	30.58	32.80
16	5.14	5.81	6.91	7.96	9.31	23.54	26.30	28.85	32.00	34.27
18	6.26	7.01	8.23	9.39	10.86	25.99	28.87	31.53	34.81	37.16
20	7.43	8.26	9.59	10.85	12.44	28.41	31.41	34.17	37.57	40.00
24	9.89	10.86	12.40	13.85	15.66	33.20	36.42	39.36	42.98	45.56
30	13.79	14.95	16.79	18.49	20.60	40.26	43.77	46.98	50.89	53.67
40	20.71	22.16	24.43	26.51	29.05	51.81	55.76	59.34	63.69	66.77
60	35.53	37.48	40.48	43.19	46.46	74.40	79.08	83.30	88.38	91.95
120	83.85	86.92	91.58	95.70	100.62	140.23	146.57	152.21	158.95	163.64

For large values of degrees of freedom the approximate formula

$$\chi_a^2 = n\left(1 - \frac{2}{9n} + z_a\sqrt{\frac{2}{9n}}\right)^3$$

where z_a is the normal deviate and n is the number of degrees of freedom, may be used. For example, $\chi_{.99}^2 = 60[1 - 0.00370 + 2.326(0.06086)]^3 = 60(1.1379)^3 = 88.4$ for the 99th percentile for 60 degrees of freedom. The Microsoft Excel function CHIDIST(X, df), where X is the table value, gives 1 – Percent. The function CHIINV (1– Percent, df) gives the table value.

defining F_2 to be that value corresponding to an upper-tail area of $\alpha/2$, then F_1 for a lower-tail area of $\alpha/2$ can be determined through the identity

$$F_1(\gamma_1, \gamma_2) = 1/F_2(\gamma_2, \gamma_1)$$

The F distribution, similar to the chi square, is sensitive to the basic assumption that sample values were selected randomly from a normal distribution. The Microsoft Excel function FDIST(X, df_1, df_2) gives the upper percent points of Table 3-8, where X is the tabular value. The function FINV(Percent, df_1, df_2) gives the table value.

Example For two sample variances with 4 df each, what limits will bracket their ratio with a midarea probability of 90 percent?

Use Table 3-8 with 4 df in the numerator and denominator and upper 5 percent points (to get both sides totaling 10 percent). The entry is 6.39. Thus:

$$P[1/6.39 \le s_1^2/s_2^2 \le 6.39] = .90$$

or

$$P[.40 \le s_1/s_2 \le 2.53] = .90$$

The Microsoft Excel function FINV(.05, 4, 4) gives 6.39, too.

Confidence Interval for a Mean For the daily sample tensile-strength data with 4 df it is known that $P[-2.132 \le t \le 2.132] = .90$. This states that 90 percent of all samples will have sample t values which fall within the specified limits. In fact, for the 20 daily samples exactly 16 do fall within the specified limits (note that the binomial with $n = 20$ and $p = .90$ would describe the likelihood of exactly none through 20 falling within the prescribed limits—the sample of 20 is only a sample).

Consider the new daily sample (with $n = 5$, $\bar{x} = 37.14$, and $s = 1.85$) which was observed after a process change. In this case, the same probability holds. However, in this instance the sample value of t cannot be computed, since the new μ, under the process change, is not known. Therefore $P[-2.132 \le (37.14 - \mu)/(1.85/\sqrt{5}) \le 2.132] = .90$. In effect, this identity limits the magnitude of possible values for μ. The magnitude of μ can be only large enough to retain the t quantity above -2.132 and small enough to retain the t quantity below $+2.132$. This can be found by rearranging the quantities within the bracket; i.e., $P[35.38 \le \mu \le 38.90] = .90$. This states that we are 90 percent sure that the interval from 35.38 to 38.90 includes the unknown parameter μ.

In general,

$$P\left[\bar{x} - t\frac{s}{\sqrt{n}} \le \mu \le \bar{x} + t\frac{s}{\sqrt{n}}\right] = 1 - \alpha$$

where t is defined for an upper-tail area of $\alpha/2$ with $(n - 1)$ df. In this application, the interval limits $(\bar{x} + t\, s/\sqrt{n})$ are random variables which will cover the unknown parameter μ with probability $(1 - \alpha)$. The converse, that we are $100(1 - \alpha)$ percent sure that the parameter value is within the interval, is not correct. This statement defines a probability for the parameter rather than the probability for the interval.

Example What values of t define the midarea of 95 percent for weekly samples of size 25, and what is the sample value of t for the second week?

$$P[-2.064 \le t \le 2.064] = .95$$

and

$$(34.19 - 35)/(2.35/\sqrt{25}) = 1.72.$$

Example For the composite sample of 100 tensile strengths, what is the 90 percent confidence interval for μ?

Use Table 3-6 for $t_{.05}$ with df $\approx \infty$.

$$P\left[35.16 - 1.645\frac{2.47}{\sqrt{100}} < \mu < 35.16 + 1.645\frac{2.47}{\sqrt{100}}\right] = .90$$

or

$$P[34.75 \le \mu \le 35.57] = .90$$

Confidence Interval for the Difference in Two Population Means The confidence interval for a mean can be extended to

TABLE 3-8 *F* Distribution

25	4.24	3.39	2.99	2.76	2.60	2.49	2.40	2.34	2.28	2.24	2.16	2.09	2.01	1.96	1.92	1.87	1.82	1.77	1.71
30	4.17	3.32	2.92	2.69	2.53	2.42	2.33	2.27	2.21	2.16	2.09	2.01	1.93	1.89	1.84	1.79	1.74	1.68	1.62
40	4.08	3.23	2.84	2.61	2.45	2.34	2.25	2.18	2.12	2.08	2.00	1.92	1.84	1.79	1.74	1.69	1.64	1.58	1.51
60	4.00	3.15	2.76	2.53	2.37	2.25	2.17	2.10	2.04	1.99	1.92	1.84	1.75	1.70	1.65	1.59	1.53	1.47	1.39
120	3.92	3.07	2.68	2.45	2.29	2.18	2.09	2.02	1.96	1.91	1.83	1.75	1.66	1.61	1.55	1.50	1.43	1.35	1.25
∞	3.84	3.00	2.60	2.37	2.21	2.10	2.01	1.94	1.88	1.83	1.75	1.67	1.57	1.52	1.46	1.39	1.32	1.22	1.00

Interpolation should be performed using reciprocals of the degrees of freedom.

include the difference between two population means. This interval is based on the assumption that the respective populations have the same variance σ^2:

$$(\bar{x}_1 - \bar{x}_2) - ts_p\sqrt{1/n_1 + 1/n_2} \le \mu_1 - \mu_2 \le (\bar{x}_1 - \bar{x}_2) + ts_p\sqrt{1/n_1 + 1/n_2}$$

Example Compute the 95 percent confidence interval based on the original 100-point sample and the subsequent 5-point sample:

$$s_p^2 = \frac{99(2.47)^2 + 4(1.85)^2}{103} = 5.997$$

or $$s_p = 2.45$$

With 103 df and $\alpha = .05$, $t = \pm 1.96$ using $t_{.025}$ in Table 3-6. Therefore

$$(35.16 - 37.14) \pm 1.96(2.45)\sqrt{1/100 + 1/5} = -1.98 \pm 2.20$$

or $$-4.18 \le (\mu_1 - \mu_2) \le .22$$

Note that if the respective samples had been based on 52 observations each rather than 100 and 5, the uncertainty factor would have been $\pm .94$ rather than the observed ± 2.20. The interval width tends to be minimum when $n_1 = n_2$.

Confidence Interval for a Variance The chi-square distribution can be used to derive a confidence interval for a population variance σ^2 when the parent population is normally distributed. For a $100(1 - \alpha)$ percent confidence interval

$$\frac{(\text{df})s^2}{\chi_2^2} \le \sigma^2 \le \frac{(\text{df})s^2}{\chi_1^2}$$

where χ_1^2 corresponds to a lower-tail area of $\alpha/2$ and χ_2^2 to an upper-tail area of $\alpha/2$.

Example For the first week of tensile-strength samples compute the 90 percent confidence interval for σ^2 (df = 24, corresponding to $n = 25$, using 5 percent and 95 percent in Table 3-7):

$$\frac{24(2.40)^2}{36.4} \le \sigma^2 \le \frac{24(2.40)^2}{13.8}$$

$$3.80 \le \sigma^2 \le 10.02$$

or $$1.95 \le \sigma \le 3.17$$

TESTS OF HYPOTHESIS

General Nature of Tests The general nature of tests can be illustrated with a simple example. In a court of law, when a defendant is charged with a crime, the judge instructs the jury initially to presume that the defendant is innocent of the crime. The jurors are then presented with evidence and counterargument as to the defendant's guilt or innocence. If the evidence suggests beyond a reasonable doubt that the defendant did, in fact, commit the crime, they have been instructed to find the defendant guilty; otherwise, not guilty. The burden of proof is on the prosecution.

Jury trials represent a form of decision making. In statistics, an analogous procedure for making decisions falls into an area of statistical inference called **hypothesis testing.**

Suppose that a company has been using a certain supplier of raw materials in one of its chemical processes. A new supplier approaches the company and states that its material, at the same cost, will increase the process yield. If the new supplier has a good reputation, the company might be willing to run a limited test. On the basis of the test results it would then make a decision to change suppliers or not. Good management would dictate that an improvement must be demonstrated

(beyond a reasonable doubt) for the new material. That is, the burden of proof is tied to the new material. In setting up a test of hypothesis for this application, the initial assumption would be defined as a null hypothesis and symbolized as H_0. The null hypothesis would state that yield for the new material is no greater than for the conventional material. The symbol μ_0 would be used to designate the known current level of yield for the standard material and μ for the unknown population yield for the new material. Thus, the null hypothesis can be symbolized as H_0: $\mu \le \mu_0$.

The alternative to H_0 is called the alternative hypothesis and is symbolized as H_1: $\mu > \mu_0$.

Given a series of tests with the new material, the average yield $\bar{x}$ would be compared with μ_0. If $\bar{x} < \mu_0$, the new supplier would be dismissed. If $\bar{x} > \mu_0$, the question would be: Is it sufficiently greater in the light of its corresponding reliability, i.e., beyond a reasonable doubt? If the confidence interval for μ included μ_0, the answer would be no, but if it did not include μ_0, the answer would be yes. In this simple application, the formal test of hypothesis would result in the same conclusion as that derived from the confidence interval. However, the utility of tests of hypothesis lies in their generality, whereas confidence intervals are restricted to a few special cases.

Test of Hypothesis for a Mean Procedure

Nomenclature

μ = mean of the population from which the sample has been drawn

σ = standard deviation of the population from which the sample has been drawn

μ_0 = base or reference level

H_0 = null hypothesis

H_1 = alternative hypothesis

α = significance level, usually set at .10, .05, or .01

t = tabled t value corresponding to the significance level α. For a two-tailed test, each corresponding tail would have an area of $\alpha/2$, and for a one-tailed test, one tail area would be equal to α. If σ^2 is known, then z would be used rather than the t.

$t = (\bar{x} - \mu_0)/(s/\sqrt{n})$ = sample value of the test statistic.

Assumptions

1. The n observations $x_1, x_2, \ldots, x_n$ have been selected randomly.
2. The population from which the observations were obtained is normally distributed with an unknown mean μ and standard deviation σ. In actual practice, this is a robust test, in the sense that in most types of problems it is not sensitive to the normality assumption when the sample size is 10 or greater.

Test of Hypothesis

1. Under the null hypothesis, it is assumed that the sample came from a population whose mean μ is equivalent to some base or reference designated by μ_0. This can take one of three forms:

Form 1	Form 2	Form 3
H_0: $\mu = \mu_0$	H_0: $\mu \le \mu_0$	H_0: $\mu \ge \mu_0$
H_1: $\mu \ne \mu_0$	H_1: $\mu > \mu_0$	H_1: $\mu < \mu_0$
Two-tailed test	Upper-tailed test	Lower-tailed test

2. If the null hypothesis is assumed to be true, say, in the case of a two-sided test, form 1, then the distribution of the test statistic t is known. Given a random sample, one can predict how far its sample value of t might be expected to deviate from zero (the midvalue of t) by chance alone. If the sample value of t does, in fact, deviate too far from zero, then this is defined to be sufficient evidence to refute the assumption of the null hypothesis. It is consequently rejected, and the converse or alternative hypothesis is accepted.
3. The rule for accepting H_0 is specified by selection of the α level as indicated in Fig. 3-65. For forms 2 and 3 the α area is defined to be in the upper or the lower tail respectively. The parameter α is the probability of rejecting the null hypothesis when it is actually true.
4. The decision rules for each of the three forms are defined as follows: If the sample t falls within the acceptance region, accept H_0 for lack of contrary evidence. If the sample t falls in the critical region, reject H_0 at a significance level of 100α percent.

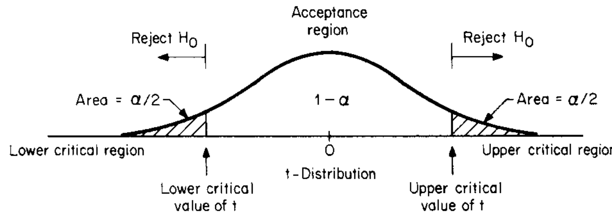

FIG. 3-65 Acceptance region for two-tailed test. For a one-tailed test, area = α on one side only.

Example

Application. In the past, the yield for a chemical process has been established at 89.6 percent with a standard deviation of 3.4 percent. A new supplier of raw materials will be used and tested for 7 days.

Procedure

1. The standard of reference is $\mu_0 = 89.6$ with a known $\sigma = 3.4$.
2. It is of interest to demonstrate whether an increase in yield is achieved with the new material; H_0 says it has not; therefore,

$$H_0: \mu \le 89.6 \qquad H_1: \mu > 89.6$$

3. Select $\alpha = .05$, and since σ is known (the new material would not affect the day-to-day variability in yield), the test statistic would be z with a corresponding critical value $cv(z) = 1.645$ (Table 3-6, df = ∞).
4. The decision rule:

$$\text{Accept } H_0 \text{ if sample } z < 1.645$$
$$\text{Reject } H_0 \text{ if sample } z > 1.645$$

5. A 7-day test was carried out, and daily yields averaged 91.6 percent with a sample standard deviation $s = 3.6$ (this is not needed for the test of hypothesis).
6. For the data sample $z = (91.6 - 89.6)/(3.4/\sqrt{7}) = 1.56$.
7. Since the sample $z < cv(z)$, accept the null hypothesis for lack of contrary evidence; i.e., an improvement has not been demonstrated beyond a reasonable doubt.

Example

Application. In the past, the break strength of a synthetic yarn has averaged 34.6 lb. The first-stage draw ratio of the spinning machines has been increased. Production management wants to determine whether the break strength has changed under the new condition.

Procedure

1. The standard of reference is $\mu_0 = 34.6$.
2. It is of interest to demonstrate whether a change has occurred; therefore,

$$H_0: \mu = 34.6 \qquad H_1: \mu \ne 34.6$$

3. Select $\alpha = .05$, and since with the change in draw ratio the uniformity might change, the sample standard deviation would be used, and therefore t would be the appropriate test statistic.
4. A sample of 21 ends was selected randomly and tested on an Instron with the results $\bar{x} = 35.55$ and $s = 2.041$.
5. For 20 df and a two-tailed α level of 5 percent, the critical values of $t_{.025}$ (two tailed) are given by ± 2.086 with a decision rule (Table 3-6, $t_{.025}$, df = 20):

$$\text{Accept } H_0 \text{ if } -2.086 < \text{sample } t < 2.086$$
$$\text{Reject } H_0 \text{ if sample } t < -2.086 \text{ or } > 2.086$$

6. For the data sample $t = (35.55 - 34.6)/(2.041/\sqrt{21}) = 2.133$.
7. Since 2.133 > 2.086, reject H_0 and accept H_1. It has been demonstrated that an improvement in break strength has been achieved.

Two-Population Test of Hypothesis for Means

Nature Two samples were selected from different locations in a plastic-film sheet and measured for thickness. The thickness of the respective samples was measured at 10 close but equally spaced points in each of the samples. It was of interest to compare the average thickness of the respective samples to detect whether they were significantly different. That is, was there a significant variation in thickness between locations?

From a modeling standpoint statisticians would define this problem as a two-population test of hypothesis. They would define the respective sample sheets as two populations from which 10 sample thickness determinations were measured for each.

In order to compare populations based on their respective samples, it is necessary to have some basis of comparison. This basis is predicated on the distribution of the t statistic. In effect, the t statistic characterizes

the way in which two sample means from two separate populations will tend to vary by chance alone when the population means and variances are equal. Consider the following:

Population 1		Population 2	
Normal	Sample 1	Normal	Sample 2
μ_1	n_1	μ_2	n_2
	$\bar{x}_1$		$\bar{x}_2$
σ_1^2	s_1^2	σ_2^2	s_2^2

Consider the hypothesis $\mu_1 = \mu_2$. If, in fact, the hypothesis is correct, i.e., $\mu_1 = \mu_2$ (under the condition $\sigma_1^2 = \sigma_2^2$), then the sampling distribution of $(\bar{x}_1 - \bar{x}_2)$ is predictable through the t distribution. The observed sample values then can be compared with the corresponding t distribution. If the sample values are reasonably close (as reflected through the α level), that is, $\bar{x}_1$ and $\bar{x}_2$ are not "too different" from each other on the basis of the t distribution, the null hypothesis would be accepted. Conversely, if they deviate from each other "too much" and the deviation is therefore not ascribable to chance, the conjecture would be questioned and the null hypothesis rejected.

Example

Application. Two samples were selected from different locations in a plastic-film sheet. The thickness of the respective samples was measured at 10 close but equally spaced points.

Procedure

1. Demonstrate whether the thicknesses of the respective sample locations are significantly different from each other; therefore,

$$H_0: \mu_1 = \mu_2 \qquad H_1: \mu_1 \neq \mu_2$$

2. Select $\alpha = .05$.
3. Summarize the statistics for the respective samples:

Sample 1		Sample 2	
1.473	1.367	1.474	1.417
1.484	1.276	1.501	1.448
1.484	1.485	1.485	1.469
1.425	1.462	1.435	1.474
1.448	1.439	1.348	1.452
$\bar{x}_1 = 1.434$	$s_1 = .0664$	$\bar{x}_2 = 1.450$	$s_2 = .0435$

4. As a first step, the assumption for the standard t test, that $\sigma_1^2 = \sigma_2^2$, can be tested through the F distribution. For this hypothesis, H_0: $\sigma_1^2 = \sigma_2^2$ would be tested against H_1: $\sigma_1^2 \neq \sigma_2^2$. Since this is a two-tailed test and conventionally only the upper tail for F is published, the procedure is to use the largest ratio and the corresponding ordered degrees of freedom. This achieves the same end result through one table. However, since the largest ratio is arbitrary, it is necessary to define the true α level as twice the value of the tabled value. Therefore, by using Table 3-8 with $\alpha = .05$ the corresponding critical value for $F(9,9) = 3.18$ would be for a true $\alpha = .10$. For the sample,

$$\text{Sample } F = (.0664/.0435)^2 = 2.33$$

Therefore, the ratio of sample variances is no larger than one might expect to observe when in fact $\sigma_1^2 = \sigma_2^2$. There is not sufficient evidence to reject the null hypothesis that $\sigma_1^2 = \sigma_2^2$.

5. For 18 df and a two-tailed α level of 5 percent the critical values of t are given by ± 2.101 (Table 3-6, $t_{0.025}$, $df = 18$).
6. The decision rule:

Accept H_0 if $-2.101 \le \text{sample } t \le 2.101$

Reject H_0 otherwise

7. For the sample the pooled variance estimate is given by Eq. (3-120).

$$s_p^2 = \frac{9(.0664)^2 + 9(.0435)^2}{9+9} = \frac{(.0664)^2 + (.0435)^2}{2} = .00315$$

or

$$s_p = .056$$

8. The sample statistic value of t is given by Eq. (3-119).

$$\text{Sample } t = \frac{1.434 - 1.450}{.056\sqrt{1/10 + 1/10}} = -.64$$

9. Since the sample value of t falls within the acceptance region, accept H_0 for lack of contrary evidence; i.e., there is insufficient evidence to demonstrate that thickness differs between the two selected locations.

Test of Hypothesis for Paired Observations

Nature In some types of applications, associated pairs of observations are defined. For example, (1) pairs of samples from two populations are treated in the same way, or (2) two types of measurements are made on the same unit. For applications of this type, it is not only more effective but necessary to define the random variable as the difference between the pairs of observations. The difference numbers can then be tested by the standard t distribution.

Examples of the two types of applications are as follows:

1. *Sample treatment*

a. Two types of metal specimens buried in the ground together in a variety of soil types to determine corrosion resistance

b. Wear-rate test with two different types of tractor tires mounted in pairs on n tractors for a defined period of time

2. *Same unit*

a. Blood-pressure measurements made on the same individual before and after the administration of a stimulus

b. Smoothness determinations on the same film samples at two different testing laboratories

Test of Hypothesis for Matched Pairs: Procedure

Nomenclature

d_i = sample difference between the ith pair of observations
s = sample standard deviation of differences
μ = population mean of differences
σ = population standard deviation of differences
μ_0 = base or reference level of comparison
H_0 = null hypothesis
H_1 = alternative hypothesis
α = significance level
t = tabled value with $(n-1)$ df
$t = (\bar{d} - \mu_0)/(s/\sqrt{n})$, the sample value of t

Assumptions

1. The n pairs of samples have been selected and assigned for testing in a random way.
2. The population of differences is normally distributed with a mean μ and variance σ^2. As in the previous application of the t distribution, this is a robust procedure, i.e., not sensitive to the normality assumption if the sample size is 10 or greater in most situations.

Test of Hypothesis

1. Under the null hypothesis, it is assumed that the sample came from a population whose mean μ is equivalent to some base or reference level designated by μ_0. For most applications of this type, the value of μ_0 is defined to be zero; that is, it is of interest generally to demonstrate a difference not equal to zero. The hypothesis can take one of three forms:

Form 1	Form 2	Form 3
H_0: $\mu = \mu_0$	H_0: $\mu \le \mu_0$	H_0: $\mu \ge \mu_0$
H_1: $\mu \neq \mu_0$	H_1: $\mu > \mu_0$	H_1: $\mu < \mu_0$
Two-tailed test	Upper-tailed test	Lower-tailed test

2. If the null hypothesis is assumed to be true, say, in the case of a lower-tailed test, form 3, then the distribution of the test statistic t is known under the null hypothesis that limits $\mu = \mu_0$. Given a random sample, one can predict how far its sample value of t might be expected to deviate from zero by chance alone when $\mu = \mu_0$. If the sample value of t is too small, as in the case of a negative value, then this would be defined as sufficient evidence to reject the null hypothesis.
3. Select α.
4. The critical values or value of t would be defined by the tabled value of t with $(n-1)$ df corresponding to a tail area of α. For a two-tailed test, each tail area would be $\alpha/2$, and for a one-tailed test there would be an upper-tail or a lower-tail area of α corresponding to forms 2 and 3 respectively.
5. The decision rule for each of the three forms would be to reject the null hypothesis if the sample value of t fell in that area of the t distribution defined by α, which is called the critical region.

Otherwise, the alternative hypothesis would be accepted for lack of contrary evidence.

Example

Application. Pairs of pipes have been buried in 11 different locations to determine corrosion on nonbituminous pipe coatings for underground use. One type includes a lead-coated steel pipe and the other a bare steel pipe.

Procedure

1. The standard of reference is taken as $\mu_0 = 0$, corresponding to no difference in the two types.
2. It is of interest to demonstrate whether either type of pipe has a greater corrosion resistance than the other. Therefore,

$$H_0: \mu = 0 \qquad H_1: \mu \neq 0$$

3. Select $\alpha = .05$. Therefore, with $n = 11$ the critical values of t with 10 df are defined by $t = \pm 2.228$ (Table 3.5, $t_{.025}$).
4. The decision rule:

$$\text{Accept } H_0 \text{ if } -2.228 \leq \text{sample } t \leq 2.228$$
$$\text{Reject } H_0 \text{ otherwise}$$

5. The sample of 11 pairs of corrosion determinations and their differences are as follows:

Soil type	Lead-coated steel pipe	Bare steel pipe	d = difference
A	27.3	41.4	−14.1
B	18.4	18.9	−0.5
C	11.9	21.7	−9.8
D	11.3	16.8	−5.5
E	14.8	9.0	5.8
F	20.8	19.3	1.5
G	17.9	32.1	−14.2
H	7.8	7.4	0.4
I	14.7	20.7	−6.0
J	19.0	34.4	−15.4
K	65.3	76.2	−10.9

6. The sample statistics, Eq. (3-118)

$$\bar{d} = -6.245 \qquad s^2 = \frac{11 \sum d^2 - (\sum d)^2}{11 \times 10} = 52.59$$

or

$$s = 7.25$$
$$\text{Sample } t = (-6.245 - 0)/(7.25/\sqrt{11})$$
$$= -2.86$$

7. Since the sample t of −2.86 < tabled t of −2.228, reject H_0 and accept H_1; that is, it has been demonstrated that, on the basis of the evidence, lead-coated steel pipe has a greater corrosion resistance than bare steel pipe.

Example

Application. A stimulus was tested for its effect on blood pressure. Ten men were selected randomly, and their blood pressure was measured before and after the stimulus was administered. It was of interest to determine whether the stimulus had caused a significant increase in the blood pressure.

Procedure

1. The standard of reference was taken as $\mu_0 \leq 0$, corresponding to no increase.
2. It was of interest to demonstrate an increase in blood pressure if in fact an increase did occur. Therefore,

$$H_0: \mu_0 \leq 0 \qquad H_1: \mu_0 > 0$$

3. Select $\alpha = .05$. Therefore, with $n = 10$ the critical value of t with 9 df is defined by $t = 1.833$ (Table 3-6, $t_{.05}$, one-sided).
4. The decision rule:

$$\text{Accept } H_0 \text{ if sample } t < 1.833$$
$$\text{Reject } H_0 \text{ if sample } t > 1.833$$

5. The sample of 10 pairs of blood pressure and their differences were as follows:

Individual	Before	After	d = difference
1	138	146	8
2	116	118	2
3	124	120	−4
4	128	136	8
5	155	174	19
6	129	133	4
7	130	129	−1
8	148	155	7
9	143	148	5
10	159	155	−4

6. The sample statistics:

$$\bar{d} = 4.4 \qquad s = 6.85$$
$$\text{Sample } t = (4.4 - 0)/(6.85/\sqrt{10}) = 2.03$$

7. Since the sample $t = 2.03 >$ critical $t = 1.833$, reject the null hypothesis. It has been demonstrated that the population of men from which the sample was drawn tend, as a whole, to have an increase in blood pressure after the stimulus has been given. The distribution of differences d seems to indicate that the degree of response varies by individuals.

Test of Hypothesis for a Proportion

Nature Some types of statistical applications deal with counts and proportions rather than measurements. Examples are (1) the proportion of workers in a plant who are out sick, (2) lost-time worker accidents per month, (3) defective items in a shipment lot, and (4) preference in consumer surveys.

The procedure for testing the significance of a sample proportion follows that for a sample mean. In this case, however, owing to the nature of the problem the appropriate test statistic is Z. This follows from the fact that the null hypothesis requires the specification of the goal or reference quantity p_0, and since the distribution is a binomial proportion, the associated variance is $[p_0(1 - p_0)]n$ under the null hypothesis. The primary requirement is that the sample size n satisfy normal approximation criteria for a binomial proportion, roughly $np > 5$ and $n(1 - p) > 5$.

Test of Hypothesis for a Proportion: Procedure

Nomenclature

p = mean proportion of the population from which the sample has been drawn

p_0 = base or reference proportion

$[p_0(1 - p_0)]/n$ = base or reference variance

$\hat{p} = x/n$ = sample proportion, where x refers to the number of observations out of n which have the specified attribute

H_0 = assumption or null hypothesis regarding the population proportion

H_1 = alternative hypothesis

α = significance level, usually set at .10, .05, or .01

z = tabled Z value corresponding to the significance level α. The sample sizes required for the z approximation according to the magnitude of p_0 are given in Table 3-6.

$z = (\hat{p} - p_0)/\sqrt{p_0(1 - p_0)/n}$, the sample value of the test statistic

Assumptions

1. The n observations have been selected randomly.
2. The sample size n is sufficiently large to meet the requirement for the Z approximation.

Test of Hypothesis

1. Under the null hypothesis, it is assumed that the sample came from a population with a proportion p_0 of items having the specified attribute. For example, in tossing a coin the population could be thought of as having an unbounded number of potential tosses. If it is assumed that the coin is fair, this would dictate $p_0 = 1/2$ for the proportional number of heads in the population. The null hypothesis can take one of three forms:

Form 1	Form 2	Form 3
$H_0: p = p_0$	$H_0: p \leq p_0$	$H_0: p \geq p_0$
$H_1: p \neq p_0$	$H_1: p > p_0$	$H_1: p < p_0$
Two-tailed test	Upper-tailed test	Lower-tailed test

2. If the null hypothesis is assumed to be true, then the sampling distribution of the test statistic Z is known. Given a random sample, it is possible to predict how far the sample proportion x/n might deviate from its assumed population proportion p_0 through the Z distribution. When the sample proportion deviates too far, as defined by the significance level α, this serves as the justification for rejecting the assumption, that is, rejecting the null hypothesis.

3. The decision rule is given by

Form 1: Accept H_0 if lower critical $z <$ sample $z <$ upper critical z
Reject H_0 otherwise

Form 2: Accept H_0 if sample $z <$ upper critical z
Reject H_0 otherwise

Form 3: Accept H_0 if lower critical $z <$ sample z
Reject H_0 otherwise

Example

Application. A company has received a very large shipment of rivets. One product specification required that no more than 2 percent of the rivets have diameters greater than 14.28 mm. Any rivet with a diameter greater than this would be classified as defective. A random sample of 600 was selected and tested with a go–no-go gauge. Of these, 16 rivets were found to be defective. Is this sufficient evidence to conclude that the shipment contains more than 2 percent defective rivets?

Procedure

1. The quality goal is $p \le .02$. It would be assumed initially that the shipment meets this standard; i.e., H_0: $p \le .02$.

2. The assumption in step 1 would first be tested by obtaining a random sample. Under the assumption that $p \le .02$, the distribution for a sample proportion would be defined by the z distribution. This distribution would define an upper bound corresponding to the upper critical value for the sample proportion. It would be unlikely that the sample proportion would rise above that value if, in fact, $p \le .02$. If the observed sample proportion exceeds that limit, corresponding to what would be a very unlikely chance outcome, this would lead one to question the assumption that $p \le .02$. That is, one would conclude that the null hypothesis is false. To test, set

$$H_0: p \le .02 \qquad H_1: p > .02$$

3. Select $\alpha = .05$.

4. With $\alpha = .05$, the upper critical value of Z = 1.645 (Table 3-6, $t_{.05}$, df = ∞, one-sided).

5. The decision rule:

$$\text{Accept } H_0 \text{ if sample } z < 1.645$$
$$\text{Reject } H_0 \text{ if sample } z > 1.645$$

6. The sample z is given by

$$\text{Sample } z = \frac{(16/600) - .02}{\sqrt{(.02)(.98)/600}} = 1.17$$

7. Since the sample $z < 1.645$, accept H_0 for lack of contrary evidence; there is not sufficient evidence to demonstrate that the defect proportion in the shipment is greater than 2 percent.

Test of Hypothesis for Two Proportions

Nature In some types of engineering and management-science problems, we may be concerned with a random variable which represents a proportion, for example, the proportional number of defective items per day. The method described previously relates to a single proportion. In this subsection two proportions will be considered.

A certain change in a manufacturing procedure for producing component parts is being considered. Samples are taken by using both the existing and the new procedures in order to determine whether the new procedure results in an improvement. In this application, it is of interest to demonstrate statistically whether the population proportion p_2 for the new procedure is less than the population proportion p_1 for the old procedure on the basis of a sample of data.

Test of Hypothesis for Two Proportions: Procedure

Nomenclature

p_1 = population 1 proportion
p_2 = population 2 proportion
n_1 = sample size from population 1
n_2 = sample size from population 2
x_1 = number of observations out of n_1 that have the designated attribute
x_2 = number of observations out of n_2 that have the designated attribute
$\hat{p}_1 = x_1/n_1$, the sample proportion from population 1
$\hat{p}_2 = x_2/n_2$, the sample proportion from population 2
α = significance level
H_0 = null hypothesis
H_1 = alternative hypothesis
z = tabled Z value corresponding to the stated significance level α

$$z = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\hat{p}_1(1-\hat{p}_1)/n_1 + \hat{p}_2(1-\hat{p}_2)/n_2}}, \text{ the sample value of Z}$$

Assumptions

1. The respective two samples of n_1 and n_2 observations have been selected randomly.

2. The sample sizes n_1 and n_2 are sufficiently large to meet the requirement for the Z approximation; i.e., $x_1 > 5$, $x_2 > 5$.

Test of Hypothesis

1. Under the null hypothesis, it is assumed that the respective two samples have come from populations with equal proportions $p_1 = p_2$. Under this hypothesis, the sampling distribution of the corresponding Z statistic is known. On the basis of the observed data, if the resultant sample value of Z represents an unusual outcome, that is, if it falls within the critical region, this would cast doubt on the assumption of equal proportions. Therefore, it will have been demonstrated statistically that the population proportions are in fact not equal. The various hypotheses can be stated:

Form 1	Form 2	Form 3
H_0: $p_1 = p_2$	H_0: $p_1 \le p_2$	H_0: $p_1 \ge p_2$
H_1: $p_1 \ne p_2$	H_1: $p_1 > p_2$	H_1: $p_1 < p_2$
Two-tailed test	Upper-tailed test	Lower-tailed test

2. The decision rule for form 1 is given by

Accept H_0 if lower critical $z <$ sample $z <$ upper critical z
Reject H_0 otherwise

Example

Application. A change was made in a manufacturing procedure for component parts. Samples were taken during the last week of operations with the old procedure and during the first week of operations with the new procedure. Determine whether the proportional numbers of defects for the respective populations differ on the basis of the sample information.

Procedure

1. The hypotheses are

$$H_0: p_1 = p_2 \qquad H_1: p_1 \ne p_2$$

2. Select $\alpha = .05$. Therefore, the critical values of z are ± 1.96 (Table 3-5, $A = 0.9500$).

3. For the samples, 75 out of 1720 parts from the previous procedure and 80 out of 2780 parts under the new procedure were found to be defective; therefore,

$$\hat{p}_1 = 75/1720 = .0436 \qquad \hat{p}_2 = 80/2780 = .0288$$

4. The decision rule:

Accept H_0 if $-1.96 \le$ sample $z \le 1.96$
Reject H_0 otherwise

5. The sample statistic:

$$\text{Sample } z = \frac{.0436 - .0288}{\sqrt{(.0436)(.9564)/1720 + (.0288)(.9712)/2780}} = 2.53$$

6. Since the sample z of 2.53 > tabled z of 1.96, reject H_0 and conclude that the new procedure has resulted in a reduced defect rate.

Goodness-of-Fit Test

Nature A standard die has six sides numbered from 1 to 6. If one were really interested in determining whether a particular die was well balanced, one would have to carry out an experiment. To do this, it might be decided to count the frequencies of outcomes, 1 through 6, in tossing the die N times. On the assumption that the die is perfectly balanced,

one would expect to observe $N/6$ occurrences each for 1, 2, 3, 4, 5, and 6. However, chance dictates that exactly $N/6$ occurrences each will not be observed. For example, given a perfectly balanced die, the probability is only 1 chance in 65 that one will observe 1 outcome each, for 1 through 6, in tossing the die 6 times. Therefore, an outcome different from 1 occurrence each can be expected. Conversely, an outcome of six 3s would seem to be too unusual to have occurred by chance alone.

Some industrial applications involve the concept outlined here. The basic idea is to test whether or not a group of observations follows a preconceived distribution. In the case cited, the distribution is uniform; i.e., each face value should *tend* to occur with the same frequency.

Goodness-of-Fit Test: Procedure

Nomenclature Each experimental observation can be classified into one of r possible categories or cells.

r = total number of cells
O_j = number of observations occurring in cell j
E_j = expected number of observations for cell j based on the preconceived distribution
N = total number of observations
f = degrees of freedom for the test. In general, this will be equal to $(r - 1)$ minus the number of statistical quantities on which the E_j's are based (see the examples which follow for details).

Assumptions

1. The observations represent a sample selected randomly from a population which has been specified.
2. The number of expectation counts E_j within each category should be roughly 5 or more. If an E_j count is significantly less than 5, that cell should be pooled with an adjacent cell.

Computation for $\mathbf{E_j}$ On the basis of the specified population, the probability of observing a count in cell j is defined by p_j. For a sample of size N, corresponding to N total counts, the expected frequency is given by $E_j = Np_j$.

Test Statistics: Chi Square

$$\chi^2 = \sum_{j=1}^{r} \frac{(O_j - E_j)^2}{E_j} \qquad \text{with } f \text{ df}$$

Test of Hypothesis

1. H_0: The sample came from the specified theoretical distribution
 H_1: The sample did not come from the specified theoretical distribution
2. For a stated level of α,
 Reject H_0 if sample $\chi^2 >$ tabled χ^2
 Accept H_0 if sample $\chi^2 <$ tabled χ^2

Example

Application A production-line product is rejected if one of its characteristics does not fall within specified limits. The standard goal is that no more than 2 percent of the production should be rejected.

Computation

1. Of 950 units produced during the day, 28 units were rejected.
2. The hypotheses:

 H_0: the process is in control
 H_1: the process is not in control

3. Assume that $\alpha = .05$; therefore, the critical value of $\chi^2(1) = 3.84$ (Table 3-7, 95 percent, df = 1). One degree of freedom is defined since $(r - 1) = 1$, and no statistical quantities have been computed for the data.
4. The decision rule:

 Reject H_0 if sample $\chi^2 > 3.84$
 Accept H_0 otherwise

5. Since it is assumed that $p = .02$, this would dictate that in a sample of 950 there would be on the average (.02)(950) = 19 defective items and 931 acceptable items:

Category	Observed O_j	Expectation $E_j = 950p_j$
Acceptable	922	931
Not acceptable	28	19
Total	950	950

$$\text{Sample } \chi^2 = \frac{(922 - 931)^2}{931} + \frac{(28 - 19)^2}{19} = 4.35 \text{ with critical } \chi^2 = 3.84$$

6. Conclusion. Since the sample value exceeds the critical value, it would be concluded that the process is not in control.

Example

Application A frequency count of workers was tabulated according to the number of defective items that they produced. An unresolved question is whether the observed distribution is a Poisson distribution. That is, do observed and expected frequencies agree within chance variation?

Computation

1. The hypotheses:
 H_0: there are no significant differences, in number of defective units, between workers
 H_1: there are significant differences
2. Assume that $\alpha = .05$.
3. Test statistic:

No. of defective units	O_j		E_j	
0	3	10	2.06	8.70 pool
1	7		6.64	
2	9		10.73	
3	12		11.55	
4	9		9.33	
5	6		6.03	
6	3	6	3.24	5.66 pool
7	2		1.50	
8	0		.60	
9	1		.22	
≥10	0		.10	
Sum	52		52	

The expectation numbers E_j were computed as follows: For the Poisson distribution, $\lambda = E(x)$; therefore, an estimate of λ is the average number of defective units per worker, i.e., $\lambda = (1/52)(0 \times 3 + 1 \times 7 + \cdots + 9 \times 1) = 3.23$. Given this approximation, the probability of no defective units for a worker would be $(3.23)^0/0!)e^{-3.23} = .0396$. For the 52 workers, the number of workers producing no defective units would have an expectation $E = 52(0.0396) = 2.06$, and so forth.

The sample chi-square value is computed from

$$\chi^2 = \frac{(10 - 8.70)^2}{8.70} + \frac{(9 - 10.73)^2}{10.73} + \cdots + \frac{(6 - 5.66)^2}{5.66} = .522$$

4. The critical value of χ^2 would be based on four degrees of freedom. This corresponds to $(r - 1) - 1$, since one statistical quantity λ was computed from the sample and used to derive the expectation numbers.
5. The critical value of $\chi^2(4) = 9.49$ (Table 3-7) with $\alpha = .05$; therefore, accept H_0.

Two-Way Test for Independence for Count Data

Nature When individuals or items are observed and classified according to two different criteria, the resultant counts can be statistically analyzed. For example, a market survey may examine whether a new product is preferred and if it is preferred due to a particular characteristic.

Count data, based on a random selection of individuals or items which are classified according to two different criteria, can be statistically analyzed through the χ^2 distribution. The purpose of this analysis is to determine whether the respective criteria are dependent. That is, is the product preferred because of a particular characteristic?

Two-Way Test for Independence for Count Data: Procedure

Nomenclature

1. Each observation is classified according to two categories:
 a. The first one into 2, 3, . . . , or r categories
 b. The second one into 2, 3, . . . , or c categories
2. O_{ij} = number of observations (observed counts) in cell (i, j) with

$$i = 1, 2, \ldots, r$$
$$j = 1, 2, \ldots, c$$

3. N = total number of observations
4. E_{ij} = computed number for cell (i,j) which is an expectation based on the assumption that the two characteristics are independent
5. R_i = subtotal of counts in row i
6. C_j = subtotal of counts in column j
7. α = significance level
8. H_0 = null hypothesis
9. H_1 = alternative hypothesis
10. χ^2 = critical value of χ^2 corresponding to the significance level α and $(r-1)(c-1)$ df
11. Sample $\chi^2 = \sum_{i,j}^{c,r} \frac{(O_{ij}-E_{ij})^2}{E_{ij}}$

Assumptions
1. The observations represent a sample selected randomly from a large total population.
2. The number of expectation counts E_{ij} within each cell should be approximately 2 or more for arrays 3×3 or larger. If any cell contains a number smaller than 2, appropriate rows or columns should be combined to increase the magnitude of the expectation count. For arrays 2×2, approximately 4 or more are required. If the number is less than 4, the exact Fisher test should be used.

Test of Hypothesis Under the null hypothesis, the classification criteria are assumed to be independent, i.e.,

H_0: the criteria are independent

H_1: the criteria are not independent

For the stated level of α,

Reject H_0 if sample χ^2 > tabled χ^2
Accept H_0 otherwise

***Computation for* E_{ij}** Compute E_{ij} across rows or down columns by using either of the following identities:

$$E_{ij} = C_j\left(\frac{R_i}{N}\right) \text{ across rows}$$

$$E_{ij} = R_i\left(\frac{C_j}{N}\right) \text{ down columns}$$

Sample χ^2 Value

$$\chi^2 = \sum_{i,j} \frac{(O_{ij}-E_{ij})^2}{E_{ij}}$$

In the special case of $r = 2$ and $c = 2$, a more accurate and simplified formula which does not require the direct computation of E_{ij} can be used:

$$\chi^2 = \frac{[|O_{11}O_{22} - O_{12}O_{21}| - \tfrac{1}{2}N]^2 N}{R_1R_2C_1C_2}$$

Example

Application A market research study was carried out to relate the subjective "feel" of a consumer product to consumer preference. In other words, is the consumer's preference for the product associated with the feel of the product, or is the preference independent of the product feel?

Procedure

1. It was of interest to demonstrate whether an association exists between feel and preference; therefore, assume

H_0: feel and preference are independent
H_1: they are not independent

2. A sample of 200 people was asked to classify the product according to two criteria:
a. Liking for this product
b. Liking for the feel of the product

		Like feel		
		Yes	No	R_i
Like product	Yes	114	13	= 127
	No	55	18	= 73
	C_j	169	31	200

3. Select $\alpha = .05$; therefore, with $(r-1)(c-1) = 1$ df, the critical value of χ^2 is 3.84 (Table 3-7, 95 percent).
4. The decision rule:

Accept H_0 if sample $\chi^2 < 3.84$
Reject H_0 otherwise

5. The sample value of χ^2 by using the special formula is

$$\text{Sample } \chi^2 = \frac{[|114 \times 18 - 13 \times 55| - 100]^2 200}{(169)(31)(127)(73)} = 6.30$$

6. Since the sample χ^2 of 6.30 > tabled χ^2 of 3.84, reject H_0 and accept H_1. The relative proportionality of $E_{11} = 169(127/200) = 107.3$ to the observed 114 compared with $E_{22} = 31(73/200) = 11.3$ to the observed 18 suggests that when the consumer likes the feel, the consumer tends to like the product, and conversely for not liking the feel. The proportions 169/200 = 84.5 percent and 127/200 = 63.5 percent suggest further that there are other attributes of the product which tend to nullify the beneficial feel of the product.

LEAST SQUARES

When experimental data is to be fit with a mathematical model, it is necessary to allow for the fact that the data has errors. The engineer is interested in finding the parameters in the model as well as the uncertainty in their determination. In the simplest case, the model is a linear equation with only two parameters, and they are found by a least-squares minimization of the errors in fitting the data. Multiple regression is just linear least squares applied with more terms. Nonlinear regression allows the parameters of the model to enter in a nonlinear fashion. See Press et al. (1986); for a description of maximum likelihood as it applies to both linear and nonlinear least squares.

In a least squares parameter estimation, it is desired to find parameters that minimize the sum of squares of the deviation between the experimental data and the theoretical equation.

$$\chi^2 = \sum_{i=1}^{N} [y_i - y(x_i; a_1, a_2, \ldots, a_M)]^2$$

where y_i is the ith experimental data point for the value x_i, $y(x_i; a_1, a_2, \ldots, a_M)$ is the theoretical equation at x_i, and the parameters $\{a_1, a_2, \ldots, a_M\}$ are to be determined to minimize χ^2. This will also minimize the variance of the curve fit

$$\sigma^2 = \sum_{i=1}^{N} \frac{[y_i - y(x_i; a_1, a_2, \ldots, a_M)]^2}{N}$$

Linear Least Squares When the model is a straight line, one is minimizing

$$\chi^2 = \sum_{i=1}^{N} (y_i - a - bx_i)^2$$

The linear correlation coefficient r is defined by

$$r = \frac{\sum_{i=1}^{N} (x_i - \overline{x})(y_i - \overline{y})}{\sqrt{\sum_{i=1}^{N}(x_i - \overline{x})^2}\sqrt{\sum_{i=1}^{N}(y_i - \overline{y})^2}}$$

and

$$\chi^2 = (1 - r^2) \sum_{i=1}^{N} (y_i - \overline{y})^2$$

where $\overline{y}$ is the average of the y_i values. Values of r near 1 indicate a positive correlation; r near –1 means a negative correlation, and r near 0 means no correlation. These parameters are easily found by using standard programs, such as Microsoft Excel.

Example

Application. Brenner (*Magnetic Method for Measuring the Thickness of Non-magnetic Coatings on Iron and Steel,* National Bureau of Standards, RP1081, March 1938) suggests an alternative way of measuring the thickness of nonmagnetic coatings of galvanized zinc on iron and steel. This procedure is based on a nondestructive magnetic method as a substitute for the standard

destructive stripping method. A random sample of 11 pieces was selected and measured by both methods.

Nomenclature. The calibration between the magnetic and the stripping methods can be determined through the model

$$y = a + bx + \varepsilon$$

where x = strip-method determination
y = magnetic-method determination

Sample data

Thickness, 10^{-5} in

Stripping method, x	Magnetic method, y
104	85
114	115
116	105
129	127
132	120
139	121
174	155
312	250
338	310
465	443
720	630

This example is solved by using Microsoft Excel. Put the data into columns A and B as shown, using rows 1 through 11. Then the commands

SLOPE(B1:B11, A1:A11), INTERCEPT(B1:B11, A1:A11),
RSQ(B1:B11, A1:A11)

give the slope b, the intercept a, and the value of r^2. Here they are 3.20, 0.884, and 0.9928, respectively, so that r = 0.9964. By choosing Insert/Chart and Scatter Plot, the data are plotted. Once that is done, place the cursor on a data point and right-click; choose Format trendline with options selected to display the equation and r^2, and you get Fig. 3-66. On the Macintosh, use CTRL-click.

Polynomial Regression In polynomial regression, one expands the function in a polynomial in x.

$$y(x) = \sum_{j=1}^{M} = a_j x^{j-1}$$

Example

Application. Merriman ("The Method of Least Squares Applied to a Hydraulic Problem," *J. Franklin Inst.*, 233–241, October 1877) reported on a study of stream velocity as a function of relative depth of the stream.

Sample data

Depth*	Velocity, y, ft/s
0	3.1950
.1	3.2299
.2	3.2532
.3	3.2611
.4	3.2516
.5	3.2282
.6	3.1807
.7	3.1266
.8	3.0594
.9	2.9759

*As a fraction of total depth.

The model is taken as a quadratic function of position:

$$\text{Velocity} = a + bx + cx^2$$

The parameters are easily determined by using computer software. In Microsoft Excel, the data are put into columns A and B and the graph is created as for a linear curve fit. This time, though, when adding the trendline, choose the polynomial icon and use 2 (which gives powers up to and including x^2). The result is

$$\text{Velocity} = 3.195 + 0.4425x - 0.7653x^2$$

The value of r^2 is .9993.

Multiple Regression In multiple regression, any set of functions can be used, not just polynomials, such as

$$y(x) = \sum_{j=1}^{M} a_j f_j(x)$$

where the set of functions $\{f_j(x)\}$ is known and specified. Note that the unknown parameters $\{a_j\}$ enter the equation linearly. In this case, the spreadsheet can be expanded to have a column for x and then successive columns for $f_j(x)$. In Microsoft Excel, you choose Regression under Tools/Data Analysis, and complete the form. In addition to the actual correlation, you get the expected variance of the unknowns, which allows you to assess how accurately they were determined. In the example above, by creating a column for x and x^2, one obtains an intercept of 3.195 with a standard error of .0039, b = .4416 with a standard error of .018, and c = −.7645 with a standard error of .018.

Nonlinear Least Squares There are no analytic methods for determining the most appropriate model for a particular set of data.

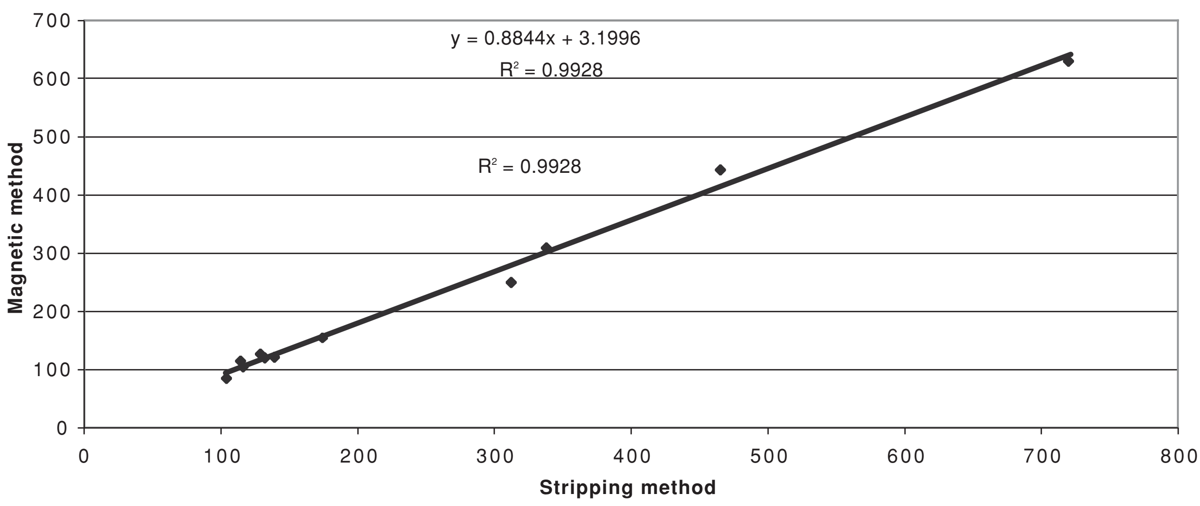

FIG. 3-66 Plot of data and correlating line.

In many cases, however, the engineer has some basis for a model. If the parameters occur in a nonlinear fashion, then the analysis becomes more difficult. For example, in relating the temperature to the elapsed time of a fluid cooling in the atmosphere, a model that has an asymptotic property would be the appropriate model (temp = $a + b$ exp($-c$ time), where a represents the asymptotic temperature corresponding to $t \rightarrow \infty$. In this case, the parameter c appears nonlinearly. The usual practice is to concentrate on model development and computation rather than on statistical aspects. In general, nonlinear regression should be applied only to problems in which there is a well-defined, clear association between the two variables; therefore, a test of hypothesis on the significance of the fit would be somewhat ludicrous. In addition, the generalization of the theory for the associate confidence intervals for nonlinear coefficients is not well developed.

Example

Application. Data were collected on the cooling of water in the atmosphere as a function of time.

Sample data

Time x	Temperature y
0	92.0
1	85.5
2	79.5
3	74.5
5	67.0
7	60.5
10	53.5
15	45.0
20	39.5

Model. MATLAB can be used to find the best fit of the data to the formula $y = a + be^{cx}$: $a = 33.54$, $b = 57.89$, $c = 0.11$. The value of χ^2 is 1.83. Using an alternative form, $y = a + b/(c + x)$, gives $a = 9.872$, $b = 925.7$, $c = 11.27$, and $\chi = 0.19$. Since this model had a smaller value of χ^2 it might be the chosen one, but it is only a fit of the specified data and may not be generalized beyond that. Both forms give equivalent plots.

ERROR ANALYSIS OF EXPERIMENTS

Consider the problem of assessing the accuracy of a series of measurements. If measurements are for independent, identically distributed observations, then the errors are independent and uncorrelated. Then $\bar{y}$, the experimentally determined mean, varies about $E(y)$, the true mean, with variance σ^2/n, where n is the number of observations in $\bar{y}$. Thus, if one measures something several times today, and each day, and the measurements have the same distribution, then the variance of the means decreases with the number of samples in each day's measurement, n. Of course, other factors (weather, weekends) may make the observations on different days *not* distributed identically.

Consider next the problem of estimating the error in a variable that cannot be measured directly but must be calculated based on results of other measurements. Suppose the computed value Y is a linear combination of the measured variables $\{y_i\}$, $Y = \alpha_1 y_1 + \alpha_2 y_2 + \cdots$. Let the random variables $y_1, y_2, \ldots$ have means $E(y_1), E(y_2), \ldots$ and variances $\sigma^2(y_1), \sigma^2(y_2), \ldots$. The variable Y has mean

$$E(Y) = \alpha_1 E(y_1) + \alpha_2 E(y_2) + \cdots$$

and variance (Cropley, 1978)

$$\sigma^2(Y) = \sum_{i=1}^{n} \alpha_i^2 \sigma^2(y_i) + 2 \sum_{i=1}^{n} \sum_{j=i+1}^{n} \alpha_i \alpha_j \text{ Cov } (y_i, y_j)$$

If the variables are uncorrelated and have the same variance, then

$$\sigma^2(Y) = \left(\sum_{i=1}^{n} \alpha_i^2 \right) \sigma^2$$

Next suppose the model relating Y to $\{y_i\}$ is nonlinear, but the errors are small and independent of one another. Then a change in Y is related to changes in y_i by

$$dY = \frac{\partial Y}{\partial y_1} dy_1 + \frac{\partial Y}{\partial y_2} dy_2 + \cdots$$

If the changes are indeed small, then the partial derivatives are constant among all the samples. Then the expected value of the change, $E(dY)$, is zero. The variances are given by the following equation (Baird, 1995; Box et al., 2005):

$$\sigma^2(dY) = \sum_{i=1}^{N} \left(\frac{\partial Y}{\partial y_i} \right)^2 \sigma_i^2$$

Thus, the variance of the desired quantity Y can be found. This gives an independent estimate of the errors in measuring the quantity Y from the errors in measuring each variable it depends upon.

Example Suppose one wants to measure the thermal conductivity of a solid (k). To do this, one needs to measure the heat flux (q), the thickness of the sample (d), and the temperature difference across the sample (ΔT). Each measurement has some error. The heat flux (q) may be the rate of electrical heat input ($\dot{Q}$) divided by the area (A), and both quantities are measured to some tolerance. The thickness of the sample is measured with some accuracy, and the temperatures are probably measured with a thermocouple to some accuracy. These measurements are combined, however, to obtain the thermal conductivity, and it is desired to know the error in the thermal conductivity. The formula is

$$k = \frac{d}{A \Delta T} \dot{Q}$$

The variance in the thermal conductivity is then

$$\sigma_k^2 = \left(\frac{k}{d} \right)^2 \sigma_d^2 + \left(\frac{k}{\dot{Q}} \right)^2 \sigma_{\dot{Q}}^2 + \left(\frac{k}{A} \right)^2 \sigma_A^2 + \left(\frac{k}{\Delta T} \right)^2 \sigma_{\Delta T}^2$$

FACTORIAL DESIGN OF EXPERIMENTS AND ANALYSIS OF VARIANCE

Statistically designed experiments consider, of course, the effect of primary variables, but they also consider the effect of extraneous variables and the interactions between variables, and they include a measure of the random error. Primary variables are those whose effect you wish to determine. These variables can be quantitative or qualitative. The quantitative variables are ones you may fit to a model in order to determine the model parameters (see the section "Least Squares"). Qualitative variables are ones you wish to know the effect of, but you do not try to quantify that effect other than to assign possible errors or magnitudes. Qualitative variables can be further subdivided into Type I variables, whose effect you wish to determine directly, and Type II variables, which contribute to the performance variability and whose effect you wish to average out. For example, if you are studying the effect of several catalysts on yield in a chemical reactor, each different type of catalyst would be a Type I variable because you would like to know the effect of each. However, each time the catalyst is prepared, the results are slightly different due to random variations; thus, you may have several batches of what purports to be the same catalyst. The variability between batches is a Type II variable. Since the ultimate use will require using different batches, you would like to know the overall effect including that variation, since knowing precisely the results from one batch of one catalyst might not be representative of the results obtained from all batches of the same catalyst. A randomized block design, incomplete block design, or Latin square design (Box et al., ibid.), for example, all keep the effect of experimental error in the blocked variables from influencing the effect of the primary variables. Other uncontrolled variables are accounted for by introducing randomization in parts of the experimental design. To study all variables and their interaction requires a factorial design, involving all possible combinations of each variable, or a fractional factorial design, involving only a selected set. Statistical techniques are then used to determine which are the important variables, what are the important interactions, and what the error is in estimating these effects. The discussion here is only a brief overview of the excellent book by Box et al. (2005).

Suppose we have two methods of preparing some product and we wish to see which treatment is best. When there are only two treatments, then the sampling analysis discussed in the section "Two-Population Test of Hypothesis for Means" can be used to deduce if the means of the two treatments differ significantly. When there are more treatments, the analysis is more detailed. Suppose the experimental results are arranged

as shown in the table: several measurements for each treatment. The goal is to see if the treatments differ significantly from each other; that is, whether their means are different when the samples have the same variance. The hypothesis is that the treatments are all the same, and the null hypothesis is that they are different. The statistical validity of the hypothesis is determined by an analysis of variance.

Estimating the Effect of Four Treatments

	Treatment			
	1	2	3	4
	—	—	—	—
	—	—	—	—
	—	—	—	—
		—	—	—
			—	—
				—
Treatment average	—	—	—	—
Grand average		—		

The data for $k = 4$ treatments is arranged in the table. For each treatment, there are n_t experiments and the outcome of the ith experiment with treatment t is called y_{ti}. Compute the treatment average

$$\bar{y}_t = \frac{\sum_{i=1}^{n_t} y_{ti}}{n_t}$$

Also compute the grand average

$$\bar{y} = \frac{\sum_{t=1}^{k} n_t \bar{y}_t}{N}, \quad N = \sum_{t=1}^{k} n_t$$

Next compute the sum of squares of deviations from the average within the tth treatment

$$S_t = \sum_{i=1}^{n_t} (y_{ti} - \bar{y}_t)^2$$

Since each treatment has n_t experiments, the number of degrees of freedom is $n_t - 1$. Then the sample variances are

$$s_t^2 = \frac{S_t}{n_t - 1}$$

The within-treatment sum of squares is

$$S_R = \sum_{t=1}^{k} S_t$$

and the within-treatment sample variance is

$$s_R^2 = \frac{S_R}{N - k}$$

Now, if there is no difference between treatments, a second estimate of σ^2 could be obtained by calculating the variation of the treatment averages about the grand average. Thus compute the between-treatment mean square

$$s_T^2 = \frac{S_T}{k-1}, \quad S_T = \sum_{t=1}^{k} n_t (\bar{y}_t - \bar{y})^2$$

Basically the test for whether the hypothesis is true or not hinges on a comparison of the within-treatment estimate s_R^2 (with $\nu_R = N - k$ degrees of freedom) with the between-treatment estimate s_T^2 (with $\nu_T = k - 1$ degrees of freedom). The test is made based on the F distribution for ν_R and ν_T degrees of freedom (Table 3-8).

Next consider the case that uses randomized blocking to eliminate the effect of some variable whose effect is of no interest, such as the batch-to-batch variation of the catalysts in the chemical reactor example. Suppose there are k treatments and n experiments in each treatment. The results from nk experiments can be arranged as shown in the block design table; within each block, the various treatments are applied in a random order. Compute the block average, the treatment average, as well as the grand average as before.

Block Design with Four Treatments and Five Blocks

Treatment	1	2	3	4	Block average
Block 1	—	—	—	—	—
Block 2	—	—	—	—	—
Block 3	—	—	—	—	—
Block 4	—	—	—	—	—
Block 5	—	—	—	—	—

The following quantities are needed for the analysis of variance table.

Name	Formula	dof
average	$S_A = nk\bar{y}^2$	1
blocks	$S_B = k \sum_{i=1}^{n} (\bar{y}_i - \bar{y})^2$	$n - 1$
treatments	$S_T = n \sum_{t=1}^{k} (\bar{y}_t - \bar{y})^2$	$k - 1$
residuals	$S_R = \sum_{t=1}^{k} \sum_{i=1}^{n} (y_{ti} - \bar{y}_i - \bar{y}_t + \bar{y})^2$	$(n-1)(k-1)$
total	$S = \sum_{t=1}^{k} \sum_{i=1}^{n} y_{ti}^2$	$N = nk$

The key test is again a statistical one, based on the value of

$$\frac{s_T^2}{s_R^2}, \quad s_T^2 = \frac{S_T}{k-1}, \quad s_R^2 = \frac{S_R}{(n-1)(k-1)}$$

and the F distribution for ν_R and ν_T degrees of freedom (Table 3-8). The assumption behind the analysis is that the variations are linear. See Box et al. (2005). There are ways to test this assumption as well as transformations to make if it is not true. Box et al. also give an excellent example of how the observations are broken down into a grand average, a block deviation, a treatment deviation, and a residual. For two-way factorial design in which the second variable is a real one rather than one you would like to block out, see Box et al.

To measure the effects of variables on a single outcome a factorial design is appropriate. In a two-level factorial design, each variable is considered at two levels only, a high and low value, often designated as a + and −. The two-level factorial design is useful for indicating trends, showing interactions, and it is also the basis for a fractional factorial design. As an example, consider a 2^3 factorial design with 3 variables and 2 levels for each. The experiments are indicated in the factorial design table.

Two-Level Factorial Design with Three Variables

	Variable		
Run	1	2	3
1	−	−	−
2	+	−	−
3	−	+	−
4	+	+	−
5	−	−	+
6	+	−	+
7	−	+	+
8	+	+	+

The main effects are calculated by calculating the difference between results from all high values of a variable and all low values of a variable; the result is divided by the number of experiments at each level. For example, for the first variable:

$$\text{Effect of variable 1} = \frac{[(y_2 + y_4 + y_6 + y_8) - (y_1 + y_3 + y_5 + y_7)]}{4}$$

Note that all observations are being used to supply information on each of the main effects and each effect is determined with the precision of a fourfold replicated difference. The advantage of a one-at-a-time experiment is the gain in precision if the variables are additive and the measure of nonadditivity if it occurs (Box et al., 2005).

Interaction effects between variables 1 and 2 are obtained by calculating the difference between the results obtained with the high and low value of 1 at the low value of 2 compared with the results obtained

with the high and low value 1 at the high value of 2. The 12-interaction is

$$\text{12-interaction} = \frac{[(y_4 - y_3 + y_8 - y_7) - (y_2 - y_1 + y_6 - y_5)]}{2}$$

The key step is to determine the errors associated with the effect of each variable and each interaction so that the significance can be determined. Thus, standard errors need to be assigned. This can be done by repeating the experiments, but it can also be done by using higher-order interactions (such as 123 interactions in a 2^4 factorial design). These are assumed negligible in their effect on the mean but can be used to estimate the standard error. Then, calculated effects that are large compared with the standard error are considered important, while those that are small compared with the standard error are considered to be due to random variations and are unimportant.

In a fractional factorial design one does only part of the possible experiments. When there are k variables, a factorial design requires 2^k experiments. When k is large, the number of experiments can be large; for $k = 5$, $2^5 = 32$. For a k this large, Box et al. (2005) do a fractional factorial design. In the fractional factorial design with $k = 5$, only 16 experiments are done. Cropley (1978) gives an example of how to combine heuristics and statistical arguments in application to kinetics mechanisms in chemical engineering.

DIMENSIONAL ANALYSIS

Dimensional analysis allows the engineer to reduce the number of variables that must be considered to model experiments or correlate data. Consider a simple example in which two variables F_1 and F_2 have the units of force and two additional variables L_1 and L_2 have the units of length. Rather than having to deduce the relation of one variable on the other three, $F_1 = \text{fn}(F_2, L_1, L_2)$, dimensional analysis can be used to show that the relation must be of the form $F_1/F_2 = \text{fn}(L_1/L_2)$. Thus considerable experimentation is saved. Historically, dimensional analysis can be done using the Rayleigh method or the Buckingham pi method. This brief discussion is equivalent to the Buckingham pi method but uses concepts from linear algebra; see Amundson, N. R., *Mathematical Methods in Chemical Engineering*, Prentice-Hall, Englewood Cliffs, N.J. (1966), p. 54, for further information.

The general problem is posed as finding the minimum number of variables necessary to define the relationship between n variables. Let $\{Q_i\}$ represent a set of fundamental units, like length, time, force, and so on. Let $[P_i]$ represent the dimensions of a physical quantity P_i; there are n physical quantities. Then form the matrix α_{ij}

	$[P_1]$	$[P_2]$	$\cdots$	$[P_n]$
Q_1	α_{11}	α_{12}	$\cdots$	α_{1n}
Q_2	α_{21}	α_{22}	$\cdots$	α_{2n}
$\cdots$				
Q_m	α_{m1}	α_{m2}	$\cdots$	α_{mn}

in which the entries are the number of times each fundamental unit appears in the dimensions $[P_i]$. The dimensions can then be expressed as follows.

$$[P_i] = Q_1^{\alpha_{1i}} Q_2^{\alpha_{2i}} \cdots Q_m^{\alpha_{mi}}$$

Let m be the rank of the α matrix. Then $p = n - m$ is the number of dimensionless groups that can be formed. One can choose m variables $\{P_i\}$ to be the basis and express the other p variables in terms of them, giving p dimensionless quantities.

Example: Buckingham Pi Method—Heat-Transfer Film Coefficient It is desired to determine a complete set of dimensionless groups with which to correlate experimental data on the film coefficient of heat transfer between the walls of a straight conduit with circular cross section and a fluid flowing in that conduit. The variables and the dimensional constant believed to be involved and their dimensions in the engineering system are given below:

Film coefficient = $h = (F/L\theta T)$
Conduit internal diameter = $D = (L)$
Fluid linear velocity = $V = (L/\theta)$
Fluid density = $\rho = (M/L^3)$
Fluid absolute viscosity = $\mu = (M/L\theta)$
Fluid thermal conductivity = $k = (F/\theta T)$
Fluid specific heat = $c_p = (FL/MT)$
Dimensional constant = $g_c = (ML/F\theta^2)$

The matrix α in this case is as follows.

		$[P_i]$							
		h	D	V	ρ	μ	k	C_p	g_c
	F	1	0	0	0	0	1	1	−1
	M	0	0	0	1	1	0	−1	1
Q_j	L	−1	1	1	−3	−1	0	1	1
	θ	−1	0	−1	0	−1	−1	0	−2
	T	−1	0	0	0	0	−1	−1	0

Here $m \le 5$, $n = 8$, $p \ge 3$. Choose D, V, μ, k, and g_c as the primary variables. By examining the 5 × 5 matrix associated with those variables, we can see that its determinant is not zero, so the rank of the matrix is $m = 5$; thus, $p = 3$. These variables are thus a possible basis set. The dimensions of the other three variables h, ρ, and C_p must be defined in terms of the primary variables. This can be done by inspection, although linear algebra can be used, too.

$$[h] = D^{-1}k^{+1}; \text{ thus } \frac{h}{D^{-1}k} = \frac{hD}{k} \text{ is a dimensionless group}$$

$$[\rho] = \mu^1 V^{-1} D^{-1}; \text{ thus } \frac{\rho}{\mu^1 V^{-1} D^{-1}} = \frac{\rho V D}{\mu} \text{ is a dimensionless group}$$

$$[C_p] = k^{+1}\mu^{-1}; \text{ thus } \frac{C_p}{k^{+1}\mu^{-1}} = \frac{C_p \mu}{k} \text{ is a dimensionless group}$$

Thus, the dimensionless groups are

$$\frac{[P_i]}{Q_1^{\alpha_{1i}} Q_2^{\alpha_{2i}} \cdots Q_m^{\alpha_{mi}}} : \frac{hD}{k}, \frac{\rho V D}{\mu}, \frac{C_p \mu}{k}$$

The dimensionless group hD/k is called the Nusselt number, N_{Nu}, and the group $C_p\mu/k$ is the Prandtl number, N_{Pr}. The group $DV\rho/\mu$ is the familiar Reynolds number, N_{Re}, encountered in fluid-friction problems. These three dimensionless groups are frequently used in heat-transfer-film-coefficient correlations. Functionally, their relation may be expressed as

$$\phi(N_{Nu}, N_{Pr}, N_{Re}) = 0 \tag{3-121}$$

or as

$$N_{Nu} = \phi_1(N_{Pr}, N_{Re})$$

TABLE 3-9 Dimensionless Groups in the Engineering System of Dimensions

Biot number	N_{Bi}	hL/k
Condensation number	N_{Co}	$(h/k)(\mu^2/\rho^2 g)^{1/3}$
Number used in condensation of vapors	N_{Cv}	$L^3\rho^2 g\lambda/k\mu\Delta t$
Euler number	N_{Eu}	$g_c(-dp)/\rho V^2$
Fourier number	N_{Fo}	$k\theta/\rho c L^2$
Froude number	N_{Fr}	V^2/Lg
Graetz number	N_{Gz}	wc/kL
Grashof number	N_{Gr}	$L^3\rho^2\beta g\Delta t/\mu^2$
Mach number	N_{Ma}	V/V_a
Nusselt number	N_{Nu}	hD/k
Peclet number	N_{Pe}	$DV\rho c/k$
Prandtl number	N_{Pr}	$c\mu/k$
Reynolds number	N_{Re}	$DV\rho/\mu$
Schmidt number	N_{Sc}	$\mu/\rho D_v$
Stanton number	N_{St}	$h/cV\rho$
Weber number	N_{We}	$LV^2\rho/\sigma g_c$

It has been found that these dimensionless groups may be correlated well by an equation of the type

$$hD/k = K(c_p\mu/k)^a(DV\rho/\mu)^b$$

in which K, a, and b are experimentally determined dimensionless constants. However, any other type of algebraic expression or perhaps simply a graphical relation among these three groups that accurately fits the experimental data would be an equally valid manner of expressing Eq. (3-121).

Naturally, other dimensionless groups might have been obtained in the example by employing a different set of five repeating quantities that would not form a dimensionless group among themselves. Some of these groups may be found among those presented in Table 3-9. Such a complete set of three dimensionless groups might consist of Stanton, Reynolds, and Prandtl numbers or of Stanton, Peclet, and Prandtl numbers. Also, such a complete set different from that obtained in the preceding example will result from a multiplication of appropriate powers of the Nusselt, Prandtl, and Reynolds numbers. For such a set to be complete, however, it must satisfy the condition that each of the three dimensionless groups be independent of the other two.

PROCESS SIMULATION

CLASSIFICATION

Process simulation refers to the activity in which mathematical systems of chemical processes and refineries are modeled with equations, usually on the computer. The usual distinction must be made between steady-state models and transient models, following the ideas presented in the introduction to this section. In a chemical process, of course, the process is nearly always in a transient mode, at some level of precision, but when the time-dependent fluctuations are below some value, a steady-state model can be formulated. This subsection presents briefly the ideas behind steady-state process simulation (also called flowsheeting), which are embodied in commercial codes. The transient simulations are important for designing the start-up of plants and are especially useful for the operation of chemical plants.

THERMODYNAMICS

The most important aspect of the simulation is that the thermodynamic data of the chemicals be modeled correctly. It is necessary to decide what equation of state to use for the vapor phase (ideal gas, Redlich-Kwong-Soave, Peng-Robinson, etc.) and what model to use for liquid activity coefficients [ideal solutions, solubility parameters, Wilson equation, nonrandom two liquid (NRTL), UNIFAC, etc.]. See Sec. 4, "Thermodynamics." It is necessary to consider mixtures of chemicals, and the interaction parameters must be predictable. The best case is to determine them from data, and the next-best case is to use correlations based on the molecular weight, structure, and normal boiling point. To validate the model, the computer results of vapor-liquid equilibria could be checked against experimental data to ensure their validity before the data are used in more complicated computer calculations.

PROCESS MODULES OR BLOCKS

At the first level of detail, it is not necessary to know the internal parameters for all the units, since what is desired is just the overall performance. For example, in a heat exchanger design, it suffices to know the heat duty, the total area, and the temperatures of the output streams; the details such as the percentage baffle cut, tube layout, or baffle spacing can be specified later when the details of the proposed plant are better defined. It is important to realize the level of detail modeled by a commercial computer program. For example, a chemical reactor could be modeled as an equilibrium reactor, in which the input stream is brought to a new temperature and pressure and the output stream is in chemical equilibrium at those new conditions. Or, it may suffice to simply specify the conversion, and the computer program will calculate the outlet compositions. In these cases, the model equations are algebraic ones, and you do not learn the volume of the reactor. A more complicated reactor might be a stirred tank reactor, and then you would have to specify kinetic information so that the simulation can be made, and one output would be either the volume of the reactor or the conversion possible in a volume you specify. Such models are also composed of sets of algebraic equations. A plug flow reactor is modeled as a set of ordinary differential equations as initial-value problems, and the computer program must use numerical methods to integrate them. See "Numerical Solution of Ordinary Differential Equations as Initial Value Problems." Kinetic information must be specified, and one learns the conversion possible in a given reactor volume, or, in some cases, the volume reactor that will achieve a given conversion. The simulation engineer determines what a reactor of a given volume will do for the specified kinetics and reactor volume. The design engineer, though, wants to achieve a certain result and wants to know the volume necessary. Simulation packages are best suited for the simulation engineer, and the design engineer must vary specifications to achieve the desired output.

Distillation simulations can be based on shortcut methods, using correlations based on experience, but more rigorous methods involve solving for the vapor-liquid equilibrium on each tray. The shortcut method uses relatively simple equations, and the rigorous method requires solution of huge sets of nonlinear equations. The computation time of the latter is significant, but the rigorous method may be necessary when the chemicals you wish to distill are not well represented in the correlations. Then the designer must specify the number of trays and determine the separation that is possible. This, of course, is not what he or she wants: the number of trays needed to achieve a specified objective. Thus, again, some adjustment of parameters is necessary in a design situation.

Absorption columns can be modeled in a plate-to-plate fashion (even if it is a packed bed) or as a packed bed. The former model is a set of nonlinear algebraic equations, and the latter model is an ordinary differential equation. Since streams enter at both ends, the differential equation is a two-point boundary value problem, and numerical methods are used (see "Numerical Solution of Ordinary Differential Equations as Initial-Value Problems").

If one wants to model a process unit that has significant flow variation, and possibly some concentration distributions as well, one can consider using computational fluid dynamics (CFD) to do so. These calculations are very time-consuming, though, so that they are often left until the mechanical design of the unit. The exception would occur when the flow variation and concentration distribution had a significant effect on the output of the unit so that mass and energy balances couldn't be made without it.

The process units are described in greater detail in other sections of the Handbook. In each case, parameters of the unit are specified (size, temperature, pressure, area, and so forth). In addition, in a computer simulation, the computer program must be able to take any input to the unit and calculate the output for those parameters. Since the entire calculation is done iteratively, there is no assurance that the

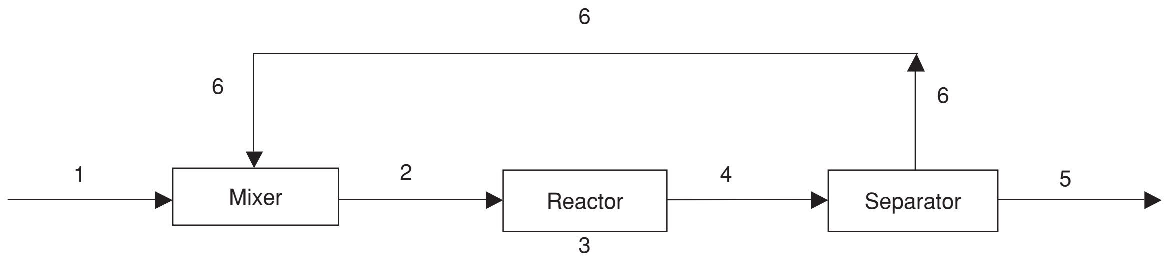

FIG. 3-67 Prototype flowsheet.

input stream is a "reasonable" one, so that the computer codes must be written to give some sort of output even when the input stream is unreasonable. This difficulty makes the iterative process even more complicated.

PROCESS TOPOLOGY

A chemical process usually consists of a series of units, such as distillation towers, reactors, and so forth (see Fig. 3-67). If the feed to the process is known and the operating parameters of the units are specified by the user, then one can begin with the first unit, take the process input, calculate the unit output, carry that output to the input of the next unit, and continue the process. However, if the process involves a recycle stream, as nearly all chemical processes do, then when the calculation is begun, it is discovered that the recycle stream is unknown. This situation leads to an iterative process: the flow rates, temperature, and pressure of the unknown recycle stream are guessed, and the calculations proceed as before. When one reaches the end of the process, where the recycle stream is formed to return to the first unit, it is necessary to check to see if the recycle stream is the same as assumed. If not, an iterative procedure must be used to cause convergence. Possible techniques are described in "Numerical Solutions of Nonlinear Equations in One Variable" and "Numerical Solution of Simultaneous Equations." The direct method (or successive substitution method) just involves calculating around the process over and over. The Wegstein method accelerates convergence for a single variable, and Broyden's method does the same for multiple variables. The Newton method can be used provided there is some way to calculate the derivatives (possibly by using a numerical derivative). Optimization methods can also be used (see "Optimization" in this section). In the description given here, the recycle stream is called the tear stream: this is the stream that must be guessed to begin the calculation. When there are multiple recycle streams, convergence is even more difficult, since more guesses are necessary, and what happens in one recycle stream may cause difficulties for the guesses in other recycle streams. See Seader (1985) and Mah (1990).

It is sometimes desired to control some stream by varying an operating parameter. For example, in a reaction/separation system, if there is an impurity that must be purged, a common objective is to set the purge fraction so that the impurity concentration into the reactor is kept at some moderate value. Commercial packages contain procedures for doing this using what are often called control blocks. However, this can also make the solution more difficult to find.

An alternative method of solving the equations is to solve them as simultaneous equations. In that case, one can specify the design variables and the desired specifications and let the computer figure out the process parameters that will achieve those objectives. It is possible to overspecify the system or to give impossible conditions. However, the biggest drawback to this method of simulation is that large sets (tens of thousands) of nonlinear algebraic equations must be solved simultaneously. As computers become faster, this is less of an impediment, provided efficient software is available.

Dynamic simulations are also possible, and these require solving differential equations, sometimes with algebraic constraints. If some parts of the process change extremely quickly when there is a disturbance, that part of the process may be modeled in the steady state for the disturbance at any instant. Such situations are called stiff, and the methods for them are discussed in "Numerical Solution of Ordinary Differential Equations as Initial-Value Problems." It must be realized, though, that a dynamic calculation can also be time-consuming, and sometimes the allowable units are lumped-parameter models that are simplifications of the equations used for the steady-state analysis. Thus, as always, the assumptions need to be examined critically before accepting the computer results.

COMMERCIAL PACKAGES

Computer programs are provided by many companies, and the models range from empirical models to deterministic models. For example, if one wanted to know the pressure drop in a piping network, one would normally use a correlation for friction factor as a function of Reynolds number to calculate the pressure drop in each segment. A sophisticated turbulence model of fluid flow is not needed in that case. As computers become faster, however, more and more models are deterministic. Since the commercial codes have been used by many customers, the data in them have been verified, but possibly not for the case you want to solve. Thus, you must test the thermodynamics correlations carefully. In 2005, there were a number of computer codes, but the company names change constantly. Here are a few of them for process simulation: Aspen Tech (Aspen Plus), Chemstations (CHEMCAD), Honeywell (UniSim Design), ProSim (ProSimPlus), and SimSci-Esseor (Pro II). The CAPE-OPEN project is working to make details as transferable as possible.

Michael M. Abbott, Ph.D. *Deceased; Professor Emeritus, Howard P. Isermann Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute (Section Coeditor)**

*Dr. Abbott died on May 31, 2006. This, his final contribution to the literature of chemical engineering, is deeply appreciated, as are his earlier contributions to the handbook.

THERMODYNAMIC ANALYSIS OF PROCESSES

Nomenclature and Units

Correlation- and application-specific symbols are not shown.

Symbol	Definition	SI units	U.S. Customary System units
A	Molar (or unit-mass) Helmholtz energy	J/mol [J/kg]	Btu/lb mol [Btu/lbm]
A	Cross-sectional area in flow	m^2	ft^2
$\hat{a}_i$	Activity of species i in solution	Dimensionless	Dimensionless
$\bar{a}_i$	Partial parameter, cubic equation of state		
B	2d virial coefficient, density expansion	cm^3/mol	cm^3/mol
$\bar{B}_i$	Partial molar second virial coefficient	cm^3/mol	cm^3/mol
$\hat{B}$	Reduced second virial coefficient		
C	3d virial coefficient, density expansion	cm^6/mol^2	cm^6/mol^2
$\hat{C}$	Reduced third virial coefficient		
D	4th virial coefficient, density expansion	cm^9/mol^3	cm^9/mol^3
B'	2d virial coefficient, pressure expansion	kPa^{-1}	kPa^{-1}
C'	3d virial coefficient, pressure expansion	kPa^{-2}	kPa^{-2}
D'	4th virial coefficient, pressure expansion	kPa^{-3}	kPa^{-3}
B_{ij}	Interaction 2d virial coefficient	cm^3/mol	cm^3/mol
C_{ijk}	Interaction 3d virial coefficient	cm^6/mol^2	cm^6/mol^2
C_P	Heat capacity at constant pressure	J/(mol·K)	Btu/(lb·mol·R)
C_V	Heat capacity at constant volume	J/(mol·K)	Btu/(lb·mol·R)
f_i	Fugacity of pure species i	kPa	psi
$\hat{f}_i$	Fugacity of species i in solution	kPa	psi
G	Molar (or unit-mass) Gibbs energy	J/mol [J/kg]	Btu/(lb·mol) [Btu/lbm]
g	Acceleration of gravity	m/s^2	ft/s^2
g	$\equiv G^E/RT$	Dimensionless	Dimensionless
H	Molar (or unit-mass) enthalpy	J/mol [J/kg]	Btu/(lb·mol) [Btu/lbm]
K_i	Equilibrium K value, y_i/x_i	Dimensionless	Dimensionless
K_j	Equilibrium constant for chemical reaction j	Dimensionless	Dimensionless
k_1	Henry's constant for solute species 1	kPa	psi
M	Molar or unit-mass solution property (A, G, H, S, U, V)		
$\mathbf{M}$	Mach number	Dimensionless	Dimensionless
M_i	Molar or unit-mass pure-species property ($A_i, G_i, H_i, S_i, U_i, V_i$)		
$\bar{M}_i$	Partial property of species i in solution ($\bar{A}_i, \bar{G}_i, \bar{H}_i, \bar{S}_i, \bar{U}_i, \bar{V}_i$)		
M^R	Residual thermodynamic property ($A^R, G^R, H^R, S^R, U^R, V^R$)		
M^E	Excess thermodynamic property ($A^E, G^E, H^E, S^E, U^E, V^E$)		
$\bar{M}_i^E$	Partial molar excess thermodynamic property		
ΔM	Property change of mixing ($\Delta A, \Delta G, \Delta H, \Delta S, \Delta U, \Delta V$)		
ΔM_j°	Standard property change of reaction j ($\Delta G_j^\circ, \Delta H_j^\circ, \Delta C_{P_j}^\circ$)		
m	Mass	kg	lbm
$\dot{m}$	Mass flow rate	kg/s	lbm/s
n	Number of moles		
$\dot{n}$	Molar flow rate		
n_i	Number of moles of species i		
P	Absolute pressure	kPa	psi
P_i^{sat}	Saturation or vapor pressure of species i	kPa	psi
Q	Heat	J	Btu
q	Volumetric flow rate	m^3/s	ft^3/s
$\dot{Q}$	Rate of heat transfer	J/s	Btu/s
R	Universal gas constant	J/(mol·K)	Btu/(lb·mol·R)
S	Molar (or unit-mass) entropy	J/(mol·K) [J/(kg·K)]	Btu/(lb·mol·R) [Btu/(lbm·R)]
$\dot{S}_G$	Rate of entropy generation, Eq. (4-151)	J/(K·s)	Btu/(R·s)
T	Absolute temperature	K	R
T_c	Critical temperature	K	R
U	Molar (or unit-mass) internal energy	J/mol [J/kg]	Btu/(lb·mol) [Btu/lbm]
u	Fluid velocity	m/s	ft/s
V	Molar (or unit-mass) volume	m^3/mol [m^3/kg]	ft^3/(lb·mol) [ft^3/lbm]
W	Work	J	Btu
W_s	Shaft work for flow process	J	Btu
$\dot{W}_s$	Shaft power for flow process	J/s	Btu/s
x_i	Mole fraction in general		
x_i	Mole fraction of species i in liquid phase		
y_i	Mole fraction of species i in vapor phase		
Z	Compressibility factor	Dimensionless	Dimensionless
z	Elevation above a datum level	m	ft
	Superscripts		
E	Denotes excess thermodynamic property		
id	Denotes value for an ideal solution		
ig	Denotes value for an ideal gas		
l	Denotes liquid phase		
lv	Denotes phase transition, liquid to vapor		
R	Denotes residual thermodynamic property		
t	Denotes total value of property		
v	Denotes vapor phase		
∞	Denotes value at infinite dilution		
	Subscripts		
c	Denotes value for the critical state		
cv	Denotes the control volume		
fs	Denotes flowing streams		
n	Denotes the normal boiling point		
r	Denotes a reduced value		
rev	Denotes a reversible process		
	Greek Letters		
α, β	As superscripts, identify phases		
β	Volume expansivity	K^{-1}	$°R^{-1}$
ε_j	Reaction coordinate for reaction j	mol	lb·mol
$\Gamma_i(T)$	Defined by Eq. (4-196)	J/mol	Btu/(lb·mol)
γ	Heat capacity ratio C_P/C_V	Dimensionless	Dimensionless
γ_i	Activity coefficient of species i in solution	Dimensionless	Dimensionless
κ	Isothermal compressibility	kPa^{-1}	psi^{-1}
μ_i	Chemical potential of species i	J/mol	Btu/(lb·mol)
$\nu_{i,j}$	Stoichiometric number of species i in reaction j	Dimensionless	Dimensionless
ρ	Molar density	mol/m^3	$lb·mol/ft^3$
σ	As subscript, denotes a heat reservoir		
Φ_i	Defined by Eq. (4-304)	Dimensionless	Dimensionless
ϕ_i	Fugacity coefficient of pure species i	Dimensionless	Dimensionless
$\hat{\phi}_i$	Fugacity coefficient of species i in solution	Dimensionless	Dimensionless
ω	Acentric factor	Dimensionless	Dimensionless

INTRODUCTION

Thermodynamics is the branch of science that lends substance to the principles of energy transformation in macroscopic systems. The general restrictions shown by experience to apply to all such transformations are known as the laws of thermodynamics. These laws are primitive; they cannot be derived from anything more basic.

The first law of thermodynamics states that energy is conserved, that although it can be altered in form and transferred from one place to another, the total quantity remains constant. Thus the first law of thermodynamics depends on the concept of energy, but conversely energy is an *essential* thermodynamic function because it allows the first law to be formulated. This coupling is characteristic of the primitive concepts of thermodynamics.

The words *system* and *surroundings* are similarly coupled. A system can be an object, a quantity of matter, or a region of space, selected for study and set apart (mentally) from everything else, which is called the surroundings. An envelope, imagined to enclose the system and to separate it from its surroundings, is called the *boundary* of the system.

Attributed to this boundary are special properties which may serve either to *isolate* the system from its surroundings or to provide for *interaction* in specific ways between the system and surroundings. An isolated system exchanges neither matter nor energy with its surroundings. If a system is not isolated, its boundaries may permit exchange of matter or energy or both with its surroundings. If the exchange of matter is allowed, the system is said to be *open*; if only energy and not matter may be exchanged, the system is *closed* (but not isolated), and its mass is constant.

When a system is isolated, it cannot be affected by its surroundings. Nevertheless, changes may occur within the system that are detectable with measuring instruments such as thermometers and pressure gauges. However, such changes cannot continue indefinitely, and the system must eventually reach a final static condition of *internal equilibrium.*

For a closed system which interacts with its surroundings, a final static condition may likewise be reached such that the system is not only internally at equilibrium but also in *external equilibrium* with its surroundings.

The concept of equilibrium is central in thermodynamics, for associated with the condition of internal equilibrium is the concept of *state*. A system has an identifiable, reproducible state when all its *properties*, such as temperature T, pressure P, and molar volume V, are fixed. The concepts of *state* and *property* are again coupled. One can equally well say that the properties of a system are fixed by its state. Although the properties T, P, and V may be detected with measuring instruments, the existence of the *primitive* thermodynamic properties (see postulates 1 and 3 following) is recognized much more indirectly. The number of properties for which values must be specified in order to fix the state of a system depends on the nature of the system, and is ultimately determined from experience.

When a system is displaced from an equilibrium state, it undergoes a *process*, a change of state, which continues until its properties attain new equilibrium values. During such a process, the system may be caused to interact with its surroundings so as to interchange energy in the forms of heat and work and so to produce in the system changes considered desirable for one reason or another. A process that proceeds so that the system is never displaced more than differentially from an equilibrium state is said to be *reversible*, because such a process can be reversed at any point by an infinitesimal change in external conditions, causing it to retrace the initial path in the opposite direction.

Thermodynamics finds its origin in experience and experiment, from which are formulated a few postulates that form the foundation of the subject. The first two deal with energy.

POSTULATE 1

There exists a form of energy, known as **internal energy,** *which for systems at internal equilibrium is an intrinsic property of the system, functionally related to the measurable coordinates that characterize the system.*

POSTULATE 2 (FIRST LAW OF THERMODYNAMICS)

The **total** *energy of any system and its surroundings is conserved.*

Internal energy is quite distinct from such external forms as the kinetic and potential energies of macroscopic bodies. Although it is a macroscopic property, characterized by the macroscopic coordinates T and P, internal energy finds its origin in the kinetic and potential energies of molecules and submolecular particles. In applications of the first law of thermodynamics, all forms of energy must be considered, including the internal energy. It is therefore clear that postulate 2 depends on postulate 1. For an isolated system the first law requires that its energy be constant. For a closed (but not isolated) system, the first law requires that energy changes of the system be exactly compensated by energy changes in the surroundings. For such systems energy is exchanged between a system and its surroundings in two forms: heat and work.

Heat is energy crossing the system boundary under the influence of a temperature difference or gradient. A quantity of heat Q represents an amount of energy in transit between a system and its surroundings, and is not a property of the system. The convention with respect to sign makes numerical values of Q positive when heat is added to the system and negative when heat leaves the system.

Work is again energy in transit between a system and its surroundings, but resulting from the displacement of an external force acting on the system. Like heat, a quantity of work W represents an amount of energy, and is not a property of the system. The sign convention, analogous to that for heat, makes numerical values of W positive when work is done on the system by the surroundings and negative when work is done on the surroundings by the system.

When applied to closed (constant-mass) systems in which only internal-energy changes occur, the first law of thermodynamics is expressed mathematically as

$$dU^t = dQ + dW \tag{4-1}$$

where U^t is the total internal energy of the system. Note that dQ and dW, differential *quantities* representing energy exchanges between the system and its surroundings, serve to account for the energy change of the surroundings. On the other hand, dU^t is directly the differential *change* in internal energy of the system. Integration of Eq. (4-1) gives for a finite process

$$\Delta U^t = Q + W \tag{4-2}$$

where ΔU^t is the finite change given by the difference between the final and initial values of U^t. The heat Q and work W are finite quantities of heat and work; they are not properties of the system or functions of the thermodynamic coordinates that characterize the system.

POSTULATE 3

There exists a property called **entropy,** *which for systems at internal equilibrium is an intrinsic property of the system, functionally related to the measurable coordinates that characterize the system. For* **reversible** *processes, changes in this property may be calculated by the equation*

$$dS^t = \frac{dQ_{\text{rev}}}{T} \tag{4-3}$$

where S^t *is the total entropy of the system and* T *is the absolute temperature of the system.*

POSTULATE 4 (SECOND LAW OF THERMODYNAMICS)

The entropy change of any system and its surroundings, **considered together,** *resulting from any real process is positive, approaching zero when the process approaches reversibility.*

In the same way that the first law of thermodynamics cannot be formulated without the prior recognition of internal energy as a property, so also the second law can have no complete and quantitative expression without a prior assertion of the existence of entropy as a property.

The second law requires that the entropy of an isolated system either increase or, in the limit where the system has reached an equilibrium state, remain constant. For a closed (but not isolated) system it requires that any entropy decrease in either the system or its surroundings be more than compensated by an entropy increase in the other part, or that in the limit where the process is reversible, the total entropy of the system plus its surroundings be constant.

The fundamental thermodynamic properties that arise in connection with the first and second laws of thermodynamics are internal energy and entropy. These properties together with the two laws for which they are essential apply to all types of systems. However, different types of systems are characterized by different sets of measurable coordinates or variables. The type of system most commonly encountered in chemical technology is one for which the primary characteristic variables are temperature T, pressure P, molar volume V, and composition, not all of which are necessarily independent. Such systems are usually made up of fluids (liquid or gas) and are called *PVT* systems.

For closed systems of this kind the work of a *reversible* process may always be calculated from

$$dW_{\text{rev}} = -P\,dV^t \tag{4-4}$$

where P is the absolute pressure and V^t is the total volume of the system. This equation follows directly from the definition of mechanical work.

POSTULATE 5

The macroscopic properties of homogeneous PVT *systems at internal equilibrium can be expressed as functions of temperature, pressure, and composition only.*

This postulate imposes an idealization, and is the basis for all subsequent property relations for *PVT* systems. The *PVT* system serves as a satisfactory model in an enormous number of practical applications. In accepting this model one assumes that the effects of fields (e.g., electric, magnetic, or gravitational) are negligible and that surface and viscous shear effects are unimportant.

Temperature, pressure, and composition are thermodynamic coordinates representing conditions imposed upon or exhibited by the system, and the functional dependence of the thermodynamic properties on these conditions is determined by experiment. This is quite direct for molar or specific volume V, which can be measured, and leads immediately to the conclusion that there exists an *equation of state* relating molar volume to temperature, pressure, and composition for any particular homogeneous *PVT* system. The equation of state is a primary tool in applications of thermodynamics.

Postulate 5 affirms that the other molar or specific thermodynamic properties of *PVT* systems, such as internal energy U and entropy S, are also functions of temperature, pressure, and composition. These molar or unit-mass properties, represented by the plain symbols V, U, and S, are independent of system size and are called *intensive*. Temperature, pressure, and the composition variables, such as mole fraction, are also intensive. Total-system properties (V^t, U^t, S^t) do depend on system size and are *extensive*. For a system containing n mol of fluid, $M^t = nM$, where M is a molar property.

Applications of the thermodynamic postulates necessarily involve the abstract quantities of internal energy and entropy. The solution of any problem in applied thermodynamics is therefore found through these quantities.

VARIABLES, DEFINITIONS, AND RELATIONSHIPS

Consider a single-phase closed system in which there are no chemical reactions. Under these restrictions the composition is fixed. If such a system undergoes a differential, reversible process, then by Eq. (4-1)

$$dU^t = dQ_{\text{rev}} + dW_{\text{rev}}$$

Substitution for dQ_{rev} and dW_{rev} by Eqs. (4-3) and (4-4) gives

$$dU^t = T\,dS^t - P\,dV^t$$

Although derived for a *reversible* process, this equation relates properties only and is valid for *any* change between equilibrium states in a closed system. It is equally well written as

$$d(nU) = T\,d(nS) - P\,d(nV) \tag{4-5}$$

where n is the number of moles of fluid in the system and is constant for the special case of a closed, nonreacting system. Note that

$$n \equiv n_1 + n_2 + n_3 + \cdots = \sum_i n_i$$

where i is an index identifying the chemical species present. When U, S, and V represent *specific* (unit-mass) properties, n is replaced by m.

Equation (4-5) shows that for a single-phase, nonreacting, closed system, $nU = u(nS, nV)$.

Then $$d(nU) = \left[\frac{\partial(nU)}{\partial(nS)}\right]_{nV,n} d(nS) + \left[\frac{\partial(nU)}{\partial(nV)}\right]_{nS,n} d(nV)$$

where subscript n indicates that all mole numbers n_i (and hence n) are held constant. Comparison with Eq. (4-5) shows that

$$\left[\frac{\partial(nU)}{\partial(nS)}\right]_{nV,n} = T \quad \text{and} \quad \left[\frac{\partial(nU)}{\partial(nV)}\right]_{nS,n} = -P$$

For an **open** single-phase system, we assume that $nU = \mathcal{U}(nS, nV, n_1, n_2, n_3, \ldots)$. In consequence,

$$d(nU) = \left[\frac{\partial(nU)}{\partial(nS)}\right]_{nV,n} d(nS) + \left[\frac{\partial(nU)}{\partial(nV)}\right]_{nS,n} d(nV) + \sum_i \left[\frac{\partial(nU)}{\partial n_i}\right]_{nS,nV,n_j} dn_i$$

where the summation is over all species present in the system and subscript n_j indicates that all mole numbers are held constant except the ith. Define

$$\mu_i \equiv \left[\frac{\partial(nU)}{\partial n_i}\right]_{nS,nV,n_j}$$

The expressions for T and $-P$ of the preceding paragraph and the definition of μ_i allow replacement of the partial differential coefficients in the preceding equation by T, $-P$, and μ_i. The result is Eq. (4-6) of Table 4-1, where important equations of this section are collected. Equation (4-6) is the **fundamental property relation** for single-phase *PVT* systems, from which all other equations connecting properties of

TABLE 4-1 Mathematical Structure of Thermodynamic Property Relations

Primary thermodynamic functions		Fundamental property relations		For homogeneous systems of constant composition		Maxwell equations	
$U = TS - PV + \sum_i x_i \mu_i$	(4-7)	$d(nU) = T\,d(nS) - P\,d(nV) + \sum_i \mu_i\,dn_i$	(4-6)	$dU = T\,dS - P\,dV$	(4-14)	$\left(\frac{\partial T}{\partial V}\right)_S = -\left(\frac{\partial P}{\partial S}\right)_V$	(4-18)
$H \equiv U + PV$	(4-8)	$d(nH) = T\,d(nS) + nV\,dP + \sum_i \mu_i\,dn_i$	(4-11)	$dH = T\,dS + V\,dP$	(4-15)	$\left(\frac{\partial T}{\partial P}\right)_S = \left(\frac{\partial V}{\partial S}\right)_P$	(4-19)
$A \equiv U - TS$	(4-9)	$d(nA) = -nS\,dT - P\,d(nV) + \sum_i \mu_i\,dn_i$	(4-12)	$dA = -S\,dT - P\,dV$	(4-16)	$\left(\frac{\partial P}{\partial T}\right)_V = \left(\frac{\partial S}{\partial V}\right)_T$	(4-20)
$G \equiv H - TS$	(4-10)	$d(nG) = -nS\,dT + nV\,dP + \sum_i \mu_i\,dn_i$	(4-13)	$dG = -S\,dT + V\,dP$	(4-17)	$\left(\frac{\partial V}{\partial T}\right)_P = -\left(\frac{\partial S}{\partial P}\right)_T$	(4-21)

U, *H*, and *S* as functions of *T* and *P* or *T* and *V*		Partial derivatives		Total derivatives	
$dH = \left(\frac{\partial H}{\partial T}\right)_P dT + \left(\frac{\partial H}{\partial P}\right)_T dP$	(4-22)	$\left(\frac{\partial H}{\partial T}\right)_P = T\left(\frac{\partial S}{\partial T}\right)_P = C_P$	(4-28)	$dH = C_P\,dT + \left[V - T\left(\frac{\partial V}{\partial T}\right)_P\right]dP$	(4-32)
$dS = \left(\frac{\partial S}{\partial T}\right)_P dT + \left(\frac{\partial S}{\partial P}\right)_T dP$	(4-23)	$\left(\frac{\partial H}{\partial P}\right)_T = T\left(\frac{\partial S}{\partial P}\right)_T + V = V - T\left(\frac{\partial V}{\partial T}\right)_P$	(4-29)	$dS = \frac{C_P}{T}\,dT - \left(\frac{\partial V}{\partial T}\right)_P dP$	(4-33)
$dU = \left(\frac{\partial U}{\partial T}\right)_V dT + \left(\frac{\partial U}{\partial V}\right)_T dV$	(4-24)	$\left(\frac{\partial U}{\partial T}\right)_V = T\left(\frac{\partial S}{\partial T}\right)_V = C_V$	(4-30)	$dU = C_V\,dT + \left[T\left(\frac{\partial P}{\partial T}\right)_V - P\right]dV$	(4-34)
$dS = \left(\frac{\partial S}{\partial T}\right)_V dT + \left(\frac{\partial S}{\partial V}\right)_T dV$	(4-25)	$\left(\frac{\partial U}{\partial V}\right)_T = T\left(\frac{\partial S}{\partial V}\right)_T - P = T\left(\frac{\partial P}{\partial T}\right)_V - P$	(4-31)	$dS = \frac{C_V}{T}\,dT + \left(\frac{\partial P}{\partial T}\right)_V dV$	(4-35)

$U \equiv$ Internal energy; $H \equiv$ enthalpy; $A \equiv$ Helmoholtz energy; $G \equiv$ Gibbs energy.

such systems are derived. The quantity μ_i is called the *chemical potential* of species i, and it plays a vital role in the thermodynamics of phase and chemical equilibria.

Additional property relations follow directly from Eq. (4-6). Because $n_i = x_i n$, where x_i is the mole fraction of species i, this equation may be rewritten as

$$d(nU) - T\,d(nS) + P\,d(nV) - \sum_i \mu_i\,d(x_i n) = 0$$

Expansion of the differentials and collection of like terms yield

$$\left[dU - T\,dS + P\,dV - \sum_i \mu_i\,dx_i\right]n + \left[U - TS + PV - \sum_i x_i\mu_i\right]dn = 0$$

Because n and dn are independent and arbitrary, the terms in brackets must separately be zero. This provides two useful equations:

$$dU = T\,dS - P\,dV + \sum_i \mu_i\,dx_i \qquad U = TS - PV + \sum_i x_i\mu_i$$

The first is similar to Eq. (4-6). However, Eq. (4-6) applies to a system of n mol where n may vary. Here, however, n is unity and invariant. It is therefore subject to the constraints $\sum_i x_i = 1$ and $\sum_i dx_i = 0$. Mole fractions are not independent of one another, whereas the mole numbers in Eq. (4-6) are.

The second of the preceding equations dictates the possible combinations of terms that may be defined as additional primary functions. Those in common use are shown in Table 4-1 as Eqs. (4-7) through (4-10). Additional thermodynamic properties are related to these and arise by arbitrary definition.

Multiplication of Eq. (4-8) of Table 4-1 by n and differentiation yield the general expression

$$d(nH) = d(nU) + P\,d(nV) + nV\,dP$$

Substitution for $d(nU)$ by Eq. (4-6) reduces this result to Eq. (4-11). The total differentials of nA and nG are obtained similarly and are expressed by Eqs. (4-12) and (4-13). These equations and Eq. (4-6) are equivalent forms of the fundamental property relation, and appear under that heading in Table 4-1. Each expresses a total property—nU, nH, nA, and nG—as a function of a particular set of independent variables, called the *canonical variables* for the property. The choice of which equation to use in a particular application is dictated by convenience. However, the Gibbs energy G is special, because of its relation to the canonical variables T, P, and $\{n_i\}$, the variables of primary interest in chemical processing. Another set of equations results from the substitutions $n = 1$ and $n_i = x_i$. The resulting equations are of course less general than their parents. Moreover, because the mole fractions are not independent, mathematical operations requiring their independence are invalid.

CONSTANT-COMPOSITION SYSTEMS

For 1 mol of a homogeneous fluid of constant composition, Eqs. (4-6) and (4-11) through (4-13) simplify to Eqs. (4-14) through (4-17) of Table 4-1. Because these equations are *exact differential expressions*, application of the reciprocity relation for such expressions produces the common Maxwell relations as described in the subsection "Multivariable Calculus Applied to Thermodynamics" in Sec. 3. These are Eqs. (4-18) through (4-21) of Table 4-1, in which the partial derivatives are taken with composition held constant.

U*, *H*, and *S* as Functions of *T* and *P* or *T* and *V At constant composition, molar thermodynamic properties can be considered functions of T and P (postulate 5). Alternatively, because V is related to T and P through an equation of state, V can serve rather than P as the second independent variable. The useful equations for the total differentials of U, H, and S that result are given in Table 4-1 by Eqs. (4-22) through (4-25). The obvious next step is substitution for the partial differential coefficients in favor of measurable quantities. This purpose is served by definition of two *heat capacities*, one at constant pressure and the other at constant volume:

$$C_P \equiv \left(\frac{\partial H}{\partial T}\right)_P \tag{4-26}$$

$$C_V \equiv \left(\frac{\partial U}{\partial T}\right)_V \tag{4-27}$$

Both are properties of the material and functions of temperature, pressure, and composition.

Equation (4-15) of Table 4-1 may be divided by dT and restricted to constant P, yielding $(\partial H/\partial T)_P$ as given by the first equality of Eq. (4-28). Division of Eq. (4-15) by dP and restriction to constant T yield $(\partial H/\partial P)_T$ as given by the first equality of Eq. (4-29). Equation (4-28) is completed by Eq. (4-26), and Eq. (4-29) is completed by Eq. (4-21). Similarly, equations for $(\partial U/\partial T)_V$ and $(\partial U/\partial V)_T$ derive from Eq. (4-14), and these with Eqs. (4-27) and (4-20) yield Eqs. (4-30) and (4-31) of Table 4-1.

Equations (4-22), (4-26), and (4-29) combine to yield Eq. (4-32); Eqs. (4-23), (4-28), and (4-21) to yield Eq. (4-33); Eqs. (4-24), (4-27), and (4-31) to yield Eq. (4-34); and Eqs. (4-25), (4-30), and (4-20) to yield Eq. (4-35).

Equations (4-32) and (4-33) are general expressions for the enthalpy and entropy of homogeneous fluids *at constant composition* as functions of T and P. Equations (4-34) and (4-35) are general expressions for the internal energy and entropy of homogeneous fluids *at constant composition* as functions of temperature and molar volume. The coefficients of dT, dP, and dV are all composed of measurable quantities.

The Ideal Gas Model An ideal gas is a model gas comprising imaginary molecules of zero volume that do not interact. Its PVT behavior is represented by the simplest of equations of state $PV^{ig} = RT$, where R is a universal constant, values of which are given in Table 1-9. The following partial derivatives, all taken at constant composition, are obtained from this equation:

$$\left(\frac{\partial P}{\partial T}\right)_V = \frac{R}{V^{ig}} = \frac{P}{T} \qquad \left(\frac{\partial V^{ig}}{\partial T}\right)_P = \frac{R}{P} = \frac{V^{ig}}{T} \qquad \left(\frac{\partial P}{\partial V}\right)_T = -\frac{P}{V^{ig}}$$

The first two of these relations when substituted appropriately into Eqs. (4-29) and (4-31) of Table 4-1 lead to very simple expressions for ideal gases:

$$\left(\frac{\partial U^{ig}}{\partial V}\right)_T = \left(\frac{\partial H^{ig}}{\partial P}\right)_T = 0 \qquad \left(\frac{\partial S^{ig}}{\partial P}\right)_T = -\frac{R}{P} \qquad \left(\frac{\partial S^{ig}}{\partial V}\right)_T = \frac{R}{V^{ig}}$$

Moreover, Eqs. (4-32) through (4-35) become

$$dH^{ig} = C_P^{ig}\,dT \qquad dS^{ig} = \frac{C_P^{ig}}{T}\,dT - \frac{R}{P}\,dP$$

$$dU^{ig} = C_V^{ig}\,dT \qquad dS^{ig} = \frac{C_V^{ig}}{T}\,dT + \frac{R}{V^{ig}}\,dV$$

In these equations V^{ig}, U^{ig}, C_V^{ig}, H^{ig}, C_P^{ig}, and S^{ig} are ideal gas state values—the values that a PVT system would have were the ideal gas equation the true equation of state. They apply equally to pure species and to constant-composition mixtures, and they show that U^{ig}, C_V^{ig}, H^{ig}, and C_P^{ig}, are functions of temperature only, independent of P and V. The entropy, however, is a function of both T and P or of both T and V. Regardless of composition, the ideal gas volume is given by $V^{ig} = RT/P$, and it provides the basis for comparison with true molar volumes through the *compressibility factor* Z. By definition,

$$Z \equiv \frac{V}{V^{ig}} = \frac{V}{RT/P} = \frac{PV}{RT} \tag{4-36}$$

The ideal gas state properties of mixtures are directly related to the ideal gas state properties of the constituent pure species. For those properties that are independent of P—U^{ig}, H^{ig}, C_V^{ig}, and C_P^{ig}—the mixture property is the sum of the properties of the pure constituent species, each weighted by its mole fraction:

$$M^{ig} = \sum_i y_i M_i^{ig} \tag{4-37}$$

where M^{ig} can represent any of the properties listed. For the entropy, which is a function of both T and P, an additional term is required to account for the difference in partial pressure of a species between its pure state and its state in a mixture:

$$S^{ig} = \sum_i y_i S_i^{ig} - R\sum_i y_i \ln y_i \tag{4-38}$$

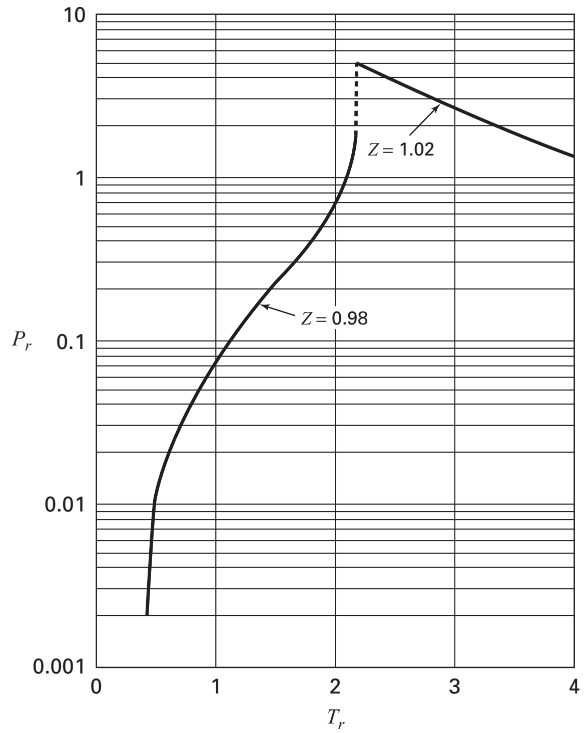

FIG. 4-1 Region where Z lies between 0.98 and 1.02, and the ideal-gas equation is a reasonable approximation. [*Smith, Van Ness, and Abbott*, Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 104, McGraw-Hill, New York (2005).*]

For the Gibbs energy, $G^{ig} = H^{ig} - TS^{ig}$; whence by Eqs. (4-37) and (4-38):

$$G^{ig} = \sum_i y_i G_i^{ig} + RT\sum_i y_i \ln y_i \tag{4-39}$$

The ideal gas model may serve as a reasonable approximation to reality under conditions indicated by Fig. 4-1.

Residual Properties The differences between true and ideal gas state properties are defined as residual properties M^R:

$$M^R \equiv M - M^{ig} \tag{4-40}$$

where M is the molar value of an extensive thermodynamic property of a fluid in its actual state and M^{ig} is its corresponding ideal gas state value at the same T, P, and composition. Residual properties depend on interactions *between* molecules and not on characteristics of individual molecules. Because the ideal gas state presumes the absence of molecular interactions, residual properties reflect deviations from ideality. The most commonly used residual properties are as follows:

Residual volume $V^R \equiv V - V^{ig}$ Residual enthalpy $H^R \equiv H - H^{ig}$

Residual entropy $S^R \equiv S - S^{ig}$ Residual Gibbs energy $G^R \equiv G - G^{ig}$

Useful relations connecting these residual properties derive from Eq. (4-17), an alternative form of which follows from the mathematical identity:

$$d\left(\frac{G}{RT}\right) \equiv \frac{1}{RT}\,dG - \frac{G}{RT^2}\,dT$$

Substitution for dG by Eq. (4-17) and for G by Eq. (4-10) gives, after algebraic reduction,

$$d\left(\frac{G}{RT}\right) = \frac{V}{RT}\,dP - \frac{H}{RT^2}\,dT \tag{4-41}$$

This equation may be written for the special case of an ideal gas and subtracted from Eq. (4-41) itself, yielding

$$d\left(\frac{G^R}{RT}\right) = \frac{V^R}{RT}\,dP - \frac{H^R}{RT^2}\,dT \tag{4-42}$$

As a consequence,

$$\frac{V^R}{RT} = \left[\frac{\partial(G^R/RT)}{\partial P}\right]_T \tag{4-43}$$

and

$$\frac{H^R}{RT} = -T\left[\frac{\partial(G^R/RT)}{\partial T}\right]_P \tag{4-44}$$

Equation (4-43) provides a direct link to PVT correlations through the compressibility factor Z as given by Eq. (4-36). Thus, with $V = ZRT/P$,

$$V^R \equiv V - V^{ig} = \frac{ZRT}{P} - \frac{RT}{P} = \frac{RT}{P}(Z-1)$$

This equation in combination with a rearrangement of Eq. (4-43) yields

$$d\left(\frac{G^R}{RT}\right) = \frac{V^R}{RT}\,dP = (Z-1)\,\frac{dP}{P} \qquad \text{(constant } T\text{)}$$

Integration from $P = 0$ to arbitrary pressure P gives

$$\frac{G^R}{RT} = \int_0^P (Z-1)\,\frac{dP}{P} \qquad \text{(constant } T\text{)} \tag{4-45}$$

Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 210–211, McGraw-Hill, New York (2005)] show that it is permissible here to set the lower limit of integration $(G^R/RT)_{P=0}$ equal to zero. Note also that the integrand $(Z-1)/P$ remains finite as $P \to 0$. Differentiation of Eq. (4-45) with respect to T in accord with Eq. (4-44) gives

$$\frac{H^R}{RT} = -T\int_0^P \left(\frac{\partial Z}{\partial T}\right)_P \frac{dP}{P} \qquad \text{(constant } T\text{)} \tag{4-46}$$

Because $G = H - TS$ and $G^{ig} = H^{ig} - TS^{ig}$, then by difference, $G^R = H^R - TS^R$, and

$$\frac{S^R}{R} = \frac{H^R}{RT} - \frac{G^R}{RT} \tag{4-47}$$

Equations (4-45) through (4-47) provide the basis for calculation of residual properties from PVT correlations. They may be put into *generalized* form by substitution of the relationships

$$P = P_c P_r \qquad T = T_c T_r$$
$$dP = P_c\,dP_r \qquad dT = T_c\,dT_r$$

The resulting equations are

$$\frac{G^R}{RT} = \int_0^{P_r} (Z-1)\,\frac{dP_r}{P_r} \tag{4-48}$$

$$\frac{H^R}{RT_c} = -T_r^2\int_0^{P_r} \left(\frac{\partial Z}{\partial T_r}\right)_{P_r} \frac{dP_r}{P_r} \tag{4-49}$$

The terms on the right sides of these equations depend only on the upper limit P_r of the integrals and on the reduced temperature at which they are evaluated. Thus, values of G^R/RT and H^R/RT_c may be determined once and for all at any reduced temperature and pressure from generalized compressibility factor data.

PROPERTY CALCULATIONS FOR GASES AND VAPORS

The most satisfactory calculation procedure for the thermodynamic properties of gases and vapors is based on ideal gas state heat capacities and residual properties. Of primary interest are the enthalpy and entropy; these are given by rearrangement of the residual property definitions:

$$H = H^{ig} + H^R \quad \text{and} \quad S = S^{ig} + S^R$$

These are simple sums of the ideal gas and residual properties, evaluated separately.

EVALUATION OF ENTHALPY AND ENTROPY IN THE IDEAL GAS STATE

For the ideal gas state at constant composition:

$$dH^{ig} = C_P^{ig}\,dT \quad \text{and} \quad dS^{ig} = C_P^{ig}\,\frac{dT}{T} - R\,\frac{dP}{P}$$

Integration from an initial ideal gas *reference state* at conditions T_0 and P_0 to the ideal gas state at T and P gives

$$H^{ig} = H_0^{ig} + \int_{T_0}^{T} C_P^{ig}\,dT$$

$$S^{ig} = S_0^{ig} + \int_{T_0}^{T} C_P^{ig}\,\frac{dT}{T} - R\ln\frac{P}{P_0}$$

Substitution into the equations for H and S yields

$$H = H_0^{ig} + \int_{T_0}^{T} C_P^{ig}\,dT + H^R \tag{4-50}$$

$$S = S_0^{ig} + \int_{T_0}^{T} C_P^{ig}\,\frac{dT}{T} - R\ln\frac{P}{P_0} + S^R \tag{4-51}$$

The reference state at T_0 and P_0 is arbitrarily selected, and the values assigned to H_0^{ig} and S_0^{ig} are also arbitrary. In practice, only *changes* in H and S are of interest, and fixed reference state values ultimately cancel in their calculation.

The ideal gas state heat capacity C_P^{ig} is a function of T but not of P. For a mixture the heat capacity is simply the molar average $\sum_i y_i C_{P_i}^{ig}$. Empirical equations relating C_P^{ig} to T are available for many pure gases; a common form is

$$\frac{C_P^{ig}}{R} = A + BT + CT^2 + DT^{-2} \tag{4-52}$$

where A, B, C, and D are constants characteristic of the particular gas, and either C or D is zero. The ratio C_P^{ig}/R is dimensionless; thus the units of C_P^{ig} are those of R. Data for ideal gas state heat capacities are given for many substances in Table 2-155.

Evaluation of the integrals $\int C_P^{ig}\,dT$ and $\int (C_P^{ig}/T)\,dT$ is accomplished by substitution for C_P^{ig}, followed by integration. For temperature limits of T_0 and T and with $\tau \equiv T/T_0$, the equations that follow from Eq. (4-52) are

$$\int_{T_0}^{T} \frac{C_P^{ig}}{R}\,dT = AT_0(\tau-1) + \frac{B}{2}T_0^2(\tau^2-1) + \frac{C}{3}T_0^3(\tau^3-1) + \frac{D}{T_0}\left(\frac{\tau-1}{\tau}\right) \tag{4-53}$$

$$\int_{T_0}^{T} \frac{C_P^{ig}}{RT}\,dT = A\ln\tau + \left[BT_0 + \left(CT_0^2 + \frac{D}{\tau^2T_0^2}\right)\left(\frac{\tau+1}{2}\right)\right](\tau-1) \tag{4-54}$$

Equations (4-50) and (4-51) may sometimes be advantageously expressed in alternative form through use of mean heat capacities:

$$H = H_0^{ig} + \langle C_P^{ig} \rangle_H (T - T_0) + H^R \tag{4-55}$$

$$S = S_0^{ig} + \langle C_P^{ig} \rangle_S \ln \frac{T}{T_0} - R \ln \frac{P}{P_0} + S^R \tag{4-56}$$

where $\langle C_P^{ig} \rangle_H$ and $\langle C_P^{ig} \rangle_S$ are mean heat capacities specific, respectively, for enthalpy and entropy calculations. They are given by the following equations:

$$\frac{\langle C_P^{ig} \rangle_H}{R} = A + \frac{B}{2} T_0(\tau + 1) + \frac{C}{3} T_0^2(\tau^2 + \tau + 1) + \frac{D}{\tau T_0^2} \tag{4-57}$$

$$\frac{\langle C_P^{ig} \rangle_S}{R} = A + \left[BT_0 + \left(CT_0^2 + \frac{D}{\tau^2 T_0^2} \right)\left(\frac{\tau + 1}{2} \right) \right] \frac{\tau - 1}{\ln \tau} \tag{4-58}$$

RESIDUAL ENTHALPY AND ENTROPY FROM *PVT* CORRELATIONS

The residual properties of gases and vapors depend on their *PVT* behavior. This is often expressed through correlations for the compressibility factor Z, defined by Eq. (4-36). Analytical expressions for Z as functions of T and P or T and V are known as *equations of state*. They may also be reformulated to give P as a function of T and V or V as a function of T and P.

Virial Equations of State The virial equation in *density* is an infinite series expansion of the compressibility factor Z in powers of molar density ρ (or reciprocal molar volume V^{-1}) about the real gas state at zero density (zero pressure):

$$Z = 1 + B\rho + C\rho^2 + D\rho^3 + \cdots \tag{4-59}$$

The density series virial coefficients $B, C, D, \ldots$ depend on temperature and composition only. In practice, truncation is to two or three terms. The composition dependencies of B and C are given by the exact *mixing rules*

$$B = \sum_i \sum_j y_i y_j B_{ij} \tag{4-60}$$

$$C = \sum_i \sum_j \sum_k y_i y_j y_k C_{ijk} \tag{4-61}$$

where y_i, y_j, and y_k are mole fractions for a gas mixture and i, j, and k identify species.

The coefficient B_{ij} characterizes a bimolecular interaction between molecules i and j, and therefore $B_{ij} = B_{ji}$. Two kinds of second virial coefficient arise: B_{ii} and B_{jj}, wherein the subscripts are the same ($i = j$), and B_{ij}, wherein they are different ($i \neq j$). The first is a virial coefficient for a pure species; the second is a mixture property, called a *cross coefficient*. Similarly for the third virial coefficients: C_{iii}, C_{jjj}, and C_{kkk} are for the pure species, and $C_{iij} = C_{iji} = C_{jii}, \ldots$ are cross coefficients.

Although the virial equation itself is easily rationalized on empirical grounds, the mixing rules of Eqs. (4-60) and (4-61) follow rigorously from the methods of statistical mechanics. The temperature derivatives of B and C are given exactly by

$$\frac{dB}{dT} = \sum_i \sum_j y_i y_j \frac{dB_{ij}}{dT} \tag{4-62}$$

$$\frac{dC}{dT} = \sum_i \sum_j \sum_k y_i y_j y_k \frac{dC_{ijk}}{dT} \tag{4-63}$$

An alternative form of the virial equation expresses Z as an expansion in powers of pressure about the real gas state at zero pressure (zero density):

$$Z = 1 + B'P + C'P^2 + D'P^3 + \cdots \tag{4-64}$$

Equation (4-64) is the virial equation in *pressure*, and $B', C', D', \ldots$ are the pressure series virial coefficients. Again, truncation is to two or three terms, with B' and C' depending on temperature and composition only. Moreover, the two sets of coefficients are related:

$$B' = B/RT \tag{4-65}$$

$$C' = (C - B^2)/(RT)^2 \tag{4-66}$$

Values can often be found for B, but not so often for C. Generalized correlations for both B and C are given by Meng, Duan, and Li [*Fluid Phase Equilibria* **226**: 109–120 (2004)].

For pressures up to several bars, the two-term expansion in pressure, with B' given by Eq. (4-65), is usually preferred:

$$Z = 1 + B'P = 1 + BP/RT \tag{4-67}$$

For supercritical temperatures, it is satisfactory to ever higher pressures as the temperature increases. For pressures above the range where Eq. (4-67) is useful, but below the critical pressure, the virial expansion in density truncated to three terms is usually suitable:

$$Z = 1 + B\rho + C\rho^2 \tag{4-68}$$

Equations for residual enthalpy and entropy may be developed from each of these expressions. Consider first Eq. (4-67), which is explicit in volume. Equations (4-45) and (4-46) are therefore applicable. Direct substitution for Z in Eq. (4-45) gives

$$\frac{G^R}{RT} = \frac{BP}{RT} \tag{4-69}$$

Differentiation of Eq. (4-67) yields

$$\left(\frac{\partial Z}{\partial T} \right)_P = \left(\frac{dB}{dT} - \frac{B}{T} \right) \frac{P}{RT}$$

By Eq. (4-46),

$$\frac{H^R}{RT} = \frac{P}{R} \left(\frac{B}{T} - \frac{dB}{dT} \right) \tag{4-70}$$

and by Eq. (4-47),

$$\frac{S^R}{R} = -\frac{P}{R} \frac{dB}{dT} \tag{4-71}$$

An extensive set of three-parameter corresponding-states correlations has been developed by Pitzer and coworkers [Pitzer, *Thermodynamics*, 3d ed., App. 3, McGraw-Hill, New York (1995)]. Particularly useful is the one for the second virial coefficient. The basic equation is

$$\frac{BP_c}{RT_c} = B^0 + \omega B^1 \tag{4-72}$$

with the *acentric factor* defined by Eq. (2-17). For pure chemical species B^0 and B^1 are functions of reduced temperture only. Substitution for B in Eq. (4-67) by this expression gives

$$Z = 1 + (B^0 + \omega B^1) \frac{P_r}{T_r} \tag{4-73}$$

By differentiation,

$$\left(\frac{\partial Z}{\partial T_r} \right)_{P_r} = P_r \left(\frac{dB^0/dT_r}{T_r} - \frac{B^0}{T_r^2} \right) + \omega P_r \left(\frac{dB^1/dT_r}{T_r} - \frac{B^1}{T_r^2} \right)$$

Upon substitution of these equations into Eqs. (4-48) and (4-49), integration yields

$$\frac{G^R}{RT} = (B^0 + \omega B^1) \frac{P_r}{T_r} \tag{4-74}$$

$$\frac{H^R}{RT_c} = P_r \left[B^0 - T_r \frac{dB^0}{dT_r} + \omega \left(B^1 - T_r \frac{dB^1}{dT_r} \right) \right] \tag{4-75}$$

The residual entropy follows from Eq. (4-47):

$$\frac{S^R}{R} = -P_r \left(\frac{dB^0}{dT_r} + \omega \frac{dB^1}{dT_r} \right) \tag{4-76}$$

In these equations, B^0 and B^1 and their derivatives are well represented by Abbott's correlations [Smith and Van Ness, *Introduction to Chemical Engineering Thermodynamics,* 3d ed., p. 87, McGraw-Hill, New York (1975)]:

$$B^0 = 0.083 - \frac{0.422}{T_r^{1.6}} \tag{4-77}$$

$$B^1 = 0.139 - \frac{0.172}{T_r^{4.2}} \tag{4-78}$$

$$\frac{dB^0}{dT_r} = \frac{0.675}{T_r^{2.6}} \tag{4-79}$$

$$\frac{dB^1}{dT_r} = \frac{0.722}{T_r^{5.2}} \tag{4-80}$$

Although limited to pressures where the two-term virial equation in pressure has approximate validity, these correlations are applicable for most chemical processing conditions. As with all generalized correlations, they are least accurate for polar and associating molecules.

Although developed for pure materials, these correlations can be extended to gas or vapor mixtures. Basic to this extension are the mixing rules for the second virial coefficient and its temperature derivative as given by Eqs. (4-60) and (4-62). Values for the cross coefficients B_{ij}, with $i \neq j$, and their derivatives are provided by Eq. (4-72) written in extended form:

$$B_{ij} = \frac{RT_{cij}}{P_{cij}}(B^0 + \omega_{ij}B^1) \tag{4-81}$$

where B^0, B^1, dB^0/dT_r, and dB^1/dT_r are the same functions of T_r as given by Eqs. (4-77) through (4-80). Differentiation produces

$$\frac{dB_{ij}}{dT} = \frac{RT_{cij}}{P_{cij}}\left(\frac{dB^0}{dT} + \omega_{ij}\frac{dB^1}{dT}\right)$$

$$\frac{dB_{ij}}{dT} = \frac{R}{P_{cij}}\left(\frac{dB^0}{dT_{rij}} + \omega_{ij}\frac{dB^1}{dT_{rij}}\right) \tag{4-82}$$

where $T_{rij} = T/T_{cij}$. The following combining rules for ω_{ij}, T_{cij}, and P_{cij} are given by Prausnitz, Lichtenthaler, and de Azevedo [*Molecular Thermodynamics of Fluid-Phase Equilibria*, 2d ed., pp. 132 and 162, Prentice-Hall, Englewood Cliffs, N.J. (1986)]:

$$\omega_{ij} = \frac{\omega_i + \omega_j}{2} \tag{4-83}$$

$$T_{cij} = (T_{ci}T_{cj})^{1/2}(1 - k_{ij}) \tag{4-84}$$

$$P_{cij} = \frac{Z_{cij}RT_{cij}}{V_{cij}} \tag{4-85}$$

with

$$Z_{cij} = \frac{Z_{ci} + Z_{cj}}{2} \tag{4-86}$$

and

$$V_{cij} = \left(\frac{V_{ci}^{1/3} + V_{cj}^{1/3}}{2}\right)^3 \tag{4-87}$$

In Eq. (4-84), k_{ij} is an empirical interaction parameter specific to an $i-j$ molecular pair. When $i = j$ and for chemically similar species, $k_{ij} = 0$. Otherwise, it is a small (usually) positive number evaluated from minimal *PVT* data or, absence data, set equal to zero.

When $i = j$, all equations reduce to the appropriate values for a pure species. When $i \neq j$, these equations define a set of interaction parameters without physical significance. For a mixture, values of B_{ij} and dB_{ij}/dT from Eqs. (4-81) and (4-82) are substituted into Eqs. (4-60) and (4-62) to provide values of the mixture second virial coefficient B and its temperature derivative. Values of H^R and S^R are then given by Eqs. (4-70) and (4-71).

A primary virtue of Abbott's correlations for second virial coefficients is simplicity. More complex correlations of somewhat wider applicability include those by Tsonopoulos [*AIChE J.* **20:** 263–272 (1974); ibid., **21:** 827–829 (1975); ibid., **24:** 1112–1115 (1978); *Adv. in Chemistry Series 182*, pp. 143–162 (1979)] and Hayden and O'Connell [*Ind. Eng. Chem. Proc. Des. Dev.* **14:** 209–216 (1975)]. For aqueous systems see Bishop and O'Connell [*Ind. Eng. Chem. Res.*, **44:** 630–633 (2005)].

Because Eq. (4-68) is explicit in P, it is incompatible with Eqs. (4-45) and (4-46), and they must be transformed to make V (or molar density ρ) the variable of integration. The resulting equations are given by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 216–217, McGraw-Hill, New York (2005)]:

$$\frac{G^R}{RT} = Z - 1 - \ln Z + \int_0^\rho (Z-1)\frac{d\rho}{\rho} \tag{4-88}$$

$$\frac{H^R}{RT} = Z - 1 - T\int_0^\rho \left(\frac{\partial Z}{\partial T}\right)_\rho \frac{d\rho}{\rho} \tag{4-89}$$

By differentiation of Eq. (4-68),

$$\left(\frac{\partial Z}{\partial T}\right)_\rho = \frac{dB}{dT}\rho + \frac{dC}{dT}\rho^2$$

Substituting in Eqs. (4-88) and (4-89) for Z by Eq. (4-68) and in Eq. (4-89) for the derivative yields, upon integration and reduction,

$$\frac{G^R}{RT} = 2B\rho + \frac{3}{2}C\rho^2 - \ln Z \tag{4-90}$$

$$\frac{H^R}{RT} = \left(B - T\frac{dB}{dT}\right)\rho + \left(C - \frac{T}{2}\frac{dC}{dT}\right)\rho^2 \tag{4-91}$$

The residual entropy is given by Eq. (4-47).

In a process calculation, T and P, rather than T and ρ (or T and V), are usually the favored independent variables. Applications of Eqs. (4-90) and (4-91) therefore require prior solution of Eq. (4-68) for Z or ρ. With $Z = P/\rho RT$, Eq. (4-68) may be written in two equivalent forms:

$$Z^3 - Z^2 - \left(\frac{BP}{RT}\right)Z - \frac{CP^2}{(RT)^2} = 0 \tag{4-92}$$

$$\rho^3 + \left(\frac{B}{C}\right)\rho^2 + \left(\frac{1}{C}\right)\rho - \frac{P}{CRT} = 0 \tag{4-93}$$

In the event that three real roots obtain for these equations, only the largest Z (smallest ρ), appropriate for the vapor phase, has physical significance, because the virial equations are suitable only for vapors and gases.

Data for third virial coefficients are often lacking, but generalized correlations are available. Equation (4-68) may be rewritten in reduced form as

$$Z = 1 + \hat{B}\frac{P_r}{T_rZ} + \hat{C}\left(\frac{P_r}{T_rZ}\right)^2 \tag{4-94}$$

where $\hat{B}$ is the reduced second virial coefficient given by Eq. (4-72). Thus by definition,

$$\hat{B} \equiv \frac{BP_c}{RT_c} = B^0 + \omega B^1 \tag{4-95}$$

The reduced third virial coefficient $\hat{C}$ is defined as

$$\hat{C} \equiv \frac{CP_c^2}{R^2T_c^2} \tag{4-96}$$

A Pitzer-type correlation for $\hat{C}$ is then written as

$$\hat{C} = C^0 + \omega C^1 \tag{4-97}$$

Correlations for C^0 and C^1 with reduced temperature are

$$C^0 = 0.01407 + \frac{0.02432}{T_r} - \frac{0.00313}{T_r^{10.5}} \tag{4-98}$$

$$C^1 = -0.02676 + \frac{0.05539}{T_r^{2.7}} - \frac{0.00242}{T_r^{10.5}} \tag{4-99}$$

The first is given by, and the second is inspired by, Orbey and Vera [*AIChE J.* **29:** 107–113 (1983)].

Equation (4-94) is cubic in Z; with T_r and P_r specified, solution for Z is by iteration. An initial guess of Z = 1 on the right side usually leads to rapid convergence.

Another class of equations, known as *extended* virial equations, was introduced by Benedict, Webb, and Rubin [*J. Chem. Phys.* **8:** 334–345 (1940); **10:** 747–758 (1942)]. This equation contains eight parameters, all functions of composition. It and its modifications, despite their complexity, find application in the petroleum and natural gas industries for light hydrocarbons and a few other commonly encountered gases [see Lee and Kesler, *AIChE J.*, **21:** 510–527 (1975)].

Cubic Equations of State The modern development of cubic equations of state started in 1949 with publication of the Redlich-Kwong (RK) equation [*Chem. Rev.*, **44:** 233–244 (1949)], and many others have since been proposed. An extensive review is given by Valderrama [*Ind. Eng. Chem. Res.* **42:** 1603–1618 (2003)]. Of the equations published more recently, the two most popular are the Soave-Redlich-Kwong (SRK) equation, a modification of the RK equation [*Chem. Eng. Sci.* **27:** 1197–1203 (1972)] and the Peng-Robinson (PR) equation [*Ind. Eng. Chem. Fundam.* **15:** 59–64 (1976)]. All are encompassed by a *generic* cubic equation of state, written as

$$P = \frac{RT}{V-b} - \frac{a(T)}{(V+\epsilon b)(V+\sigma b)} \tag{4-100}$$

For a specific form of this equation, ϵ and σ are pure numbers, the same for all substances, whereas parameters $a(T)$ and b are substance-dependent. Suitable estimates of the parameters in cubic equations of state are usually found from values for the critical constants T_c and P_c. The procedure is discussed by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 93–94, McGraw-Hill, New York (2005)], and for Eq. (4-100) the appropriate equations are given as

$$a(T) = \psi \frac{\alpha(T_r) R^2 T_c^2}{P_c} \tag{4-101}$$

$$b = \Omega \frac{RT_c}{P_c} \tag{4-102}$$

Function $\alpha(T_r)$ is an empirical expression, specific to a particular form of the equation of state. In these equations ψ and Ω are pure numbers, independent of substance and determined for a particular equation of state from the values assigned to ϵ and σ.

As an equation cubic in V, Eq. (4-100) has three volume roots, of which two may be complex. Physically meaningful values of V are always real, positive, and greater than parameter b. When $T > T_c$, solution for V at any positive value of P yields only one real positive root. When $T = T_c$, this is also true, except at the critical pressure, where three roots exist, all equal to V_c. For $T < T_c$, only one real positive (liquidlike) root exists at high pressures, but for a range of lower pressures there are three. Here, the middle root is of no significance; the smallest root is a liquid or liquidlike volume, and the largest root is a vapor or vaporlike volume.

Equation (4-100) may be rearranged to facilitate its solution either for a vapor or vaporlike volume or for a liquid or liquidlike volume.

Vapor:
$$V = \frac{RT}{P} + b - \frac{a(T)}{P} \frac{V-b}{(V+\epsilon b)(V+\sigma b)} \tag{4-103a}$$

Liquid:
$$V = b + (V+\epsilon b)(V+\sigma b)\left[\frac{RT - bP - VP}{a(T)}\right] \tag{4-103b}$$

Solution for V is most convenient with the solve routine of a software package. An initial estimate for V in Eq. (4-103*a*) is the ideal gas value RT/P; for Eq. (4-103*b*) it is $V = b$. In either case, iteration is initiated by substituting the estimate on the right side. The resulting value of V on the left is returned to the right side, and the process continues until the change in V is suitably small.

Equations for Z equivalent to Eqs. (4-103) are obtained by substituting $V = ZRT/P$.

Vapor:
$$Z = 1 + \beta - q\beta \frac{Z - \beta}{(Z+\epsilon\beta)(Z+\sigma\beta)} \tag{4-104a}$$

Liquid:
$$Z = \beta + (Z+\epsilon b)(Z+\sigma b)\left(\frac{1+\beta-Z}{q\beta}\right) \tag{4-104b}$$

where by definition
$$\beta \equiv \frac{bP}{RT} \tag{4-105}$$

and
$$q \equiv \frac{a(T)}{bRT} \tag{4-106}$$

These dimensionless quantities provide simplification, and when combined with Eqs. (4-101) and (4-102), they yield

$$\beta = \Omega \frac{P_r}{T_r} \tag{4-107}$$

$$q = \frac{\Psi\alpha(T_r)}{\Omega T_r} \tag{4-108}$$

In Eq. (4-104*a*) the initial estimate is Z = 1; in Eq. (4-104*b*) it is Z = β. Iteration follows the same pattern as for Eqs. (4-103). The final value of Z yields the volume root through $V = ZRT/P$.

Equations of state, such as the Redlich-Kwong (RK) equation, which expresses Z as a function of T_r and P_r only, yield two-parameter corresponding-states correlations. The SRK equation and the PR equation, in which the acentric factor ω enters through function $\alpha(T_r; \omega)$ as an additional parameter, yield three-parameter corresponding-states correlations. The numerical assignments for parameters ϵ, σ, Ω, and Ψ are given in Table 4-2. Expressions are also given for $\alpha(T_r; \omega)$ for the SRK and PR equations.

As shown by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 218–219, McGraw-Hill, New York (2005)], Eqs. (4-104) in conjunction with Eqs. (4-88), (4-89), and (4-47) lead to

$$\frac{G^R}{RT} = Z - 1 - \ln(Z - \beta) - qI \tag{4-109}$$

$$\frac{H^R}{RT} = Z - 1 + \left[\frac{d \ln \alpha(T_r)}{d \ln T_r} - 1\right] qI \tag{4-110}$$

TABLE 4-2 Parameter Assignments for Cubic Equations of State*

For use with Eqs. (4-104) through (4-106)

Eq. of state	$\alpha(T_r)$	σ	ϵ	Ω	Ψ
RK (1949)	$T_r^{-1/2}$	1	0	0.08664	0.42748
SRK (1972)	$\alpha_{SRK}(T_r; \omega)^{\dagger}$	1	0	0.08664	0.42748
PR (1976)	$\alpha_{PR}(T_r; \omega)^{\ddagger}$	$1+\sqrt{2}$	$1-\sqrt{2}$	0.07780	0.45724

*Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 98, McGraw-Hill, New York (2005).

$^{\dagger}\alpha_{SRK}(T_r; \omega) = [1 + (0.480 + 1.574\omega - 0.176\omega^2)(1 - T_r^{1/2})]^2$

$^{\ddagger}\alpha_{PR}(T_r; \omega) = [1 + (0.37464 + 1.54226\omega - 0.26992\omega^2)(1 - T_r^{1/2})]^2$

$$\frac{S^R}{R} = \ln (Z - \beta) + \frac{d \ln \alpha(T_r)}{d \ln T_r}\; qI \tag{4-111}$$

where
$$I = \frac{1}{\sigma - \epsilon} \ln \left(\frac{Z + \sigma\beta}{Z + \epsilon\beta} \right) \tag{4-112}$$

Preliminary to application of these equations Z is found by solution of either Eq. (4-104*a*) or (4-104*b*).

Cubic equations of state may be applied to mixtures through expressions that give the parameters as functions of composition. No established theory prescribes the form of this dependence, and empirical *mixing rules* are often used to relate mixture parameters to pure-species parameters. The simplest realistic expressions are a linear mixing rule for parameter b and a quadratic mixing rule for parameter a

$$b = \sum_i x_i b_i \tag{4-113}$$

$$a = \sum_i \sum_j x_i x_j a_{ij} \tag{4-114}$$

with $a_{ij} = a_{ji}$. The a_{ij} are of two types: pure-species parameters (like subscripts) and interaction parameters (unlike subscripts). Parameter b_i is for pure species i. The interaction parameter a_{ij} is often evaluated from pure-species parameters by a geometric mean *combining rule*

$$a_{ij} = (a_i a_j)^{1/2} \tag{4-115}$$

These traditional equations yield mixture parameters solely from parameters for the pure constituent species. They are most likely to be satisfactory for mixtures comprised of simple and chemically similar molecules.

Pitzer's Generalized Correlations In addition to the corresponding-states coorelation for the second virial coefficient, Pitzer and coworkers [*Thermodynamics*, 3d ed., App. 3, McGraw-Hill, New York (1995)] developed a full set of generalized correlations. They have as their basis an equation for the compressibility factor, as given by Eq. (2-63):

$$Z = Z^0 + \omega Z^1 \tag{2-63}$$

where Z^0 and Z^1 are each functions of reduced temperature T_r and reduced pressure P_r. Acentric factor ω is defined by Eq. (2-17). Correlations for Z appear in Sec. 2.

Generalized correlations are developed here for the residual enthalpy and residual entropy from Eqs. (4-48) and (4-49). Substitution for Z by Eq. (2-63) puts Eq. (4-48) into generalized form:

$$\frac{G^R}{RT} = \int_0^{P_r} (Z^0 - 1) \frac{dP_r}{P_r} + \omega \int_0^{P_r} Z^1 \frac{dP_r}{P_r} \tag{4-116}$$

Differentiation of Eq. (2-63) yields

$$\left(\frac{\partial Z}{\partial T_r}\right)_{P_r} = \left(\frac{\partial Z^0}{\partial T_r}\right)_{P_r} + \omega \left(\frac{\partial Z^1}{\partial T_r}\right)_{P_r}$$

Substitution for $(\partial Z/\partial T_r)_{P_r}$ in Eq. (4-49) gives

$$\frac{H^R}{RT_c} = -T_r^2 \int_0^{P_r} \left(\frac{\partial Z^0}{\partial T_r}\right)_{P_r} \frac{dP_r}{P_r} - \omega T_r^2 \int_0^{P_r} \left(\frac{\partial Z^1}{\partial T_r}\right)_{P_r} \frac{dP_r}{P_r} \tag{4-117}$$

By Eq. (4-47),
$$\frac{S^R}{R} = \frac{1}{T_r}\left(\frac{H^R}{RT_c}\right) - \frac{G^R}{RT}$$

Combination of Eqs. (4-116) and (4-117) leads to

$$\frac{S^R}{R} = -\int_0^{P_r} \left[T_r \left(\frac{\partial Z^0}{\partial T_r}\right)_{P_r} + Z^0 - 1 \right] \frac{dP_r}{P_r} - \omega \int_0^{P_r} \left[T_r \left(\frac{\partial Z^1}{\partial T_r}\right)_{P_r} + Z^1 \right] \frac{dP_r}{P_r}$$

If the first terms on the right sides of Eq. (4-117) and of this equation (including the minus signs) are represented by $(H^R)^0/RT_c$ and $(S^R)^0/R$ and if the second terms, excluding ω but including the minus signs, are represented by $(H^R)^1/RT_c$ and $(S^R)^1/R$, then

$$\frac{H^R}{RT_c} = \frac{(H^R)^0}{RT_c} + \omega \frac{(H^R)^1}{RT_c} \tag{4-118}$$

$$\frac{S^R}{R} = \frac{(S^R)^0}{R} + \omega \frac{(S^R)^1}{R} \tag{4-119}$$

Pitzer's original correlations for Z and the derived quantities were determined graphically and presented in tabular form. Since then, analytical refinements to the tables have been developed, with extended range and accuracy. The most popular Pitzer-type correlation is that of Lee and Kesler [*AIChE J.* **21:** 510–527 (1975); see also Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 5th, 6th, and 7th eds., App. E, McGraw-Hill, New York (1996, 2001, 2005)]. These tables cover both the liquid and gas phases and span the ranges $0.3 \le T_r \le 4.0$ and $0.01 \le P_r \le 10.0$. They list values of Z^0, Z^1, $(H^R)^0/RT_c$, $(H^R)^1/RT_c$, $(S^R)^0/R$, and $(S^R)^1/R$.

Lee and Kesler also included a Pitzer-type correlation for vapor pressures:

$$\ln P_r^{sat}(T_r) = \ln P_r^0(T_r) + \omega \ln P_r^1(T_r) \tag{4-120}$$

where
$$\ln P_r^0(T_r) = 5.92714 - \frac{6.09648}{T_r} - 1.28862 \ln T_r + 0.169347 T_r^6 \tag{4-121}$$

and
$$\ln P_r^1(T_r) = 15.2518 - \frac{15.6875}{T_r} - 13.4721 \ln T_r + 0.43577 T_r^6 \tag{4-122}$$

The value of ω to be used with Eq. (4-120) is found *from the correlation* by requiring that it reproduce the normal boiling point; that is, ω for a particular substance is determined from

$$\omega = \frac{\ln P_{r_n}^{sat} - \ln P_r^0(T_{r_n})}{\ln P_r^1(T_{r_n})} \tag{4-123}$$

where T_{r_n} is the reduced normal boiling point and $P_{r_n}^{sat}$ is the reduced vapor pressure corresponding to 1 standard atmosphere (1.01325 bar).

Although the tables representing the Pitzer correlations are based on data for pure materials, they may also be used for the calculation of mixture properties. A set of recipes is required relating the parameters T_c, P_c, and ω for a mixture to the pure-species values and to composition. One such set is given by Eqs. (2-80) through (2-82) in the Seventh Edition of *Perry's Chemical Engineers' Handbook* (1997). These equations define *pseudoparameters*, so called because the defined values of T_{pc}, P_{pc}, and ω have no physical significance for the mixture.

The Lee-Kesler correlations provide reliable data for nonpolar and slightly polar gases; errors of less than 3 percent are likely. Larger errors can be expected in applications to highly polar and associating gases.

The quantum gases (e.g., hydrogen, helium, and neon) do not conform to the same corresponding-states behavior as do normal fluids. Prausnitz, Lichtenthaler, and de Azevedo [*Molecular Thermodynamics of Fluid-Phase Equilibria*, 3d ed., pp. 172–173, Prentice-Hall PTR, Upper Saddle River, N.J. (1999)] propose the use of temperature-dependent *effective* critical parameters. For hydrogen, the quantum gas most commonly found in chemical processing, the recommended equations are

$$\frac{T_c}{\text{K}} = \frac{43.6}{1 + 21.8/2.016T} \quad (\text{for } H_2) \tag{4-124}$$

$$\frac{P_c}{\text{bar}} = \frac{20.5}{1 + 44.2/2.016T} \quad (\text{for } H_2) \tag{4-125}$$

$$\frac{V_c}{\text{cm}^3\text{mol}^{-1}} = \frac{51.5}{1 - 9.91/2.016T} \quad (\text{for } H_2) \tag{4-126}$$

where T is absolute temperature in kelvins. Use of these *effective* critical parameters for hydrogen requires the further specification that ω = 0.

OTHER PROPERTY FORMULATIONS

LIQUID PHASE

Although residual properties have formal reality for liquids as well as for gases, their advantageous use as *small* corrections to ideal gas state properties is lost. Calculation of property changes for the liquid state are usually based on alternative forms of Eqs. (4-32) through (4-35), shown in Table 4-1. Useful here are the definitons of two liquid-phase properties—the volume expansivity β and the isothermal compressibility κ:

$$\beta \equiv \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P \tag{4-127}$$

$$\kappa \equiv -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T \tag{4-128}$$

For $V = f(T, P)$, $\quad dV = \left(\frac{\partial V}{\partial T}\right)_P dT + \left(\frac{\partial V}{\partial P}\right)_T dP$

This equation in combination with Eqs. (4-127) and (4-128) becomes

$$\frac{dV}{V} = \beta\, dT - \kappa\, dP \tag{4-129}$$

If V is constant, $\quad \left(\frac{\partial P}{\partial T}\right)_V = \frac{\beta}{\kappa} \quad$ (4-130)

Because liquid-phase isotherms of P versus V are very steep and closely spaced, both β and κ are small. Moreover (outside the critical region), they are weak functions of T and P and are often assumed constant at average values. Integration of Eq. (4-129) then gives

$$\ln\frac{V_2}{V_1} = \beta(T_2 - T_1) - \kappa(P_2 - P_1) \tag{4-131}$$

Substitution for the partial derivatives in Eqs. (4-32) through (4-35) by Eqs. (4-127) and (4-130) yields

$$dH = C_P\, dT + (1 - \beta T)V\, dP \tag{4-132}$$

$$dS = C_P\frac{dT}{T} - \beta V\, dP \tag{4-133}$$

$$dU = C_V\, dT + \left(\frac{\beta}{\kappa}T - P\right)dV \tag{4-134}$$

$$dS = \frac{C_V}{T}dT + \frac{\beta}{\kappa}dV \tag{4-135}$$

Integration of these equations is most common from the saturated-liquid state to the state of compressed liquid at constant T. For example, Eqs. (4-132) and (4-133) in integral form become

$$H = H^{sat} + \int_{P^{sat}}^{P}(1 - \beta T)V\, dP \tag{4-136}$$

$$S = S^{sat} - \int_{P^{sat}}^{P}\beta V\, dP \tag{4-137}$$

Again, β and V are weak functions of pressure for liquids, and are often assumed constant at the values for the saturated liquid at temperature T. An alternative treatment of V comes from Eq, (4-131), which for this application can be written

$$V = V^{sat}\exp[-\kappa(P - P^{sat})]$$

LIQUID/VAPOR PHASE TRANSITION

The isothermal vaporization of a pure liquid results in a phase change from saturated liquid to saturated vapor at vapor pressure P^{sat}. The treatment of this transition is facilitated by definition of property changes of vaporization ΔM^{lv}:

$$\Delta M^{lv} \equiv M^v - M^l \tag{4-138}$$

where M^l and M^v are molar properties for states of saturated liquid and saturated vapor. Some experimental values of the enthalpy change of vaporization ΔH^{lv}, usually called the latent heat of vaporization, are listed in Table 2-150.

The enthalpy change and entropy change of vaporization are directly related:

$$\Delta H^{lv} = T\,\Delta S^{lv} \tag{4-139}$$

This equation follows from Eq. (4-15), because vaporization at the vapor pressure P^{sat} occurs at constant T.

As shown by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 221, McGraw-Hill, New York (2005)] the heat of vaporization is directly related to the slope of the vapor-pressure curve.

$$\Delta H^{lv} = T\,\Delta V^{lv}\frac{dP^{sat}}{dT} \tag{4-140}$$

Known as the Clapeyron equation, this exact thermodynamic relation provides the connection between the properties of the liquid and vapor phases.

In application an empirical vapor pressure versus temperature relation is required. The simplest such equation is

$$\ln P^{sat} = A - \frac{B}{T} \tag{4-141}$$

where A and B are constants for a given chemical species. This equation approximates P^{sat} over its entire temperature range from triple point to critical point. It is also a sound basis for interpolation between reasonably spaced values of T. More satisfactory for general use is the Antoine equation

$$\ln P^{sat} = A - \frac{B}{T + C} \tag{4-142}$$

The Wagner equation is useful for accurate representation of vapor pressure data over a wide temperature range. It expresses the reduced vapor pressure as a function of reduced temperature

$$\ln P_r^{sat} = \frac{A\tau + B\tau^{1.5} + C\tau^3 + D\tau^6}{1 - \tau} \tag{4-143}$$

where $\quad \tau \equiv 1 - T_r$

and A, B, C, and D are constants. Values of the constants for either the Wagner equation or the Antoine equation are given for many species by Poling, Prausnitz, and O'Connell [*The Properties of Gases and Liquids*, 5th ed., App. A, McGraw-Hill, New York (2001)].

Latent heats of vaporization are functions of temperature, and experimental values at a particular temperture are often not available. Recourse is then made to approximate methods. *Trouton's rule* of 1884 provides a simple check on whether values calculated by other methods are reasonable:

$$\frac{\Delta H_n^{lv}}{RT_n} \sim 10$$

Here, T_n is the absolute temperature of the normal boiling point, and ΔH_n^{lv} is the latent heat at this temperature. The units of ΔH_n^{lv}, R, and T_n must be chosen so that $\Delta H_n^{lv}/RT_n$ is dimensionless.

A much more accurate equation is that of Riedel [*Chem. Ing. Tech.* **26:** 679–683 (1954)]:

$$\frac{\Delta H_n^{lv}}{RT_n} = \frac{1.092(\ln P_c - 1.013)}{0.930 - T_{r_n}} \tag{4-144}$$

where P_c is the critical pressure in bars and T_{r_n} is the reduced temperature at T_n. This equation provides reasonable approximations; errors rarely exceed 5 percent.

Estimates of the latent heat of vaporization of a pure liquid at any temperature from the known value at a single temperature may be based on an experimental value or on a value estimated by Eq. (4-144). Watson's equation [*Ind. Eng. Chem.* **35:** 398–406 (1943)] has found wide acceptance:

$$\frac{\Delta H_2^{lv}}{\Delta H_1^{lv}} = \left(\frac{1 - T_{r_2}}{1 - T_{r_1}}\right)^{0.38} \tag{4-145}$$

This equation is simple and fairly accurate.

THERMODYNAMICS OF FLOW PROCESSES

The thermodynamics of flow encompasses mass, energy, and entropy balances for open systems, i.e., for systems whose boundaries allow the inflow and outflow of fluids. The common measures of flow are as follows:

Mass flow rate $\dot{m}$ molar flow rate $\dot{n}$ volumetric flow rate q velocity u

Also $\dot{m} = M\dot{n}$ and $q = uA$

where M is molar mass. Mass flow rate is related to velocity by

$$\dot{m} = uA\rho \tag{4-146}$$

where A is the cross-sectional area of a conduit and ρ is mass density. If ρ is molar density, then this equation yields molar flow rate. Flow rates $\dot{m}$, $\dot{n}$, and q measure quantity per unit of time. Although velocity u does not represent quantity of flow, it is an important design parameter.

MASS, ENERGY, AND ENTROPY BALANCES FOR OPEN SYSTEMS

Mass and energy balances for an open system are written with respect to a region of space known as a *control volume*, bounded by an imaginary *control surface* that separates it from the surroundings. This surface may follow fixed walls or be arbitrarily placed; it may be rigid or flexible.

Mass Balance for Open Systems Because mass is conserved, the time rate of change of mass within the control volume equals the net rate of flow of mass into the control volume. The flow is positive when directed into the control volume and negative when directed out. The mass balance is expressed mathematically by

$$\frac{dm_{cv}}{dt} + \Delta(\dot{m})_{fs} = 0 \tag{4-147}$$

The operator Δ signifies the difference between exit and entrance flows, and the subscript fs indicates that the term encompasses all flowing streams. When the mass flow rate $\dot{m}$ is given by Eq. (4-146),

$$\frac{dm_{cv}}{dt} + \Delta(\rho uA)_{fs} = 0 \tag{4-148}$$

This form of the mass balance equation is often called the *continuity equation*. For the special case of *steady-state* flow, the control volume contains a constant mass of fluid, and the first term of Eq. (4-148) is zero.

General Energy Balance Because energy, like mass, is conserved, the time rate of change of energy within the control volume equals the net rate of energy transfer into the control volume. Streams flowing into and out of the control volume have associated with them energy in its internal, potential, and kinetic forms, and all contribute to the energy change of the system. Energy may also flow across the control surface as heat and work. Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 47–48, McGraw-Hill, New York (2005)] show that the general energy balance for flow processes is

$$\frac{d(mU)_{cv}}{dt} + \Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W} \tag{4-149}$$

The work rate $\dot{W}$ may be of several forms. Most commonly there is shaft work $\dot{W}_s$. Work may be associated with expansion or contraction of the control volume, and there may be stirring work. The velocity u in the kinetic energy term is the bulk mean velocity as defined by the equation $u = \dot{m}/\rho A$; z is elevation above a datum level, and g is the local acceleration of gravity.

Energy Balances for Steady-State Flow Processes Flow processes for which the first term of Eq. (4-149) is zero are said to occur at *steady state*. As discussed with respect to the mass balance, this means that the mass of the system within the control volume is constant; it also means that no changes occur with time in the properties of the fluid within the control volume or at its entrances and exits. No expansion of the control volume is possible under these circumstances. The only work of the process is shaft work, and the general energy balance, Eq. (4-149), becomes

$$\Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W}_s \tag{4-150}$$

Entropy Balance for Open Systems An entropy balance differs from an energy balance in a very important way—*entropy is not conserved*. According to the second law, the entropy changes in the system and surroundings as the result of any process must be positive, with a limiting value of zero for a reversible process. Thus, the entropy changes resulting from the process sum not to zero, but to a positive quantity called the *entropy generation* term. The statement of balance, expressed as rates, is therefore

$$\left\{\begin{matrix}\text{Net rate of}\\ \text{change in}\\ \text{entropy of}\\ \text{flowing streams}\end{matrix}\right\} + \left\{\begin{matrix}\text{Time rate of}\\ \text{change of}\\ \text{entropy}\\ \text{in control}\\ \text{volume}\end{matrix}\right\} + \left\{\begin{matrix}\text{Time rate of}\\ \text{change of}\\ \text{entropy in}\\ \text{surroundings}\end{matrix}\right\} = \left\{\begin{matrix}\text{Total rate}\\ \text{of entropy}\\ \text{generation}\end{matrix}\right\}$$

The equivalent *equation of entropy balance* is

$$\Delta(S\dot{m})_{fs} + \frac{d(mS)_{cv}}{dt} + \frac{dS_{surr}^t}{dt} = \dot{S}_G \geq 0 \tag{4-151}$$

where $\dot{S}_G$ is the entropy generation term. In accord with the second law, it must be positive, with zero as a limiting value. This equation is the general *rate* form of the entropy balance, applicable at any instant. The three terms on the left are the net rate of gain in entropy of the flowing streams, the time rate of change of the entropy of the fluid contained within the control volume, and the time rate of change of the entropy of the surroundings.

The entropy change of the surroundings results from heat transfer between system and surroundings. Let $\dot{Q}_j$ represent the heat-transfer rate at a particular location on the control surface associated with a surroundings temperature $T_{\sigma,j}$. In accord with Eq. (4-3), the rate of entropy change in the surroundings as a result of this transfer is $-\dot{Q}_j/T_{\sigma,j}$. The minus sign converts $\dot{Q}_j$, defined with respect to the system, to a heat rate with respect to the surroundings. The third term in Eq. (4-151) is therefore the sum of all such quantities, and Eq. (4-151) can be written

$$\Delta(S\dot{m})_{fs} + \frac{d(mS)_{cv}}{dt} - \sum_j \frac{\dot{Q}_j}{T_{\sigma,j}} = \dot{S}_G \geq 0 \tag{4-152}$$

For any process, the two kinds of irreversibility are (1) those *internal* to the control volume and (2) those resulting from heat transfer across finite temperature differences that may exist between the

TABLE 4-3 Equations of Balance

General equations of balance		Balance equations for steady-flow processes		Balance equations for single-stream steady-flow processes	
$\frac{dm_{cv}}{dt} + \Delta(\dot{m})_{fs} = 0$	(4-147)	$\Delta(\dot{m})_{fs} = 0$	(4-153)	$\dot{m}_1 = \dot{m}_2 = \dot{m}$	(4-154)
$\frac{d(mU)_{cv}}{dt} + \Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W}$	(4-149)	$\Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W}_s$	(4-150)	$\Delta H + \frac{\Delta u^2}{2} + g\,\Delta z = Q + W_s$	(4-155)
$\frac{d(mS)_{cv}}{dt} + \Delta(S\dot{m})_{fs} - \sum_j \frac{\dot{Q}_j}{T_{\sigma,j}} = \dot{S}_G \geq 0$	(4-152)	$\Delta(S\dot{m})_{fs} - \sum_j \frac{\dot{Q}_j}{T_{\sigma,j}} = \dot{S}_G \geq 0$	(4-156)	$\Delta S - \sum_j \frac{Q_j}{T_{\sigma,j}} = S_G \geq 0$	(4-157)

system and surroundings. In the limiting case where $\dot{S}_G = 0$, the process is *completely reversible*, implying that

- The process is internally reversible within the control volume.
- Heat transfer between the control volume and its surroundings is reversible.

Summary of Equations of Balance for Open Systems Only the most general equations of mass, energy, and entropy balance appear in the preceding sections. In each case important applications require less general versions. The most common restricted case is for steady flow processes, wherein the mass and thermodynamic properties of the fluid within the control volume are not time-dependent. A further simplification results when there is but one entrance and one exit to the control volume. In this event, $\dot{m}$ is the same for both streams, and the equations may be divided through by this rate to put them on the basis of a unit amount of fluid flowing through the control volume. Summarized in Table 4-3 are the basic equations of balance and their important restricted forms.

APPLICATIONS TO FLOW PROCESSES

Duct Flow of Compressible Fluids Thermodynamics provides equations interrelating pressure changes, velocity, duct cross-sectional area, enthalpy, entropy, and specific volume within a flowing stream. Considered here is the adiabatic, steady-state, one-dimensional flow of a compressible fluid in the absence of shaft work and changes in potential energy. The appropriate energy balance is Eq. (4-155). With Q, W_s, and Δz all set equal to zero,

$$\Delta H + \frac{\Delta u^2}{2} = 0$$

In differential form, $$dH = -u\,du \qquad (4\text{-}158)$$

The continuity equation given by Eq. (4-148) here becomes $d(\rho uA) = d(uA/V) = 0$, whence

$$\frac{dV}{V} - \frac{du}{u} - \frac{dA}{A} = 0 \qquad (4\text{-}159)$$

Smith, Abbott, and Van Ness [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 255–258, McGraw-Hill, New York (2005)] show that these basic equations in combination with Eq. (4-15) and other property relations yield two very general equations

$$V(1 - \mathbf{M}^2)\frac{dP}{dx} + T\left(1 + \frac{\beta u^2}{C_P}\right)\frac{dS}{dx} - \frac{u^2}{A}\frac{dA}{dx} = 0 \qquad (4\text{-}160)$$

$$u\frac{du}{dx} - T\left(\frac{\beta u^2/C_P + \mathbf{M}^2}{1 - \mathbf{M}^2}\right)\frac{dS}{dx} + \left(\frac{1}{1 - \mathbf{M}^2}\right)\frac{u^2}{A}\frac{dA}{dx} = 0 \qquad (4\text{-}161)$$

Mach number $\mathbf{M}$ is the ratio of the speed of fluid in the duct to the speed of sound in the fluid. The derivatives in these equations are rates of change with length as the fluid passes through a duct. Equation (4-160) relates the pressure derivative, and Eq. (4-161), the velocity derivative, to the entropy and area derivatives. According to the second law, the irreversibilities of fluid friction in adiabatic flow cause an entropy increase in the fluid in the direction of flow. In the limit as the flow approaches reversibility, this increase approaches zero. In general, then, $dS/dx \geq 0$.

Pipe Flow For a pipe of constant cross-sectional area, $dA/dx = 0$, and Eqs. (4-160) and (4-161) reduce to

$$\frac{dp}{dx} = -\frac{T}{V}\left(\frac{1 + \beta u^2/C_P}{1 - \mathbf{M}^2}\right)\frac{ds}{dx} \qquad u\frac{du}{dx} = T\left(\frac{\beta u^2/C_P + \mathbf{M}^2}{1 - \mathbf{M}^2}\right)\frac{ds}{dx}$$

When flow is subsonic, $\mathbf{M}^2 < 1$; all terms on the right in these equations are then positive, and $dP/dx < 0$ and $du/dx > 0$. Pressure therefore decreases and velocity increases in the direction of flow. The velocity increase is, however, limited, because these inequalities would reverse if the velocity were to become supersonic. This is not possible in a pipe of constant cross-sectional area, and the maximum fluid velocity obtainable is the speed of sound, reached at the *exit* of the pipe. Here, dS/dx reaches its limiting value of zero. For a discharge pressure low enough, the flow becomes sonic and lengthening the pipe does not alter this result; the mass rate of flow decreases so that the sonic velocity is still obtained at the outlet of the lengthened pipe.

According to the equations for supersonic pipe flow, pressure increases and velocity decreases in the direction of flow. However, this flow regime is unstable, and a supersonic stream entering a pipe of constant cross section undergoes a compression shock, the result of which is an abrupt and finite increase in pressure and decrease in velocity to a subsonic value.

Nozzles Nozzle flow is quite different from pipe flow. In a properly designed nozzle, its cross-sectional area changes with length in such a way as to make the flow nearly frictionless. The limit is reversible flow, for which the rate of entropy increase is zero. In this event $dS/dx = 0$, and Eqs. (4-160) and (4-161) become

$$\frac{dP}{dx} = \frac{u^2}{VA}\left(\frac{1}{1 - \mathbf{M}^2}\right)\frac{dA}{dx} \qquad \frac{du}{dx} = -\frac{u}{A}\left(\frac{1}{1 - \mathbf{M}^2}\right)\frac{dA}{dx}$$

The characteristics of flow depend on whether the flow is subsonic ($\mathbf{M} < 1$) or supersonic ($\mathbf{M} > 1$). The possibilities are summarized in Table 4-4. Thus, for subsonic flow in a converging nozzle, the velocity increases and the pressure decreases as the cross-sectional area

TABLE 4-4 Nozzle Characteristics

	Subsonic: $\mathbf{M} < 1$		Supersonic: $\mathbf{M} > 1$	
	Converging	Diverging	Converging	Diverging
$\frac{dA}{dx}$	−	+	−	+
$\frac{dP}{dx}$	−	+	+	−
$\frac{du}{dx}$	+	−	−	+

diminishes. The maximum possible fluid velocity is the speed of sound, reached at the exit. A converging subsonic nozzle can therefore deliver a constant flow rate into a region of variable pressure.

Supersonic velocities characterize the diverging section of a properly designed converging/diverging nozzle. Sonic velocity is reached at the throat, where $dA/dx = 0$, and a further increase in velocity and decrease in pressure require a diverging cross-sectional area to accommodate the increasing volume of flow. The pressure at the throat must be low enough for the velocity to become sonic. If this is not the case, the diverging section acts as a diffuser—the pressure rises and the velocity decreases in the conventional behavior of subsonic flow in a diverging section.

An analytical expression relating velocity to pressure in an isentropic nozzle is readily derived for an ideal gas with constant heat capacities. Combination of Eqs. (4-15) and (4-159) for isentropic flow gives

$$u\,du = -V\,dP$$

Integration, with nozzle entrance and exit conditions denoted by 1 and 2, yields

$$u_2^2 - u_1^2 = -2\int_{P_1}^{P_2} V\,dP = \frac{2\gamma P_1 V_1}{\gamma - 1}\left[1 - \left(\frac{P_2}{P_1}\right)^{(\gamma-1)/\gamma}\right] \qquad (4\text{-}162)$$

where the final term is obtained upon elimination of V by $PV^\gamma = \text{const}$, an equation valid for ideal gases with constant heat capacities. Here, $\gamma \equiv C_P/C_V$.

Throttling Process Fluid flowing through a restriction, such as an orifice, without appreciable change in kinetic or potential energy undergoes a finite pressure drop. This *throttling process* produces no shaft work, and in the absence of heat transfer, Eq. (4-155) reduces to $\Delta H = 0$ or $H_2 = H_1$. The process therefore occurs at constant enthalpy.

The temperature of an ideal gas is not changed by a throttling process, because its enthalpy depends on temperature only. For most real gases at moderate conditions of T and P, a reduction in pressure at constant enthalpy results in a decrease in temperature, although the effect is usually small. Throttling of a wet vapor to a sufficiently low pressure causes the liquid to evaporate and the vapor to become superheated. This results in a considerable temperature drop because of the evaporation of liquid.

If a saturated liquid is throttled to a lower pressure, some of the liquid vaporizes or *flashes*, producing a mixture of saturated liquid and saturated vapor at the lower pressure. Again, the large temperature drop results from evaporation of liquid.

Turbines (Expanders) High-velocity streams from nozzles impinging on blades attached to a rotating shaft form a turbine (or expander) through which vapor or gas flows in a steady-state expansion process which converts internal energy of a high-pressure stream into shaft work. The motive force may be provided by steam (turbine) or by a high-pressure gas (expander).

In any properly designed turbine, heat transfer and changes in potential and kinetic energy are negligible. Equation (4-155) therefore reduces to

$$W_s = \Delta H = H_2 - H_1 \qquad (4\text{-}163)$$

The rate form of this equation is

$$\dot{W}_s = \dot{m}\,\Delta H = \dot{m}(H_2 - H_1) \qquad (4\text{-}164)$$

When inlet conditions T_1 and P_1 and discharge pressure P_2 are known, the value of H_1 is fixed. In Eq. (4-163) both H_2 and W_s are unknown, and the energy balance alone does not allow their calculation. However, if the fluid expands *reversibly and adiabatically*, i.e., isentropically, in the turbine, then $S_2 = S_1$. This second equation establishes the final state of the fluid and allows calculation of H_2. Equation (4-164) then gives the isentropic work:

$$W_s(\text{isentropic}) = (\Delta H)_S \qquad (4\text{-}165)$$

The absolute value $|W_s|$(isentropic) is the *maximum* work that can be produced by an adiabatic turbine with given inlet conditions and given

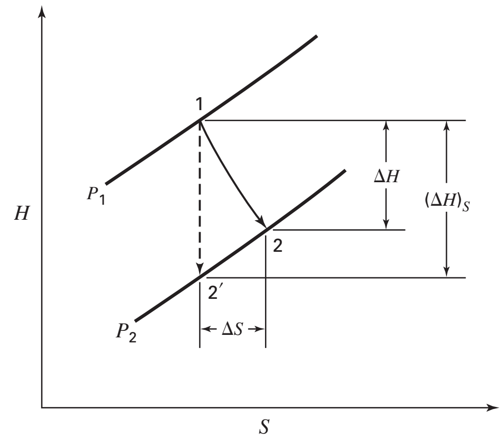

FIG. 4-2 Adiabatic expansion process in a turbine or expander. [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 269, McGraw-Hill, New York (2005).*]

discharge pressure. Because the actual expansion process is irreversible, *turbine efficiency* is defined as

$$\eta \equiv \frac{W_s}{W_s(\text{isentropic})}$$

where W_s is the actual shaft work. By Eqs. (4-163) and (4-165),

$$\eta = \frac{\Delta H}{(\Delta H)_S} \qquad (4\text{-}166)$$

Values of η usually range from 0.7 to 0.8.

The *HS* diagram of Fig. 4-2 compares the path of an actual expansion in a turbine with that of an isentropic expansion for the same intake conditions and the same discharge pressure. The isentropic path is the dashed vertical line from point 1 at intake pressure P_1 to point 2′ at P_2. The irreversible path (solid line) starts at point 1 and terminates at point 2 on the isobar for P_2. The process is adiabatic, and irreversibilities cause the path to be directed toward increasing entropy. The greater the irreversiblity, the farther point 2 lies to the right on the P_2 isobar, and the lower the value of η.

Compression Processes Compressors, pumps, fans, blowers, and vacuum pumps are all devices designed to bring about pressure increases. Their energy requirements for steady-state operation are of interest here. Compression of gases may be accomplished in rotating equipment (high-volume flow) or for high pressures in cylinders with reciprocating pistons. The energy equations are the same; indeed, based on the same assumptions, they are the same as for turbines or expanders. Thus, Eqs. (4-159) through (4-161) apply to adiabatic compression.

The isentropic work of compression, as given by Eq. (4-165), is the *minimum* shaft work required for compression of a gas from a given initial state to a given discharge pressure. A compressor efficiency is defined as

$$\eta \equiv \frac{W_s(\text{isentropic})}{W_s}$$

In view of Eqs. (4-163) and (4-165), this becomes

$$\eta \equiv \frac{(\Delta H)_S}{\Delta H} \qquad (4\text{-}167)$$

Compressor efficiencies are usually in the range of 0.7 to 0.8.

The compression process is shown on an *HS* diagram in Fig. 4-3. The vertical dashed line rising from point 1 to point 2′ represents the reversible adiabatic (isentropic) compression process from P_1 to P_2.

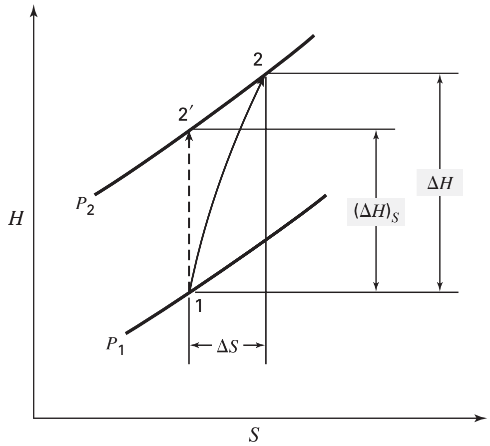

FIG. 4-3 Adiabatic compression process. [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 274, McGraw-Hill, New York (2005).*]

The actual irreversible compression process follows the solid line from point 1 upward and to the right in the direction of increasing entropy, terminating at point 2. The more irreversible the process, the farther this point lies to the right on the P_2 isobar, and the lower the efficiency η of the process.

Liquids are moved by pumps, usually by rotating equipment. The same equations apply to adiabatic pumps as to adiabatic compressors. Thus, Eqs. (4-163) through (4-165) and Eq. (4-167) are valid. However, application of Eq. (4-163) requires values of the enthalpy of compressed (subcooled) liquids, and these are seldom available. The fundamental property relation, Eq. (4-15), provides an alternative. For an isentropic process,

$$dH = V\,dP \qquad \text{(constant } S)$$

Combining this with Eq. (4-165) yields

$$W_s(\text{isentropic}) = (\Delta H)_S = \int_{P_1}^{P_2} V\,dP$$

The usual assumption for liquids (at conditions well removed from the critical point) is that V is independent of P. Integration then gives

$$W_s(\text{isentropic}) = (\Delta H)_S = V(P_2 - P_1) \tag{4-168}$$

Also useful are Eqs. (4-132) and (4-133). Because temperature changes in the pumped fluid are very small and because the properties of liquids are insensitive to pressure (again at conditions not close to the critical point), these equations are usually integrated on the assumption that C_P, V, and β are constant, usually at initial values. Thus, to a good approximation

$$\Delta H = C_P\,\Delta T + V(1 - \beta T)\,\Delta P \tag{4-169}$$

$$\Delta S = C_P \ln \frac{T_2}{T_1} - \beta V\,\Delta P \tag{4-170}$$

Example 1: LNG Vaporization and Compression A port facility for unloading liquefied natural gas (LNG) is under consideration. The LNG arrives by ship, stored as saturated liquid at 115 K and 1.325 bar, and is unloaded at the rate of 450 kg s^{-1}. It is proposed to vaporize the LNG with heat discarded from a heat engine operating between 300 K, the temperature of atmospheric air, and 115 K, the temperature of the vaporizing LNG. The saturated-vapor LNG so produced is compressed adiabatically to 20 bar, using the work produced by the heat engine to supply part of the compression work. Estimate the work to be supplied from an external source.

For estimation purposes we need not be concerned with the design of the heat engine, but assume that a suitable engine can be built to deliver 30 percent of the work of a Carnot engine operating between the temperatures of 300 and 115 K. The equations that apply to Carnot engines can be found in any thermodynamics text.

By the first law: $\quad |W| = |Q_H| - |Q_C|$

By the second law: $\quad \dfrac{|Q_H|}{|Q_C|} = \dfrac{T_H}{T_C}$

In combination: $\quad |W| = |Q_C|\left(\dfrac{T_H}{T_C} - 1\right)$

Here, $|W|$ is the work produced by the Carnot engine; $|Q_C|$ is the heat transferred at the cold temperature, i.e., to vaporize the LNG; T_H and T_C are the hot and cold temperatures of the heat reservoirs between which the heat engine operates, or 300 and 115 K, respectively. LNG is essentially pure methane, and enthalpy values from Table 2-281 of the Seventh Edition of *Perry's Chemical Engineers' Handbook* provide its heat of vaporization:

$$\Delta H^{lv} = H^v - H^l = 802.5 - 297.7 = 504.8 \text{ kJ kg}^{-1}$$

For a flow rate of 450 kg s^{-1},

$$|Q_C| = (450)(504.8) = 227{,}160 \text{ kJ s}^{-1}$$

The equation for work gives

$$|W| = (227{,}160)\left(\frac{300}{115} - 1\right) = 3.654 \times 10^5 \text{ kJ s}^{-1} = 3.654 \times 10^5 \text{ kW}$$

This is the reversible work of a Carnot engine. The assumption is that the actual power produced is 30 percent of this, or 1.096×10^5 kW.

The enthalpy and entropy of saturated vapor at 115 K and 1.325 bar are given in Table 2-281 of the Seventh Edition of *Perry's* as

$$H^v = 802.5 \text{ kJ kg}^{-1} \qquad \text{and} \qquad S^v = 9.436 \text{ kJ kg}^{-1}\text{ K}^{-1}$$

Isentropic compression of saturated vapor at 1.325 to 20 bar produces superheated vapor with an entropy of 9.436 kJ kg^{-1} K^{-1}. Interpolation in Table 2-282 at 20 bar yields an enthalpy of H = 1026.2 kJ kg^{-1} at 234.65 K. The enthalpy change of isentropic compression is then

$$\Delta H_S = 1026.2 - 802.5 = 223.7 \text{ kJ kg}^{-1}$$

For a compressor efficiency of 75 percent, the actual enthalpy change of compression is

$$\Delta H = \frac{\Delta H_S}{\eta} = \frac{223.7}{0.75} = 298.3 \text{ kJ kg}^{-1}$$

The actual enthalpy of superheated LNG at 20 bar is then

$$H = 802.5 + 298.3 = 1100.8 \text{ kJ kg}^{-1}$$

Interpolation in Table 2-282 of the Seventh Edition of *Perry's* indicates an actual temperature of 265.9 K for the compressed LNG, which is quite suitable for its entry into the distribution system.

The work of compression is

$$|W| = m\,\Delta H = (450 \text{ kg s}^{-1})(298.3 \text{ kJ kg}^{-1}) = 1.342 \times 10^5 \text{ kJ s}^{-1} = 1.342 \times 10^5 \text{ kW}$$

The estimated power which must be supplied from an external source is

$$\dot{W} = 1.342 \times 10^5 - 1.096 \times 10^5 = 24{,}600 \text{ kW}$$

SYSTEMS OF VARIABLE COMPOSITION

The composition of a system may vary because the system is open or because of chemical reactions even in a closed system. The equations developed here apply regardless of the cause of composition changes.

PARTIAL MOLAR PROPERTIES

For a homogeneous PVT system comprised of any number of chemical species, let symbol M represent the molar (or unit-mass) value of an extensive thermodynamic property, say, U, H, S, A, or G. A total-system property is then nM, where $n = \Sigma_i n_i$ and i is the index identifying chemical species. One might expect the solution property M to be related solely to the properties M_i of the pure chemical species which comprise the solution. However, no such generally valid relation is known, and the connection must be established experimentally for every specific system.

Although the chemical species which make up a solution do not have their own individual properties, a solution property may be arbitrarily

apportioned among the individual species. Once an apportioning recipe is adopted, the assigned property values are quite logically treated as though they were indeed properties of the individual species in solution, and reasoning on this basis leads to valid conclusions.

For a homogeneous *PVT* system, postulate 5 requires that

$$nM = \mathcal{M}(T, P, n_1, n_2, n_3, \ldots)$$

The total differential of nM is therefore

$$d(nM) = \left[\frac{\partial(nM)}{\partial T}\right]_{P,n} dT + \left[\frac{\partial(nM)}{\partial P}\right]_{T,n} dP + \sum_i \left[\frac{\partial(nM)}{\partial n_i}\right]_{T,P,n_j} dn_i$$

where subscript n indicates that all mole numbers n_i are held constant, and subscript n_j signifies that all mole numbers are held constant except the ith. This equation may also be written

$$d(nM) = n\left(\frac{\partial M}{\partial T}\right)_{P,x} dT + n\left(\frac{\partial M}{\partial P}\right)_{T,x} dP + \sum_i \left[\frac{\partial(nM)}{\partial n_i}\right]_{T,P,n_j} dn_i$$

where subscript x indicates that all mole fractions are held constant. The derivatives in the summation are called *partial molar properties*. They are given the generic symbol $\overline{M}_i$ and are defined by

$$\overline{M}_i \equiv \left[\frac{\partial(nM)}{\partial n_i}\right]_{T,P,n_j} \tag{4-171}$$

The basis for calculation of partial properties from solution properties is provided by this equation. Moreover,

$$d(nM) = n\left(\frac{\partial M}{\partial T}\right)_{P,x} dT + n\left(\frac{\partial M}{\partial P}\right)_{T,x} dP + \sum_i \overline{M}_i\, dn_i \tag{4-172}$$

This equation, valid for any equilibrium phase, either closed or open, attributes changes in total property nM to changes in T and P and to mole-number changes resulting from mass transfer or chemical reaction.

The following are mathematical identities:

$$d(nM) = n\, dM + M\, dn \qquad dn_i = d(x_i n) = x_i\, dn + n\, dx_i$$

Combining these expressions with Eq. (4-172) and collecting like terms give

$$\left[dM - \left(\frac{\partial M}{\partial T}\right)_{P,x} dT - \left(\frac{\partial M}{\partial P}\right)_{T,x} dP - \sum_i \overline{M}_i\, dx_i\right] n + \left[M - \sum_i \overline{M}_i x_i\right] dn = 0$$

Because n and dn are independent and arbitrary, the terms in brackets must separately be zero, whence

$$dM = \left(\frac{\partial M}{\partial T}\right)_{P,x} dT + \left(\frac{\partial M}{\partial P}\right)_{T,x} dP + \sum_i \overline{M}_i\, dx_i \tag{4-173}$$

and

$$M = \sum_i x_i \overline{M}_i \tag{4-174}$$

The first of these equations is merely a special case of Eq. (4-172); however, Eq. (4-174) is a vital new relation. Known as the *summability equation*, it provides for the calculation of solution properties from partial properties, a purpose opposite to that of Eq. (4-171). Thus a solution property apportioned according to the recipe of Eq. (4-171) may be recovered simply by adding the properties attributed to the individual species, each weighted by its mole fraction in solution. The equations for partial molar properties are valid also for partial specific properties, in which case m replaces n and $\{x_i\}$ are mass fractions. Equation (4-171) applied to the definitions of Eqs. (4-8) through (4-10) yields the partial-property relations

$$\overline{H}_i = \overline{U}_i + P\overline{V}_i \qquad \overline{A}_i = \overline{U}_i - T\overline{S}_i \qquad \overline{G}_i = \overline{H}_i - T\overline{S}_i$$

These equations illustrate the parallelism that exists between the equations for a constant-composition solution and those for the corresponding partial properties. This parallelism exists whenever the solution properties in the parent equation are related linearly (in the algebraic sense).

Gibbs-Duhem Equation Differentiation of Eq. (4-174) yields

$$dM = \sum_i x_i\, d\overline{M}_i + \sum_i \overline{M}_i\, dx_i$$

Because this equation and Eq. (4-173) are both valid in general, their right sides can be equated, yielding

$$\left(\frac{\partial M}{\partial T}\right)_{P,x} dT + \left(\frac{\partial M}{\partial P}\right)_{T,x} dP - \sum_i x_i\, d\overline{M}_i = 0 \tag{4-175}$$

This general result, the Gibbs-Duhem equation, imposes a constraint on how the partial properties of any phase may vary with temperature, pressure, and composition. For the special case where T and P are constant,

$$\sum_i x_i\, d\overline{M}_i = 0 \qquad \text{(constant } T, P) \tag{4-176}$$

Symbol M may represent the molar value of any extensive thermodynamic property, say, V, U, H, S, or G. When $M \equiv H$, the derivatives $(\partial H/\partial H)_P$ and $(\partial H/\partial P)_T$ are given by Eqs. (4-28) and (4-29), and Eqs. (4-173), (4-174), and (4-175) specialize to

$$dH = C_P\, dT + \left[V - T\left(\frac{\partial V}{\partial T}\right)_{P,x}\right] dP + \sum_i \overline{H}_i\, dx_i \tag{4-177}$$

$$H = \sum_i x_i \overline{H}_i \tag{4-178}$$

$$C_P dT + \left[V - T\left(\frac{\partial V}{\partial T}\right)_{P,x}\right] dP - \sum_i x_i\, d\overline{H}_i = 0 \tag{4-179}$$

Similar equations are readily derived when M takes on other identities.

Equation (4-171), which defines a partial molar property, provides a general means by which partial-property values may be determined. However, for a *binary* solution an alternative method is useful. Equation (4-174) for a binary solution is

$$M = x_1\overline{M}_1 + x_2\overline{M}_2$$

Moreover, the Gibbs-Duhem equation for a solution at given T and P, Eq. (4-176), becomes

$$x_1\, d\overline{M}_1 + x_2\, d\overline{M}_2 = 0$$

These two equations combine to yield

$$\overline{M}_1 = M + x_2 \frac{dM}{dx_1} \tag{4-180a}$$

$$\overline{M}_2 = M - x_1 \frac{dM}{dx_1} \tag{4-180b}$$

Thus for a binary solution, the partial properties are given directly as functions of composition for given T and P. For multicomponent solutions such calculations are complex, and direct use of Eq. (4-171) is appropriate.

Partial Molar Equation-of-State Parameters The parameters in equations of state as applied to mixtures are related to composition by mixing rules. For the second virial coefficient

$$B = \sum_i \sum_j y_i y_j B_{ij} \tag{4-60}$$

The partial molar second virial coefficient is by definition

$$\overline{B}_i \equiv \left[\frac{\partial(nB)}{\partial n_i}\right]_{T,n_j} \tag{4-181}$$

Because B is independent of P, this is in accord with Eq. (4-171). These two equations lead through derivation to useful expressions for $\overline{B}_i$, as shown in detail by Van Ness and Abbott [*Classical Thermodynamics of Nonelectrolyte Solutions: With Applications to Phase*

Equilibria, pp. 137–140, McGraw-Hill, New York (1982)]. The simplest result is

$$\bar{B}_i = 2\sum_k y_k B_{ki} - B \tag{4-182}$$

An analogous expression follows from Eq. (4-114) for parameter a in the generic cubic equation of state given by Eqs. (4-100), (4-103), and (4-104):

$$\bar{a}_i = 2\sum_k y_k a_{ki} - a \tag{4-183}$$

This expression is independent of the combining rule [e.g., Eq. (4-114)] used for a_{ki}. For the *linear* mixing rule of Eq. (4-113) for b, the result of derivation is simply $\bar{b}_i = b_i$.

Partial Molar Gibbs Energy Implicit in Eq. (4-13) is the relation

$$\mu_i = \left[\frac{\partial(nG)}{\partial n_i}\right]_{T,P,n_j}$$

Comparison with Eq. (4-171) indicates the following identity:

$$\mu_i = \bar{G}_i \tag{4-184}$$

The reciprocity relation for an exact differential applied to Eq. (4-13) produces not only the Maxwell relation, Eq. (4-21), but also two other useful equations:

$$\left(\frac{\partial \mu_i}{\partial P}\right)_{T,n} = \left[\frac{\partial(nV)}{\partial n_i}\right]_{T,P,n_j} = \bar{V}_i \tag{4-185}$$

$$\left(\frac{\partial \mu_i}{\partial T}\right)_{P,n} = -\left[\frac{\partial(nS)}{\partial n_i}\right]_{T,P,n_j} = -\bar{S}_i \tag{4-186}$$

Because $\mu = f(T, P)$,

$$d\mu_i \equiv d\bar{G}_i = \left(\frac{\partial \mu_i}{\partial T}\right)_{P,n} dT + \left(\frac{\partial \mu_i}{\partial P}\right)_{T,n} dP$$

and

$$d\bar{G}_i = -\bar{S}_i\, dT + \bar{V}_i\, dP \tag{4-187}$$

Similarly, in view of Eqs. (4-14), (4-15), and (4-16),

$$d\bar{U}_i = T\, d\bar{S}_i - P\, d\bar{V}_i \tag{4-188}$$

$$d\bar{H}_i = T\, d\bar{S}_i + \bar{V}_i\, dP \tag{4-189}$$

$$d\bar{A}_i = -\bar{S}_i\, dT - P\, d\bar{V}_i \tag{4-190}$$

These equations again illustrate the fact that for every equation providing a *linear* relation among the thermodynamic properties of a *constant-composition* solution there exists a parallel relationship for the partial properties of the species in solution.

The following equation is a mathematical identity:

$$d\left(\frac{nG}{RT}\right) \equiv \frac{1}{RT}\, d(nG) - \frac{nG}{RT^2}\, dT$$

Substitution for $d(nG)$ by Eq. (4-13), with $\mu_i = \bar{G}_i$, and for G by Eq. (4-10) gives, after algebraic reduction,

$$d\left(\frac{nG}{RT}\right) = \frac{nV}{RT}\, dP - \frac{nH}{RT^2}\, dT + \sum_i \frac{\bar{G}_i}{RT}\, dn_i \tag{4-191}$$

This result is a useful alternative to the fundamental property relation given by Eq. (4-13). All terms in this equation have units of moles; moreover, the enthalpy rather than the entropy appears on the right side.

SOLUTION THERMODYNAMICS

Ideal Gas Mixture Model The ideal gas mixture model is useful because it is molecularly based, is analytically simple, is realistic in the limit of zero pressure, and provides a conceptual basis upon which to build the structure of solution thermodynamics. Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 391–394, McGraw-Hill, New York (2005)] develop the following property relations for the ideal gas model.

$$\bar{V}_i^{ig} = V_i^{ig} = \frac{RT}{P} \tag{4-192}$$

Because the enthalpy is independent of pressure,

$$\bar{H}_i^{ig} = H_i^{ig} \tag{4-193}$$

where S_i^{ig} is evaluated at the *mixture* T and P. The entropy of an ideal gas *does* depend on pressure, and here

$$\bar{S}_i^{ig} = S_i^{ig} - R \ln y_i \tag{4-194}$$

where S_i^{ig} is evaluated at the mixture T and P.

From the definition of the Gibbs energy, $\bar{G}_i^{ig} = \bar{H}_i^{ig} - T\bar{S}_i^{ig}$. In combination with Eqs. (4-193) and (4-194), this becomes

$$\bar{G}_i^{ig} = H_i^{ig} - TS_i^{ig} + RT \ln y_i$$

or

$$\mu_i^{ig} \equiv \bar{G}_i^{ig} = G_i^{ig} + RT \ln y_i \tag{4-195}$$

Elimination of G_i^{ig} from this equation is accomplished through Eq. (4-17), written for pure species i as an ideal gas:

$$dG_i^{ig} = V_i^{ig}\, dP = \frac{RT}{P}\, dP = RT\, d \ln P \qquad \text{(constant } T\text{)}$$

Integration gives

$$G_i^{ig} = \Gamma_i(T) + RT \ln P \tag{4-196}$$

where integration constant $\Gamma_i(T)$ is a function of temperature only. Equation (4-195) now becomes

$$\mu_i^{ig} = \bar{G}_i^{ig} = \Gamma_i(T) + RT \ln (y_i P) \tag{4-197}$$

By Eq. (4-172)

$$G^{id} = \sum_i y_i \Gamma_i(T) + RT \sum_i \ln (y_i P) \tag{4-198}$$

A dimensional ambiguity is apparent with Eqs. (4-196) through (4-198) in that P has units, whereas $\ln P$ must be dimensionless. In practice this is of no consequence, because only *differences* in Gibbs energy appear, along with *ratios* of the quantities with units of pressure in the arguments of the logarithm. Consistency in the units of pressure is, of course, required.

Fugacity and Fugacity Coefficient The chemical potential μ_i plays a vital role in both phase and chemical reaction equilibria. However, the chemical potential exhibits certain unfortunate characteristics that discourage its use in the solution of practical problems. The Gibbs energy, and hence μ_i, is defined in relation to the internal energy and entropy, both primitive quantities for which absolute values are unknown. Moreover, μ_i approaches negative infinity when either P or y_i approaches zero. While these characteristics do not preclude the use of chemical potentials, the application of equilibrium criteria is facilitated by introduction of the *fugacity*, a quantity that takes the place of μ_i but that does not exhibit its less desirable characteristics.

The origin of the fugacity concept resides in Eq. (4-196), an equation valid only for pure species i in the ideal gas state. For a *real* fluid, an analogous equation is written as

$$G_i \equiv \Gamma_i(T) + RT \ln f_i \tag{4-199}$$

in which a new property f_i replaces the pressure P. This equation serves as a partial definition of the *fugacity* f_i.

Subtraction of Eq. (4-196) from Eq. (4-199), both written for the same temperature and pressure, gives

$$G_i - G_i^{ig} = RT \ln \frac{f_i}{P}$$

According to the definition of Eq. (4-40), $G_i - G_i^{ig}$ is the residual Gibbs energy G_i^R. The dimensionless ratio f_i/P is another new property called the *fugacity coefficient* ϕ_i. Thus,

$$G_i^R = RT \ln \phi_i \tag{4-200}$$

where
$$\phi_i \equiv \frac{f_i}{P} \tag{4-201}$$

The definition of fugacity is completed by setting the ideal gas state fugacity of pure species i equal to its pressure, $f_i^{ig} = P$. Thus for the special case of an ideal gas, $G_i^R = 0$, $\phi_i = 1$, and Eq. (4-196) is recovered from Eq. (4-199).

The definition of the fugacity of a species in solution is parallel to the definition of the pure-species fugacity. An equation analogous to the ideal gas expression, Eq. (4-197), is written for species i in a fluid mixture

$$\mu_i \equiv \Gamma_i(T) + RT \ln \hat{f}_i \tag{4-202}$$

where the partial pressure y_iP is replaced by $\hat{f}_i$, the fugacity of species i in solution. Because it is not a partial property, it is identified by a circumflex rather than an overbar.

Subtracting Eq. (4-197) from Eq. (4-202), both written for the same temperature, pressure, and composition, yields

$$\mu_i - \mu_i^{ig} = RT \ln \frac{\hat{f}_i}{y_iP}$$

The residual Gibbs energy of a mixture is defined by $G^R \equiv G - G^{ig}$, and the analogous definition of a partial molar residual Gibbs energy is $\bar{G}_i^R \equiv \bar{G}_i - \bar{G}_i^{ig} = \mu_i - \mu_i^{ig}$. Therefore

$$\bar{G}_i^R = RT \ln \hat{\phi}_i \tag{4-203}$$

where by definition
$$\hat{\phi}_i \equiv \frac{\hat{f}_i}{y_iP} \tag{4-204}$$

The dimensionless ratio $\hat{\phi}_i$ is called the *fugacity coefficient of species i in solution*.

Equation (4-203) is the analog of Eq. (4-200), which relates ϕ_i to G_i^R. For an ideal gas, $\bar{G}_i^R$ is necessarily zero; therefore $\hat{\phi}_i^{ig} = 1$ and $\hat{f}_i^{ig} = y_iP$. Thus the fugacity of species i in an ideal gas mixture is equal to its partial pressure.

Evaluation of Fugacity Coefficients Combining Eq. (4-200) with Eq. (4-45) gives

$$\ln \phi = \frac{G^R}{RT} = \int_0^P (Z-1)\frac{dP}{P} \tag{4-205}$$

Subscript i is omitted, with the understanding that ϕ here is for a pure species. Clearly, all correlations for G^R/RT are also correlations for $\ln \phi$.

Equation (4-200) with Eqs. (4-48) and (4-73) yields

$$\ln \phi = \int_0^{P_r} (Z-1)\frac{dP_r}{P_r} = (B^0 + \omega B^1)\frac{P_r}{T_r} \tag{4-206}$$

This equation, used in conjunction with Eqs. (4-77) and (4-78), provides a useful generalized correlation for the fugacity coefficients of pure species.

A more comprehensive generalized correlation results from Eqs. (4-200) and (4-116):

$$\ln \phi = \int_0^{P_r} (Z^0-1)\frac{dP_r}{P_r} + \omega \int_0^{P_r} Z^1 \frac{dP_r}{P_r}$$

An alternative form is
$$\ln \phi = \ln \phi^0 + \omega \ln \phi^1 \tag{4-207}$$

where
$$\ln \phi^0 \equiv \int_0^{P_r} (Z^0-1)\frac{dP_r}{P_r} \qquad \text{and} \qquad \ln \phi^1 \equiv \int_0^{P_r} Z^1 \frac{dP_r}{P_r}$$

By Eq. (4-207),
$$\phi = (\phi^0)(\phi^1)^\omega \tag{4-208}$$

Correlations may therefore be presented for ϕ^0 and ϕ^1, as was done by Lee and Kesler [*AIChE J.* **21:** 510–527 (1975)].

Ideal Solution Model The ideal gas model is useful as a standard of comparison for real gas behavior. This is formalized through residual properties. The *ideal solution* is similarly useful as a standard to which real solution behavior may be compared.

The partial molar Gibbs energy or chemical potential of species i in an ideal gas mixture is given by Eq. (4-195), written as

$$\mu_i^{ig} = \bar{G}_i^{ig} = G_i^{ig}(T, P) + RT \ln y_i$$

This equation takes on new meaning when $G_i^{ig}(T, P)$ is replaced by $G_i(T, P)$, the Gibbs energy of pure species i in its *real physical state* of gas, liquid, or solid at the mixture T and P. The ideal solution is therefore *defined* as one for which

$$\mu_i^{id} = \bar{G}_i^{id} \equiv G_i(T, P) + RT \ln x_i \tag{4-209}$$

where superscript *id* denotes an ideal solution property and x_i represents the mole fraction because application is usually to liquids.

This equation is the basis for development of expressions for all other thermodynamic properties of an ideal solution. Equations (4-185) and (4-186), applied to an ideal solution with μ_i replaced by $\bar{G}_i$, are written as

$$\bar{V}_i^{id} = \left(\frac{\partial \bar{G}_i^{id}}{\partial P}\right)_{T,x} \qquad \text{and} \qquad \bar{S}_i^{id} = -\left(\frac{\partial \bar{G}_i^{id}}{\partial T}\right)_{P,x}$$

Differentiation of Eq. (4-209) yields

$$\left(\frac{\partial \bar{G}_i^{id}}{\partial P}\right)_{T,x} = \left(\frac{\partial G_i}{\partial P}\right)_T \qquad \text{and} \qquad \left(\frac{\partial \bar{G}_i^{id}}{\partial T}\right)_{P,x} = \left(\frac{\partial G_i}{\partial T}\right)_P + R \ln x_i$$

Equation (4-17) implies that

$$\left(\frac{\partial G_i}{\partial P}\right)_T = V_i \qquad \text{and} \qquad \left(\frac{\partial G_i}{\partial T}\right)_P = -S_i$$

In combination these sets of equations provide

$$\bar{V}_i^{id} = V_i \tag{4-210}$$

and
$$\bar{S}_i^{id} = S_i - R \ln x_i \tag{4-211}$$

Because $\bar{H}_i^{id} = \bar{G}_i^{id} + T\bar{S}_i^{id}$, substitutions by Eqs. (4-209) and (4-211) yield

$$\bar{H}_i^{id} = H_i \tag{4-212}$$

The summability relation, Eq. (4-174), written for the special case of an ideal solution, may be applied to Eqs. (4-209) through (4-212):

$$G^{id} = \sum_i x_i G_i + RT \sum_i x_i \ln x_i \tag{4-213}$$

$$V^{id} = \sum_i x_i V_i \tag{4-214}$$

$$S^{id} = \sum_i x_i S_i - R \sum_i x_i \ln x_i \tag{4-215}$$

$$H^{id} = \sum_i x_i H_i \tag{4-216}$$

A simple equation for the fugacity of a species in an ideal solution follows from Eq. (4-209). For the special case of species i in an ideal solution, Eq. (4-202) becomes

$$\mu_i^{id} = \bar{G}_i^{id} = \Gamma_i(T) + RT \ln \hat{f}_i^{id}$$

When this equation and Eq. (4-199) are combined with Eq. (4-209), $\Gamma_i(T)$ is eliminated, and the resulting expression reduces to

$$\hat{f}_i^{id} = x_i f_i \tag{4-217}$$

This equation, known as the *Lewis-Randall rule*, shows that the fugacity of each species in an ideal solution is proportional to its mole fraction; the proportionality constant is the fugacity of *pure* species i in the same physical state as the solution and at the same T and P. Division of both sides of Eq. (4-217) by $x_i P$ and substitution of $\hat{\phi}_i^{id}$ for $\hat{f}_i^{id}/x_iP$ [Eq. (4-204)] and of ϕ_i for f_i/P [Eq. (4-201)] give the alternative form

$$\hat{\phi}_i^{id} = \phi_i \tag{4-218}$$

Thus the fugacity coefficient of species i in an ideal solution equals the fugacity coefficient of *pure* species i in the same physical state as the solution and at the same T and P.

Ideal solution behavior is often approximated by solutions comprised of molecules not too different in size and of the same chemical nature. Thus, a mixture of isomers conforms very closely to ideal solution behavior. So do mixtures of adjacent members of a homologous series.

Excess Properties An excess property M^E is defined as the difference between the actual property value of a solution and the value it would have as an ideal solution at the same T, P, and composition. Thus,

$$M^E \equiv M - M^{id} \tag{4-219}$$

where M represents the molar (or unit-mass) value of any extensive thermodynamic property (say, V, U, H, S, G). This definition is analogous to the definition of a residual property as given by Eq. (4-40). However, excess properties have no meaning for pure species, whereas residual properties exist for pure species as well as for mixtures. Partial molar excess properties $\overline{M}_i^E$ are defined analogously:

$$\overline{M}_i^E = \overline{M}_i - \overline{M}_i^{id} \tag{4-220}$$

Of particular interest is the partial molar excess Gibbs energy. Equation (4-202) may be written as

$$\overline{G}_i = \Gamma_i(T) + RT \ln \hat{f}_i$$

In accord with Eq. (4-217) for an ideal solution, this becomes

$$\overline{G}_i^{id} = \Gamma_i(T) + RT \ln x_i f_i$$

By difference

$$\overline{G}_i - \overline{G}_i^{id} = RT \ln \frac{\hat{f}_i}{x_i f_i}$$

The left side is the partial excess Gibbs energy $\overline{G}_i^E$; the dimensionless ratio $\hat{f}_i/x_i f_i$ on the right is the *activity coefficient of species i in solution*, given the symbol γ_i, and *by definiton*,

$$\gamma_i \equiv \frac{\hat{f}_i}{x_i f_i} \tag{4-221}$$

Thus,

$$\overline{G}_i^E = RT \ln \gamma_i \tag{4-222}$$

Comparison with Eq. (4-203) shows that Eq. (4-222) relates γ_i to $\overline{G}_i^E$ exactly as Eq. (4-203) relates $\hat{\phi}_i$ to $\overline{G}_i^R$. For an ideal solution, $\overline{G}_i^E = 0$, and therefore $\gamma_i = 1$.

Property Changes of Mixing A property change of mixing is defined by

$$\Delta M \equiv M - \sum_i x_i M_i \tag{4-223}$$

where M represents a molar thermodynamic property of a homogeneous solution and M_i is the molar property of pure species i at the T and P of the solution and in the same physical state. Applications are usually to liquids.

Each of Eqs. (4-213) through (4-216) is an expression for an ideal solution property, and each may be combined with the defining equation for an excess property [Eq. (4-219)], yielding the equations of the first column of Table 4-5. In view of Eq. (4-223) these may be written as shown in the second column of Table 4-5, where ΔG, ΔV, ΔS, and ΔH are the Gibbs energy change of mixing, the volume change of mixing, the entropy change of mixing, and the enthalpy change of mixing. For an ideal solution, each excess property is zero, and for this special case the equations reduce to those shown in the third column of Table 4-5.

Property changes of mixing and excess properties are easily calculated one from the other. The most common property changes of mixing are the volume change of mixing ΔV and the enthalpy change of mixing ΔH, commonly called the *heat of mixing*. These properties are identical to the corresponding excess properties. Moreover, they are directly measurable, providing an experimental entry into the network of equations of solution thermodynamics.

FUNDAMENTAL PROPERTY RELATIONS BASED ON THE GIBBS ENERGY

Of the four fundamental property relations shown in the second column of Table 4-1, only Eq. (4-13) has as its special or canonical variables T, P, and $\{n_i\}$. It is therefore the basis for extension to several useful supplementary thermodynamic properties. Indeed an alternative form has been developed as Eq. (4-191). These equations are the first two entries in the upper left quadrant of Table 4-6, which is now to be filled out with important derived relationships.

Fundamental Residual-Property Relation Equation (4-191) is general and may be written for the special case of an ideal gas

$$d\left(\frac{nG^{ig}}{RT}\right) = \frac{nV^{ig}}{RT}dP - \frac{nH^{ig}}{RT^2}dT + \sum_i \frac{\overline{G}_i^{ig}}{RT}dn_i$$

Subtraction of this equation from Eq. (4-191) gives

$$d\left(\frac{nG^R}{RT}\right) = \frac{nV^R}{RT}dP - \frac{nH^R}{RT^2}dT + \sum_i \frac{\overline{G}_i^R}{RT}dn_i \tag{4-236}$$

where the definitions $G^R \equiv G - G^{ig}$ and $\overline{G}_i^R \equiv \overline{G}_i - \overline{G}_i^{ig}$ have been imposed. Equation (4-236) is the *fundamental residual-property relation*. An alternative form follows by introduction of the fugacity coefficient given by Eq. (4-203). The result is listed as Eq. (4-237) in the upper left quadrant of Table 4-6.

Limited forms of this equation are particularly useful. Division by dP and restriction to constant T and composition lead to

$$\frac{V^R}{RT} = \left[\frac{\partial(G^R/RT)}{\partial P}\right]_{T,x} \tag{4-238}$$

Similarly, the result of division by dT and restriction to constant P and composition is

$$\frac{H^R}{RT} = -T\left[\frac{\partial(G^R/RT)}{\partial T}\right]_{P,x} \tag{4-239}$$

Also implicit in Eq. (4-237) is the relation

$$\ln \hat{\phi}_i = \left[\frac{\partial(nG^R/RT)}{\partial n_i}\right]_{T,P,n_j} \tag{4-240}$$

This equation demonstrates that $\ln \hat{\phi}_i$ is a partial property with respect to G^R/RT. The summability relation therefore applies, and

$$\frac{G^R}{RT} = \sum_i x_i \ln \hat{\phi}_i \tag{4-241}$$

TABLE 4-5 Relations Connecting Property Changes of Mixing and Excess Properties

M^E in relation to M		M^E in relation to ΔM		Expressions for ΔM^{id}	
$G^E = G - \sum_i x_i G_i - RT \sum_i x_i \ln x_i$	(4-224)	$G^E = \Delta G - RT \sum_i x_i \ln x_i$	(4-228)	$\Delta G^{id} = RT \sum_i x_i \ln x_i$	(4-232)
$V^E = V - \sum_i x_i V_i$	(4-225)	$V^E = \Delta V$	(4-229)	$\Delta V^{id} = 0$	(4-233)
$S^E = S - \sum_i x_i S_i + R \sum_i x_i \ln x_i$	(4-226)	$S^E = \Delta S + R \sum_i x_i \ln x_i$	(4-230)	$\Delta S^{id} = -R \sum_i x_i \ln x_i$	(4-234)
$H^E = H - \sum_i x_i H_i$	(4-227)	$H^E = \Delta H$	(4-231)	$\Delta H^{id} = 0$	(4-235)

TABLE 4-6 Fundamental Property Relations for the Gibbs Energy and Related Properties

General equations for an open system		Equations for 1 mol (constant composition)	
$d(nG) = nV\,dP - nS\,dT + \sum_i \mu_i\,dn_i$	(4-13)	$dG = V\,dP - S\,dT$	(4-17)
$d\left(\frac{nG}{RT}\right) = \frac{nV}{RT}dP - \frac{nH}{RT^2}dT + \sum_i \frac{\overline{G}_i}{RT}dn_i$	(4-191)	$d\left(\frac{G}{RT}\right) = \frac{V}{RT}dP - \frac{H}{RT^2}dT$	(4-253)
$d\left(\frac{nG^R}{RT}\right) = \frac{nV^R}{RT}dP - \frac{nH^R}{RT^2}dT + \sum_i \ln\hat{\phi}_i\,dn_i$	(4-237)	$d\left(\frac{G^R}{RT}\right) = \frac{V^R}{RT}dP - \frac{H^R}{RT^2}dT$	(4-254)
$d\left(\frac{nG^E}{RT}\right) = \frac{nV^E}{RT}dP - \frac{nH^E}{RT^2}dT + \sum_i \ln\gamma_i\,dn_i$	(4-248)	$d\left(\frac{G^E}{RT}\right) = \frac{V^E}{RT}dP - \frac{H^E}{RT^2}dT$	(4-255)
Equations for partial molar properties (constant composition)		**Gibbs-Duhem equations**	
$d\overline{G}_i = d\mu_i = \overline{V}_i\,dP - \overline{S}_i\,dT$	(4-256)	$V\,dP - S\,dT = \sum_i x_i\,d\mu_i$	(4-260)
$d\left(\frac{\overline{G}_i}{RT}\right) = d\left(\frac{\mu_i}{RT}\right) = \frac{\overline{V}_i}{RT}dP - \frac{\overline{H}_i}{RT^2}dT$	(4-257)	$\frac{V}{RT}dP - \frac{H}{RT^2}dT = \sum_i x_i\,d\left(\frac{\overline{G}_i}{RT}\right)$	(4-261)
$d\left(\frac{\overline{G}_i^R}{RT}\right) = d\ln\hat{\phi}_i = \frac{\overline{V}_i^R}{RT}dP - \frac{\overline{H}_i^R}{RT^2}dT$	(4-258)	$\frac{V^R}{RT}dP - \frac{H^R}{RT^2}dT = \sum_i x_i\,d\ln\hat{\phi}_i$	(4-262)
$d\left(\frac{\overline{G}_i^E}{RT}\right) = d\ln\gamma_i = \frac{\overline{V}_i^E}{RT}dP - \frac{\overline{H}_i^E}{RT^2}dT$	(4-259)	$\frac{V^E}{RT}dP - \frac{H^E}{RT^2}dT = \sum_i x_i\,d\ln\gamma_i$	(4-263)

Application of Eq. (4-240) to an expression giving G^R as a function of composition yields an equation for $\ln\hat{\phi}_i$. In the simplest case of a gas mixture for which the virial equation [Eq. (4-67)] is appropriate, Eq. (4-69) provides the relation

$$\frac{nG^R}{RT} = \frac{P}{RT}(nB)$$

Differentiation in accord with Eqs. (4-240) and (4-181) yields

$$\ln\hat{\phi}_i = \frac{P}{RT}\overline{B}_i \qquad (4\text{-}242)$$

where $\overline{B}_i$ is given by Eq. (4-182). For a binary system these equations reduce to

$$\ln\hat{\phi}_1 = \frac{P}{RT}(B_{11} + y_2^2\delta_{12}) \qquad (4\text{-}243a)$$

$$\ln\hat{\phi}_2 = \frac{P}{RT}(B_{22} + y_1^2\delta_{12}) \qquad (4\text{-}243b)$$

where $\qquad \delta_{12} \equiv 2B_{12} - B_{11} - B_{22}$

For the special case of pure species i, these equations reduce to

$$\ln\phi_i = \frac{P}{RT}B_{ii} \qquad (4\text{-}244)$$

For the generic cubic equation of state [Eqs. (4-104)], G^R/RT is given by Eq. (4-109), which in view of Eq. (4-200) for a pure species becomes

$$\ln\phi_i = Z_i - 1 - \ln(Z_i - \beta_i) - q_iI_i \qquad (4\text{-}245)$$

For species i in solution Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 562–563, McGraw-Hill, New York (2005)] show that

$$\ln\hat{\phi}_i = \frac{\overline{b}_i}{b}(Z - 1) - \ln(Z - \beta) - \overline{q}_iI \qquad (4\text{-}246)$$

Symbols without subscripts represent mixture properties, and I is given by Eq. (4-112).

Fundamental Excess-Property Relation Equations for excess properties are developed in much the same way as those for residual properties. For the special case of an ideal solution, Eq. (4-191) becomes

$$d\left(\frac{nG^{id}}{RT}\right) = \frac{nV^{id}}{RT}dP - \frac{nH^{id}}{RT^2}dT + \sum_i \frac{\overline{G}_i^{id}}{RT}dn_i$$

Subtraction of this equation from Eq. (4-191) yields

$$d\left(\frac{nG^E}{RT}\right) = \frac{nV^E}{RT}dP - \frac{nH^E}{RT^2}dT + \sum_i \frac{\overline{G}_i^E}{RT}dn_i \qquad (4\text{-}247)$$

where the definitions $G^E \equiv G - G^{id}$ and $\overline{G}_i^E \equiv \overline{G}_i - \overline{G}_i^{id}$ have been imposed. Equation (4-247) is the *fundamental excess-property relation*. An alternative form follows by introduction of the activity coefficient as given by Eq. (4-222). This result is listed as Eq. (4-248) in the upper left quadrant of Table 4-6.

The following equations are in complete analogy to those for residual properties.

$$\frac{V^E}{RT} = \left[\frac{\partial(G^E/RT)}{\partial P}\right]_{T,x} \qquad (4\text{-}249)$$

$$\frac{H^E}{RT} = -T\left[\frac{\partial(G^E/RT)}{\partial T}\right]_{P,x} \qquad (4\text{-}250)$$

$$\ln\gamma_i = \left[\frac{\partial(nG^E/RT)}{\partial n_i}\right]_{T,P,n_j} \qquad (4\text{-}251)$$

This last equation demonstrates that $\ln\gamma_i$ is a partial property with respect to G^E/RT, implying also the validity of the summability relation

$$\frac{G^E}{RT} = \sum_i x_i\ln\gamma_i \qquad (4\text{-}252)$$

The equations of the upper left quadrant of Table 4-6 reduce to those of the upper right quadrant for $n = 1$ and $dn_i = 0$. Each equation in the upper left quadrant has a partial-property analog, as shown in the lower left quadrant. Each equation of the upper left quadrant is a special case of Eq. (4-172) and therefore has associated with it a Gibbs-Duhem equation of the form of Eq. (4-173). These are shown in the lower right quadrant. The equations of Table 4-6 store an enormous amount of information, but they are so general that their direct

application is seldom appropriate. However, by inspection one can write a vast array of relations valid for particular applications. For example, one sees immediately from Eqs. (4-258) and (4-259) that

$$\left(\frac{\partial \ln \hat{\phi}_i}{\partial P}\right)_{T,x} = \frac{\overline{V}_i^R}{RT} \tag{4-264}$$

$$\left(\frac{\partial \ln \hat{\phi}_i}{\partial T}\right)_{P,x} = -\frac{\overline{H}_i^R}{RT^2} \tag{4-265}$$

$$\left(\frac{\partial \ln \gamma_i}{\partial P}\right)_{T,x} = \frac{\overline{V}_i^E}{RT} \tag{4-266}$$

$$\left(\frac{\partial \ln \gamma_i}{\partial T}\right)_{P,x} = -\frac{\overline{H}_i^E}{RT^2} \tag{4-267}$$

MODELS FOR THE EXCESS GIBBS ENERGY

Excess properties find application in the treatment of liquid solutions. Of primary importance for engineering calculations is the excess Gibbs energy G^E, because its canonical variables are T, P, and composition, the variables usually specified or sought in design calculations. Knowing G^E as a function of T, P, and composition, one can in principle compute from it all other excess properties.

The excess volume for liquid mixtures is usually small, and in accord with Eq. (4-249) the pressure dependence of G^E is usually ignored. Thus, engineering efforts to model G^E center on representing its composition and temperature dependence. For binary systems *at constant* T, G^E becomes a function of just x_1, and the quantity most conveniently represented by an equation is G^E/x_1x_2RT. The simplest procedure is to express this quantity as a power series in x_1:

$$\frac{G^E}{x_1x_2RT} = a + bx_1 + cx_1^2 + \cdots \qquad \text{(constant } T\text{)}$$

An equivalent power series with certain advantages is the *Redlich-Kister expansion* [Redlich, Kister, and Turnquist, *Chem. Eng. Progr. Symp. Ser. No. 2*, **48:** 49–61 (1952)]:

$$\frac{G^E}{x_1x_2RT} = A + B(x_1 - x_2) + C(x_1 - x_2)^2 + \cdots$$

In application, different truncations of this expansion are appropriate, and for each truncation specific expressions for $\ln \gamma_1$ and $\ln \gamma_2$ result from application of Eq. (4-251). When all parameters are zero, $G^E/RT = 0$, and the solution is ideal. If $B = C = \cdots = 0$, then

$$\frac{G^E}{x_1x_2RT} = A$$

where A is a constant for a given temperature. The corresponding equations for $\ln \gamma_1$ and $\ln \gamma_2$ are

$$\ln \gamma_1 = Ax_2^2 \tag{4-268a}$$

$$\ln \gamma_2 = Ax_1^2 \tag{4-268b}$$

The symmetric nature of these relations is evident. The infinite dilution values of the activity coefficients are $\ln \gamma_1^\infty = \ln \gamma_2^\infty = A$.

If $C = \cdots = 0$, then

$$\frac{G^E}{x_1x_2RT} = A + B(x_1 - x_2) = A + B(2x_1 - 1)$$

and in this case G^E/x_1x_2RT is linear in x_1. The substitutions $A + B = A_{21}$ and $A–B = A_{12}$ transform this expression to the *Margules equation*:

$$\frac{G^E}{x_1x_2RT} = A_{21}x_1 + A_{12}x_2 \tag{4-269}$$

Application of Eq. (4-251) yields

$$\ln \gamma_1 = x_2^2\,[A_{12} + 2(A_{21} - A_{12})\,x_1] \tag{4-270a}$$

$$\ln \gamma_2 = x_1^2\,[A_{21} + 2(A_{12} - A_{21})\,x_2] \tag{4-270b}$$

When $x_1 = 0$, $\ln \gamma_1^\infty = A_{12}$; when $x_2 = 0$, $\ln \gamma_2^\infty = A_{21}$.

An alternative equation is obtained when the reciprocal quantity x_1x_2RT/G^E is expressed as a linear function of x_1:

$$\frac{x_1x_2}{G^E/RT} = A' + B'(x_1 - x_2) = A' + B'(2x_1 - 1)$$

This may also be written as

$$\frac{x_1x_2}{G^E/RT} = A'(x_1 + x_2) + B'(x_1 - x_2) = (A' + B')x_1 + (A' - B')\,x_2$$

The substitutions $A' + B' = 1/A'_{21}$ and $A' - B' = 1/A'_{12}$ ultimately produce

$$\frac{G^E}{x_1x_2RT} = \frac{A'_{12}A'_{21}}{A'_{12}x_1 + A'_{21}x_2} \tag{4-271}$$

The activity coefficients implied by this equation are given by

$$\ln \gamma_1 = A'_{12}\left(1 + \frac{A'_{12}x_1}{A'_{21}x_2}\right)^{-2} \tag{4-272a}$$

$$\ln \gamma_2 = A'_{21}\left(1 + \frac{A'_{21}x_2}{A'_{12}x_1}\right)^{-2} \tag{4-272b}$$

These are the *van Laar equations*. When $x_1 = 0$, $\ln \gamma_1^\infty = A'_{12}$; when $x_2 = 0$, $\ln \gamma_2^\infty = A'_{21}$.

The Redlich-Kister expansion, the Margules equations, and the van Laar equations are all special cases of a very general treatment based on rational functions, i.e., on equations for G^E given by ratios of polynomials [Van Ness and Abbott, *Classical Thermodynamics of Nonelectrolyte Solutions: With Applications to Phase Equilibria*, Sec. 5-7, McGraw-Hill, New York (1982)]. Although providing great flexibility in the fitting of VLE data for binary systems, they are without theoretical foundation, with no basis in theory for their extension to multicomponent systems. Nor do they incorporate an explicit temperature dependence for the parameters.

Theoretical developments in the molecular thermodynamics of liquid solution behavior are often based on the concept of *local composition*, presumed to account for the short-range order and nonrandom molecular orientations resulting from differences in molecular size and intermolecular forces. Introduced by G. M. Wilson [*J. Am. Chem. Soc.* **86:** 127–130 (1964)] with the publication of a model for G^E, this concept prompted the development of alternative local composition models, most notably the NRTL (Non-Random Two-Liquid) equation of Renon and Prausnitz [*AIChE J.* **14:** 135–144 (1968)] and the UNIQUAC (UNIversal QUAsi-Chemical) equation of Abrams and Prausnitz [*AIChE J.* **21:** 116–128 (1975)].

The Wilson equation, like the Margules and van Laar equations, contains just two parameters for a binary system (Λ_{12} and Λ_{21}) and is written as

$$\frac{G^E}{RT} = -x_1 \ln(x_1 + x_2\Lambda_{12}) - x_2 \ln(x_2 + x_1\Lambda_{21}) \tag{4–273}$$

$$\ln \gamma_1 = -\ln(x_1 + x_2\Lambda_{12}) + x_2\left(\frac{\Lambda_{12}}{x_1 + x_2\Lambda_{12}} - \frac{\Lambda_{21}}{x_2 + x_1\Lambda_{21}}\right) \tag{4-274a}$$

$$\ln \gamma_2 = -\ln(x_2 + x_1\Lambda_{21}) - x_1\left(\frac{\Lambda_{12}}{x_1 + x_2\Lambda_{12}} - \frac{\Lambda_{21}}{x_2 + x_1\Lambda_{21}}\right) \tag{4-274b}$$

At infinite dilution,

$$\ln \gamma_1^\infty = -\ln \Lambda_{12} + 1 - \Lambda_{21} \qquad \ln \gamma_2^\infty = -\ln \Lambda_{21} + 1 - \Lambda_{12}$$

Both Λ_{12} and Λ_{21} must be positive numbers.

The NRTL equation contains three parameters for a binary system and is written as

$$\frac{G^E}{x_1 x_2 RT} = \frac{G_{21}\tau_{21}}{x_1 + x_2 G_{21}} + \frac{G_{12}\tau_{12}}{x_2 + x_1 G_{12}} \qquad (4\text{-}275)$$

$$\ln \gamma_1 = x_2^2 \left[\tau_{21} \left(\frac{G_{21}}{x_1 + x_2 G_{21}} \right)^2 + \frac{G_{12}\tau_{12}}{(x_2 + x_1 G_{12})^2} \right] \qquad (4\text{-}276a)$$

$$\ln \gamma_2 = x_1^2 \left[\tau_{12} \left(\frac{G_{12}}{x_2 + x_1 G_{12}} \right)^2 + \frac{G_{21}\tau_{21}}{(x_1 + x_2 G_{21})^2} \right] \qquad (4\text{-}276b)$$

Here $\qquad G_{12} = \exp(-\alpha\tau_{12}) \qquad G_{21} = \exp(-\alpha\tau_{21})$

and $\qquad \tau_{12} = \dfrac{b_{12}}{RT} \qquad \tau_{21} = \dfrac{b_{21}}{RT}$

where α, b_{12}, and b_{21}, parameters specific to a particular pair of species, are independent of composition and temperature. The infinite dilution values of the activity coefficients are

$$\ln \gamma_1^\infty = \tau_{21} + \tau_{12} \exp(-\alpha\tau_{12}) \qquad \ln \gamma_2^\infty = \tau_{12} + \tau_{21} \exp(-\alpha\tau_{21})$$

The local composition models have limited flexibility in the fitting of data, but they are adequate for most engineering purposes. Moreover, they are implicitly generalizable to multicomponent systems without the introduction of any parameters beyond those required to describe the constitutent binary systems. For example, the Wilson equation for multicomponent systems is written as

$$\frac{G^E}{RT} = -\sum_i x_i \ln \left(\sum_j x_j \Lambda_{ij} \right) \qquad (4\text{-}277)$$

and

$$\ln \gamma_i = 1 - \ln \left(\sum_j x_j \Lambda_{ij} \right) - \sum_k \frac{x_k \Lambda_{ki}}{\sum_j x_j \Lambda_{kj}} \qquad (4\text{-}278)$$

where $\Lambda_{ij} = 1$ for $i = j$, etc. All indices in these equations refer to the same species, and all summations are over *all* species. For each ij pair there are two parameters, because $\Lambda_{ij} \neq \Lambda_{ji}$. For example, in a ternary system the three possible ij pairs are associated with the parameters Λ_{12}, Λ_{21}; Λ_{13}, Λ_{31}; and Λ_{23}, Λ_{32}.

The temperature dependence of the parameters is given by

$$\Lambda_{ij} = \frac{V_j}{V_i} \exp \frac{-a_{ij}}{RT} \qquad i \neq j \qquad (4\text{-}279)$$

where V_j and V_i are the molar volumes of pure liquids j and i and a_{ij} is a constant independent of composition and temperature. Molar volumes V_j and V_i, themselves weak functions of temperature, form ratios that in practice may be taken as independent of T, and are usually evaluated at or near 25°C.

The Wilson parameters Λ_{ij} and NRTL parameters G_{ij} inherit a Boltzmann-type T dependence from the origins of the expressions for G^E, but it is only approximate. Computations of properties sensitive to this dependence (e.g., heats of mixing and liquid/liquid solubility) are in general only qualitatively correct. However, all parameters are found from data for binary (in contrast to multicomponent) systems, and this makes parameter determination for the local composition models a task of manageable proportions.

The UNIQUAC equation treats $g \equiv G^E/RT$ as made up of two additive parts, a *combinatorial* term g^C, accounting for molecular size and shape differences, and a *residual* term g^R (not a residual property), accounting for molecular interactions:

$$g = g^C + g^R \qquad (4\text{-}280)$$

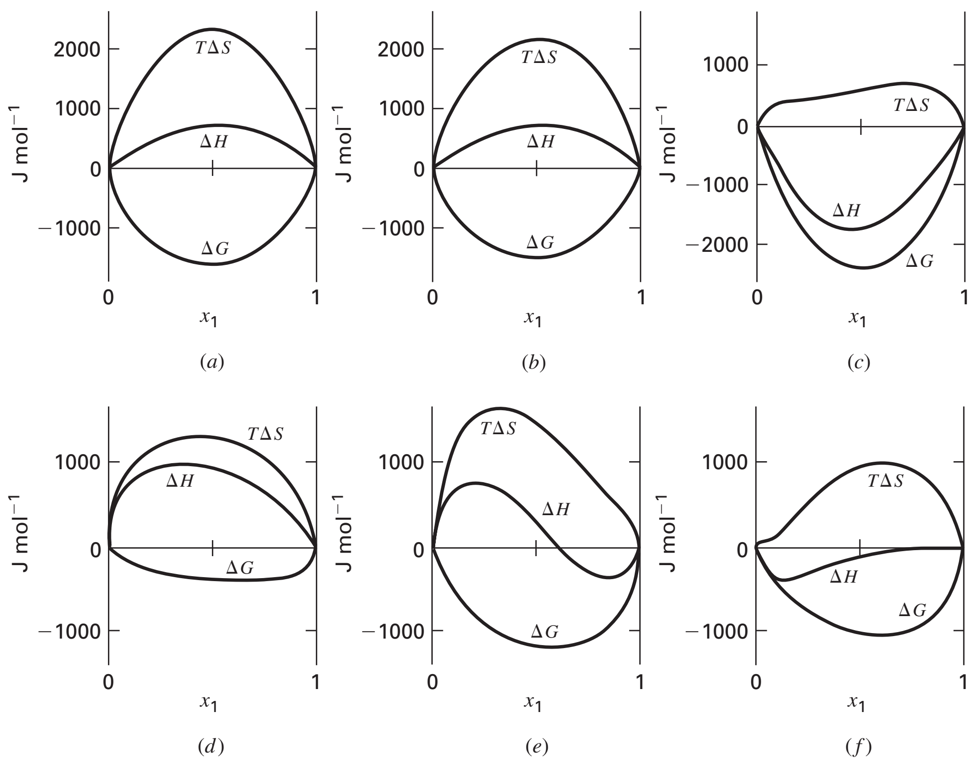

FIG. 4-4 Property changes of mixing at 50°C for six binary liquid systems: (*a*) chloroform(1)/*n*-heptane(2); (*b*) acetone(1)/methanol(2); (*c*) acetone(1)/chloroform(2); (*d*) ethanol(1)/*n*-heptane(2); (*e*) ethanol(1)/chloroform(2); (*f*) ethanol(1)/water(2). [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 455, McGraw-Hill, New York (2005).*]

Function g^C contains pure-species parameters only, whereas function g^R incorporates two *binary* parameters for each pair of molecules. For a multicomponent system,

$$g^C = \sum_i x_i \ln \frac{\Phi_i}{x_i} + 5\sum_i q_i x_i \ln \frac{\theta_i}{\Phi_i} \tag{4-281}$$

$$g^R = -\sum_i q_i x_i \ln \left(\sum_j \theta_j \tau_{ji}\right) \tag{4-282}$$

where

$$\Phi_i \equiv \frac{x_i r_i}{\sum_j x_j r_j} \tag{4-283}$$

and

$$\theta_i \equiv \frac{x_i q_i}{\sum_j x_j q_j} \tag{4-284}$$

Subscript i identifies species, and j is a dummy index; all summations are over all species. Note that $\tau_{ji} \neq \tau_{ij}$; however, when $i = j$, then $\tau_{ii} = \tau_{jj} = 1$. In these equations r_i (a relative molecular volume) and q_i (a relative molecular surface area) are pure-species parameters. The influence of temperature on g enters through the interaction parameters τ_{ji} of Eq. (4-282), which are temperature-dependent:

$$\tau_{ji} = \exp \frac{-(u_{ji} - u_{ii})}{RT} \tag{4-285}$$

Parameters for the UNIQUAC equation are therefore values of $u_{ji} - u_{ii}$.

An expression for $\ln \gamma_i$ is found by application of Eq. (4-251) to the UNIQUAC equation for g [Eqs. (4-280) through (4-282)]. The result is given by the following equations:

$$\ln \gamma_i = \ln \gamma_i^C + \ln \gamma_i^R \tag{4-286}$$

$$\ln \gamma_i^C = 1 - J_i + \ln J_i - 5q_i\left(1 - \frac{J_i}{L_i} + \ln \frac{J_i}{L_i}\right) \tag{4-287}$$

$$\ln \gamma_i^R = q_i\left(1 - \ln s_i - \sum_j \theta_j \frac{\tau_{ij}}{s_j}\right) \tag{4-288}$$

where in addition to Eqs. (4-284) and (4-285),

$$J_i = \frac{r_i}{\sum_j r_j x_j} \tag{4-289}$$

$$L_i = \frac{q_i}{\sum_j q_j x_j} \tag{4-290}$$

$$s_i = \sum_l \theta_l \tau_{li} \tag{4-291}$$

Again subscript i identifies species, and j and l are dummy indices.

Values for the parameters of the commonly used models for the excess Gibbs energy are given by Gmehling, Onken, and Arlt [*Vapor-Liquid Equilibrium Data Collection,* Chemistry Data Series, vol. 1, parts 1–8, DECHEMA, Frankfurt/Main (1974–1990)].

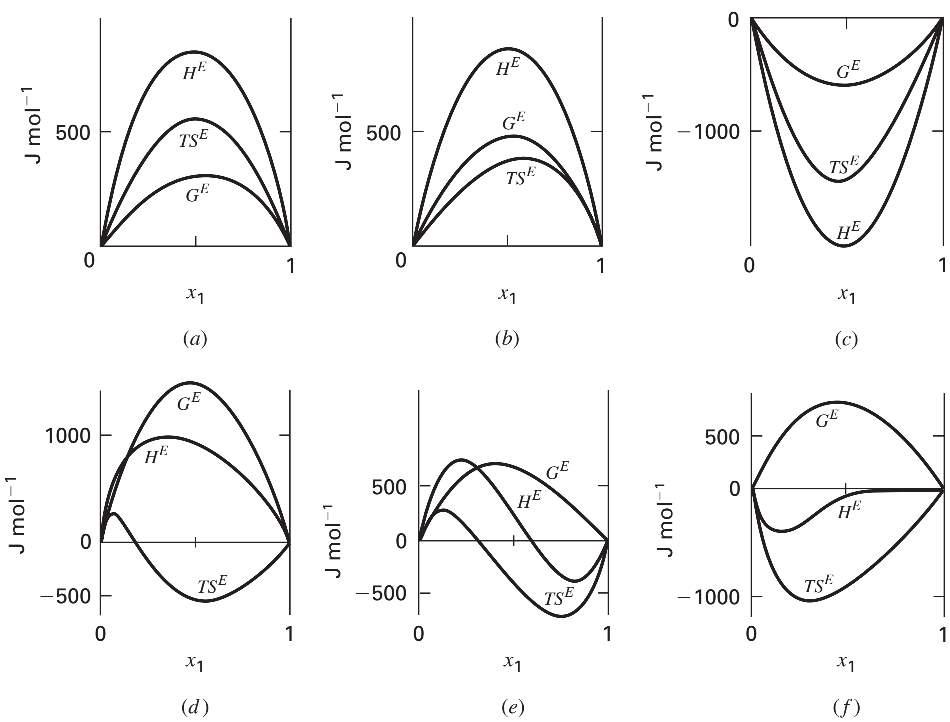

FIG. 4-5 Excess properties at 50°C for six binary liquid systems: (*a*) chloroform(1)/*n*-heptane(2); (*b*) acetone(1)/methanol(2); (*c*) acetone(1)/chloroform(2); (*d*) ethanol(1)/*n*-heptane(2); (*e*) ethanol(1)/chloroform(2); (*f*) ethanol(1)/water(2). [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 420, McGraw-Hill, New York (2005).*]

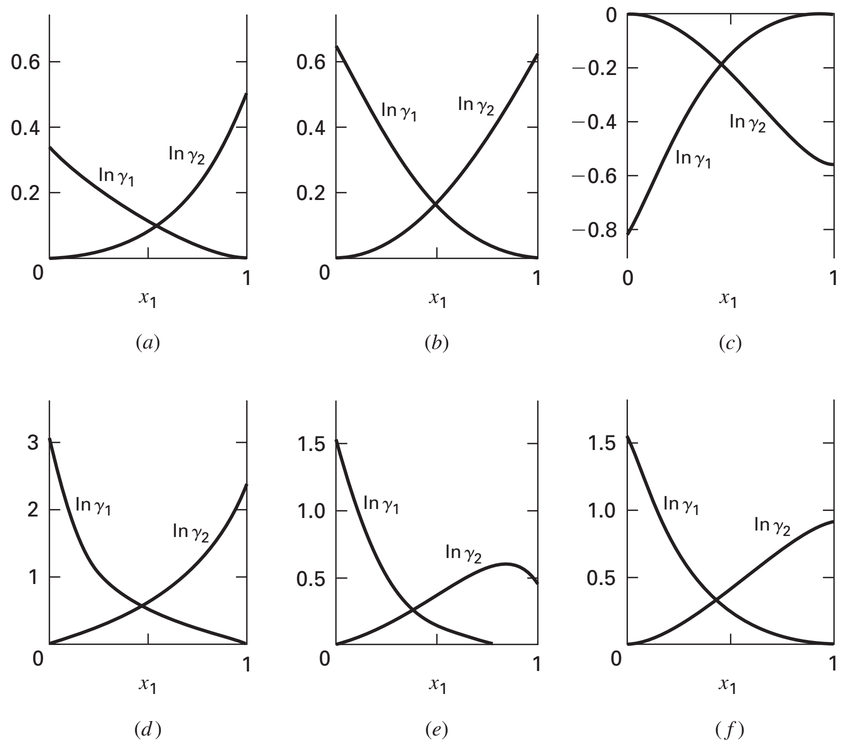

FIG. 4-6 Activity coefficients at 50°C for six binary liquid systems: (*a*) chloroform(1)/*n*-heptane(2); (*b*) acetone(1)/methanol(2); (*c*) acetone(1)/chloroform(2); (*d*) ethanol(1)/*n*-heptane(2); (*e*) ethanol(1)/chloroform(2); (*f*) ethanol(1)/water(2). [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 445, McGraw-Hill, New York (2005).*]

Behavior of Binary Liquid Solutions Property changes of mixing and excess properties find greatest application in the description of liquid mixtures at low reduced temperatures, i.e., at temperatures well below the critical temperature of each constituent species. The properties of interest to the chemical engineer are V^E ($\equiv \Delta V$), H^E ($\equiv \Delta H$), S^E, ΔS, G^E, and ΔG. The activity coefficient is also of special importance because of its application in phase equilibrium calculations.

The volume change of mixing ($V^E = \Delta V$), the heat of mixing ($H^E = \Delta H$), and the excess Gibbs energy G^E are experimentally accessible, ΔV and ΔH by direct measurement and G^E (or $\ln \gamma_i$) indirectly by reduction of vapor/liquid equilibrium data. Knowledge of H^E and G^E allows calculation of S^E by Eq. (4-10), written for excess properties as

$$S^E = \frac{H^E - G^E}{T} \tag{4-292}$$

with ΔS then given by Eq. (4-230).

Figure 4-4 displays plots of ΔH, ΔS, and ΔG as functions of composition for six binary solutions at 50°C. The corresponding excess properties are shown in Fig. 4-5; the activity coefficients, derived from Eq. (4-251), appear in Fig. 4-6. The properties shown here are insensitive to pressure and for practical purposes represent solution properties at 50°C and low pressure ($P \approx 1$ bar).

EQUILIBRIUM

CRITERIA

The equations developed in preceding sections are for *PVT* systems in states of internal equilibrium. The criteria for internal thermal and mechanical equilibrium simply require uniformity of temperature and pressure throughout the system. The criteria for phase and chemical reaction equilibria are less obvious.

If a closed *PVT* system of uniform *T* and *P*, either homogeneous or heterogeneous, is in thermal and mechanical equilibrium with its surroundings, but is not at internal equilibrium with respect to mass transfer or chemical reaction, then changes in the system are irreversible and necessarily bring the system closer to an equilibrium state. The first and second laws written for the entire system are

$$dU^t = dQ + dW \qquad dS^t \geq \frac{dQ}{T}$$

Combination gives $\qquad dU^t - dW - T\,dS^t \leq 0$

Because mechanical equilibrium is assumed, $dW = -P dV^t$, whence

$$dU^t + P dV^t - T\,dS^t \leq 0$$

The inequality applies to all incremental changes toward the equilibrium state, whereas the equality holds at the equilibrium state where change is reversible.

Constraints put on this expression produce alternative criteria for the directions of irreversible processes and for the condition of equilibrium. For example, $dU^t_{S^t,V^t} \leq 0$. Particularly important is fixing *T* and *P*; this produces

$$d(U^t + PV^t - TS^t)_{T,P} \leq 0 \quad \text{or} \quad dG^t_{T,P} \leq 0$$

This expression shows that all irreversible processes occurring at constant T and P proceed in a direction such that the total Gibbs energy of the system decreases. Thus the equilibrium state of a closed system is the state with the minimum total Gibbs energy attainable at the given T and P. At the equilibrium state, differential variations may occur in the system at constant T and P without producing a change in G^t. This is the meaning of the equilibrium criterion

$$dG^t_{T,P} = 0 \tag{4-293}$$

This equation may be applied to a closed, nonreactive, two-phase system. Each phase taken separately is an *open* system, capable of exchanging mass with the other; Eq. (4-13) is written for each phase:

$$d(nG)' = -(nS)'\,dT + (nV)'\,dP + \sum_i \mu_i'\,dn_i'$$

$$d(nG)'' = -(nS)''\,dT + (nV)''\,dP + \sum_i \mu_i''\,dn_i''$$

where the primes and double primes denote the two phases; the presumption is that T and P are uniform throughout the two phases. The change in the Gibbs energy of the two-phase system is the sum of these equations. When each total-system property is expressed by an equation of the form $nM = (nM)' + (nM)''$, this sum is given by

$$d(nG) = (nV)dP - (nS)dT + \sum_i \mu_i'\,dn_i' + \sum_i \mu_i''\,dn_i''$$

If the two-phase system is at equilibrium, then application of Eq. (4-293) yields

$$dG^t_{T,P} \equiv d(nG)_{T,P} = \sum_i \mu_i'\,dn_i' + \sum_i \mu_i''\,dn_i'' = 0$$

The system is closed and without chemical reaction; material balances therefore require that $dn_i'' = -dn_i'$, reducing the preceding equation to

$$\sum_i (\mu_i' - \mu_i'')\,dn_i' = 0$$

Because the dn_i' are independent and arbitrary, it follows that $\mu_i' = \mu_i''$. This is the criterion of two-phase equilibrium. It is readily generalized to multiple phases by successive application to pairs of phases. The general result is

$$\mu_i' = \mu_i'' = \mu_i''' = \cdots \tag{4-294}$$

Substitution for each μ_i by Eq. (4-202) produces the equivalent result:

$$\hat{f}_i' = \hat{f}_i'' = \hat{f}_i''' = \cdots \tag{4-295}$$

These are the criteria of phase equilibrium applied in the solution of practical problems.

For the case of equilibrium with respect to chemical reaction within a single-phase closed system, combination of Eqs. (4-13) and (4-293) leads immediately to

$$\sum_i \mu_i\,dn_i = 0 \tag{4-296}$$

For a system in which both phase and chemical reaction equilibrium prevail, the criteria of Eqs. (4-295) and (4-296) are superimposed.

PHASE RULE

The *intensive* state of a *PVT* system is established when its temperature and pressure and the compositions of all phases are fixed. However, for equilibrium states not all these variables are independent, and fixing a limited number of them automatically establishes the others. This number of independent variables is given by the phase rule, and it is called the *number of degrees of freedom* of the system. It is the number of variables that may be arbitrarily specified and that must be so specified in order to fix the *intensive* state of a system at equilibrium. This number is the difference between the number of variables needed to characterize the system and the number of equations that may be written connecting these variables.

For a system containing N chemical species distributed at equilibrium among π phases, the phase rule variables are T and P, presumed uniform throughout the system, and $N - 1$ mole fractions in each phase. The number of these variables is $2 + (N - 1)\pi$. The masses of the phases are not phase rule variables, because they have nothing to do with the intensive state of the system.

The equilibrium equations that may be written express chemical potentials or fugacities as functions of T, P, and the phase compositions, the phase rule variables:

1. Equation (4-295) for each species, giving $(\pi - 1)N$ phase equilibrium equations
2. Equation (4-296) for each independent chemical reaction, giving r equations

The total number of independent equations is therefore $(\pi - 1)N + r$. Because the degrees of freedom of the system F is the difference between the number of variables and the number of equations,

$$F = 2 + (N - 1)\pi - (\pi - 1)N - r$$

or

$$F = 2 - \pi + N - r \tag{4-297}$$

The number of independent chemical reactions r can be determined as follows:

1. Write *formation* reactions from the elements for each chemical compound present in the system.
2. Combine these reaction equations so as to eliminate from the set all elements not present as elements in the system. A systematic procedure is to select one equation and combine it with each of the other equations of the set so as to eliminate a particular element. This usually reduces the set by one equation for each element eliminated, although two or more elements may be simultaneously eliminated.

The resulting set of r equations is a complete set of independent reactions. More than one such set is often possible, but all sets number r and are equivalent.

Example 2: Application of the Phase Rule

a. For a system of two miscible nonreacting species in vapor/liquid equilibrium,

$$F = 2 - \pi + N - r = 2 - 2 + 2 - 0 = 2$$

The 2 degrees of freedom for this system may be satisfied by setting T and P, or T and y_1, or P and x_1, or x_1 and y_1, etc., at fixed values. Thus for equilibrium at a particular T and P, this state (if possible at all) exists only at one liquid and one vapor composition. Once the 2 degrees of freedom are used up, no further specification is possible that would restrict the phase rule variables. For example, one cannot *in addition* require that the system form an azeotrope (assuming this is possible), for this requires $x_1 = y_1$, an equation not taken into account in the derivation of the phase rule. Thus the requirement that the system form an azeotrope imposes a special constraint, making $F = 1$.

b. For a gaseous system consisting of CO, CO_2, H_2, H_2O, and CH_4 in chemical reaction equilibrium,

$$F = 2 - \pi + N - r = 2 - 1 + 5 - 2 = 4$$

The value of $r = 2$ is found from the formation reactions:

$$C + \tfrac{1}{2}O_2 \rightarrow CO \qquad C + O_2 \rightarrow CO_2$$

$$H_2 + \tfrac{1}{2}O_2 \rightarrow H_2O \qquad C + 2H_2 \rightarrow CH_4$$

Systematic elimination of C and O_2 from this set of chemical equations reduces the set to two. Three possible pairs of equations may result, depending on how the combination of equations is effected. Any *pair* of the following three equations represents a complete set of independent reactions, and all pairs are equivalent.

$$CH_4 + H_2O \rightarrow CO + 3H_2$$

$$CO + H_2O \rightarrow CO_2 + H_2$$

$$CH_4 + 2H_2O \rightarrow CO_2 + 4H_2$$

The result, $F = 4$, means that one is free to specify, for example, T, P, and two mole fractions in an equilibrium mixture of these five chemical species, provided nothing else is arbitrarily set. Thus it cannot simultaneously be required that the system be prepared from specified amounts of particular constituent species.

Duhem's Theorem Because the phase rule treats only the intensive state of a system, it applies to both closed and open systems. Duhem's theorem, on the other hand, is a rule relating to closed systems only: *For any closed system formed initially from given masses of prescribed chemical species, the equilibrium state is* **completely**

determined *by any two properties of the system, provided only that the two properties are independently variable at the equilibrium state.* The meaning of completely determined is that both the intensive and extensive states of the system are fixed; not only are T, P, and the phase compositions established, but so also are the masses of the phases.

VAPOR/LIQUID EQUILIBRIUM

Vapor/liquid equilibrium (VLE) relationships (as well as other interphase equilibrium relationships) are needed in the solution of many engineering problems. The required data can be found by experiment, but measurements are seldom easy, even for binary systems, and they become ever more difficult as the number of species increases. This is the incentive for application of thermodynamics to the calculation of phase equilibrium relationships.

The general VLE problem treats a multicomponent system of N constituent species for which the independent variables are T, P, $N-1$ liquid-phase mole fractions, and $N-1$ vapor-phase mole fractions. (Note that $\Sigma_i x_i = 1$ and $\Sigma_i y_i = 1$, where x_i and y_i represent liquid and vapor mole fractions, respectively.) Thus there are $2N$ independent variables, and application of the phase rule shows that exactly N of these variables must be fixed to establish the intensive state of the system. This means that once N variables have been specified, the remaining N variables can be determined by simultaneous solution of the N equilibrium relations

$$\hat{f}_i^l = \hat{f}_i^v \qquad i = 1, 2, \ldots, N \tag{4-298}$$

where superscripts l and v denote the liquid and vapor phases, respectively.

In practice, either T or P *and* either the liquid-phase or vapor-phase composition are specified, thus fixing $1 + (N-1) = N$ independent variables. The remaining N variables are then subject to calculation, provided that sufficient information is available to allow determination of all necessary thermodynamic properties.

Gamma/Phi Approach For many VLE systems of interest, the pressure is low enough that a relatively simple equation of state, such as the two-term virial equation, is satisfactory for the vapor phase. Liquid-phase behavior, on the other hand, is described by an equation for the excess Gibbs energy, from which activity coefficients are derived. The fugacity of species i in the liquid phase is given by Eq. (4-221), and the vapor-phase fugacity is given by Eq. (4-204). These are here written as

$$\hat{f}_i^l = \gamma_i x_i f_i \quad \text{and} \quad \hat{f}_i^v = \hat{\phi}_i^v y_i P$$

By Eq. (4-298),

$$\gamma_i x_i f_i = \hat{\phi}_i y_i P \qquad i = 1, 2, \ldots, N \tag{4-299}$$

Identifying superscripts l and v are omitted here with the understanding that γ_i and f_i are liquid-phase properties, whereas $\hat{\phi}_i$ is a vapor-phase property. Applications of Eq. (4-299) represent what is known as the *gamma/phi* approach to VLE calculations.

Evaluation of $\hat{\phi}_i$ is usually by Eq. (4-243), based on the two-term virial equation of state. The activity coefficient γ_i is ultimately based on Eq. (4-251) applied to an expression for G^E/RT, as described in the section "Models for the Excess Gibbs Energy."

The fugacity f_i of pure compressed liquid i must be evaluated at the T and P of the equilibrium mixture. This is done in two steps. First, one calculates the fugacity coefficient of saturated vapor $\phi_i^v = \phi_i^{\text{sat}}$ by an integrated form of Eq. (4-205), most commonly by Eq. (4-242) evaluated for pure species i at temperature T and the corresponding vapor pressure $P = P_i^{\text{sat}}$. Equation (4-298) written for pure species i becomes

$$f_i^v = f_i^l = f_i^{\text{sat}} \tag{4-300}$$

where f_i^{sat} indicates the value both for saturated liquid and for saturated vapor. Division by P_i^{sat} yields corresponding fugacity coefficients:

$$\frac{f_i^{\text{sat}}}{P_i^{\text{sat}}} = \frac{f_i^v}{P_i^{\text{sat}}} = \frac{f_i^l}{P_i^{\text{sat}}}$$

or

$$\phi_i^v = \phi_i^l = \phi_i^{\text{sat}} \tag{4-301}$$

The second step is the evaluation of the change in fugacity of the liquid with a change in pressure to a value above or below P_i^{sat}. For this isothermal change of state from saturated liquid at P_i^{sat} to liquid at pressure P, Eq. (4-17) is integrated to give

$$G_i - G_i^{\text{sat}} = \int_{P_i^{\text{sat}}}^{P} V_i \, dP$$

Equation (4-199) is then written twice: for G_i and for G_i^{sat}. Subtraction provides another expression for $G_i - G_i^{\text{sat}}$:

$$G_i - G_i^{\text{sat}} = RT \ln \frac{f_i}{f_i^{\text{sat}}}$$

Equating the two expressions for $G_i - G_i^{\text{sat}}$ yields

$$\ln \frac{f_i}{f_i^{\text{sat}}} = \frac{1}{RT}\int_{P_i^{\text{sat}}}^{P} V_i \, dP$$

Because V_i, the liquid-phase molar volume, is a very weak function of P at temperatures well below T_c, an excellent approximation is usually obtained when evaluation of the integral is based on the assumption that V_i is constant at the value for saturated liquid V_i^l:

$$\ln \frac{f_i}{f_i^{\text{sat}}} = \frac{V_i^l(P - P_i^{\text{sat}})}{RT}$$

Substituting $f_i^{\text{sat}} = \phi_i^{\text{sat}} P_i^{\text{sat}}$ and solving for f_i give

$$f_i = \phi_i^{\text{sat}} P_i^{\text{sat}} \exp \frac{V_i^l(P - P_i^{\text{sat}})}{RT} \tag{4-302}$$

The exponential is known as the Poynting factor.

Equation (4-299) may now be written as

$$y_i P \Phi_i = x_i \gamma_i P_i^{\text{sat}} \qquad i = 1, 2, \ldots, N \tag{4-303}$$

where

$$\Phi_i = \frac{\hat{\phi}_i}{\phi_i^{\text{sat}}} \exp \frac{-V_i^l(P - P_i^{\text{sat}})}{RT} \tag{4-304}$$

If evaluation of ϕ_i^{sat} and $\hat{\phi}_i$ is by Eqs. (4-244) and (4-243), this reduces to

$$\Phi_i = \exp \frac{P\overline{B}_i - P_i^{\text{sat}} B_{ii} - V_i^l(P - P_i^{\text{sat}})}{RT} \tag{4-305}$$

where $\overline{B}_i$ is given by Eq. (4-182).

The N equations represented by Eq. (4-303) in conjunction with Eq. (4-305) may be solved for N unknown phase equilibrium variables. For a multicomponent system the calculation is formidable, but well suited to computer solution.

When Eq. (4-303) is applied to VLE for which the vapor phase is an ideal gas and the liquid phase is an ideal solution, it reduces to a very simple expression. For ideal gases, fugacity coefficients $\hat{\phi}_i$ and ϕ_i^{sat} are unity, and the right side of Eq. (4-304) reduces to the Poynting factor. For the systems of interest here, this factor is always very close to unity, and for practical purposes $\Phi_i = 1$. For ideal solutions, the activity coefficients γ_i are also unity, and Eq. (4-303) reduces to

$$y_i P = x_i P_i^{\text{sat}} \qquad i = 1, 2, \ldots, N \tag{4-306}$$

an equation which expresses *Raoult's law*. It is the simplest possible equation for VLE and as such fails to provide a realistic representation of real behavior for most systems. Nevertheless, it is useful as a standard of comparison.

Modified Raoult's Law Of the qualifications that lead to Raoult's law, the one least often reasonable is the supposition of solution ideality for the liquid phase. Real solution behavior is reflected by values of activity coefficients that differ from unity. When γ_i of Eq. (4-303) is retained in the equilibrium equation, the result is the *modified Raoult's law*:

$$y_i P = x_i \gamma_i P_i^{\text{sat}} \qquad i = 1, 2, \ldots, N \tag{4-307}$$

This equation is often adequate when applied to systems at low to moderate pressures and is therefore widely used. Bubble point and dew point calculations are only a bit more complex than the same calculations with Raoult's law.

Activity coefficients are functions of temperature and liquid-phase composition and are correlated through equations for the excess Gibbs energy. When an appropriate correlating equation for G^E is not available, suitable estimates of activity coefficients may often be obtained from a group contribution correlation. This is the "solution of groups" approach, wherein activity coefficients are found as sums of contributions from the structural groups that make up the molecules of a solution. The most widely applied such correlations are based on the UNIQUAC equation, and they have their origin in the UNIFAC method (**UNI**QUAC **F**unctional-group **A**ctivity **C**oefficients), proposed by Fredenslund, Jones, and Prausnitz [*AIChE J.* **21:** 1086–1099 (1975)], and given detailed treatment by Fredenslund, Gmehling, and Rasmussen [*Vapor-Liquid Equilibrium Using UNIFAC*, Elsevier, Amsterdam (1977)].

Subsequent development has led to a variety of applications, including liquid/liquid equilibria [Magnussen, Rasmussen, and Fredenslund, *Ind. Eng. Chem. Process Des. Dev.* **20:** 331–339 (1981)], solid/liquid equilibria [Anderson and Prausnitz, *Ind. Eng. Chem. Fundam.* **17:** 269–273 (1978)], solvent activities in polymer solutions [Oishi and Prausnitz, *Ind. Eng. Chem. Process Des. Dev.* **17:** 333–339 (1978)], vapor pressures of pure species [Jensen, Fredenslund, and Rasmussen, *Ind. Eng. Chem. Fundam.* **20:** 239–246 (1981)], gas solubilities [Sander, Skjold-Jørgensen, and Rasmussen, *Fluid Phase Equilib.* **11:** 105–126 (1983)], and excess enthalpies [Dang and Tassios, *Ind. Eng. Chem. Process Des. Dev.* **25:** 22–31 (1986)].

The range of applicability of the original UNIFAC model has been greatly extended and its reliability enhanced. Its most recent revision and extension is treated by Wittig, Lohmann, and Gmehling [*Ind. Eng. Chem. Res.* **42:** 183–188 (2003)], wherein are cited earlier pertinent papers. Because it is based on temperature-independent parameters, its application is largely restricted to 0 to 150°C.

Two modified versions of the UNIFAC model, based on temperature-dependent parameters, have come into use. Not only do they provide a wide temperature range of applicability, but also they allow correlation of various kinds of property data, including phase equilibria, infinite dilution activity coefficients, and excess properties. The most recent revision and extension of the modified UNIFAC (Dortmund) model is provided by Gmehling et al. [*Ind. Eng. Chem. Res.* **41:** 1678–1688 (2002)]. An extended UNIFAC model called KT-UNIFAC is described in detail by Kang et al. [*Ind. Eng. Chem. Res.* **41:** 3260–3273 (2003)]. Both papers contain extensive literature citations.

The UNIFAC model has also been combined with the predictive Soave-Redlich-Kwong (PSRK) equation of state. The procedure is most completely described (with background literature citations) by Horstmann et al. [*Fluid Phase Equilibria* **227:** 157–164 (2005)].

Because $\Sigma_i y_i = 1$, Eq. (4-307) may be summed over all species to yield

$$P = \sum_i x_i \gamma_i P_i^{\text{sat}} \tag{4-308}$$

Alternatively, Eq. (4-307) may be solved for x_i, in which case summing over all species yields

$$P = \frac{1}{\sum_i y_i/\gamma_i P_i^{\text{sat}}} \tag{4-309}$$

Example 3: Dew and Bubble Point Calculations As indicated by Example 2*a*, a binary system in vapor/liquid equilibrium has 2 degrees of freedom. Thus of the four phase rule variables T, P, x_1, and y_1, two must be fixed to allow calculation of the other two, regardless of the formulation of the equilibrium equations. Modified Raoult's law [Eq. (4-307)] may therefore be applied to the calculation of any pair of phase rule variables, given the other two.

The necessary vapor pressures and activity coefficients are supplied by data correlations. For the system acetone(1)/*n*-hexane(2), vapor pressures are given by Eq. (4-142), the Antoine equation:

$$\ln P_i^{\text{sat}}/\text{kPa} = A_i - \frac{B_i}{T/\text{K} + C_i} \qquad i = 1, 2 \tag{A}$$

with parameters

i	A_i	B_i	C_i
1	14.3145	2756.22	−45.090
2	13.8193	2696.04	−48.833

Activity coefficients are given by Eq. (4-274), the Wilson equation:

$$\ln \gamma_1 = -\ln(x_1 + x_2\Lambda_{12}) + x_2\lambda \tag{B}$$

$$\ln \gamma_2 = -\ln(x_2 + x_1\Lambda_{21}) - x_1\lambda \tag{C}$$

where $$\lambda \equiv \frac{\Lambda_{12}}{x_1 + x_2\Lambda_{12}} - \frac{\Lambda_{21}}{x_2 + x_1\Lambda_{21}}$$

By Eq. (4-279) $$\Lambda_{ij} = \frac{V_j}{V_i} \exp \frac{-a_{ij}}{RT} \qquad i \neq j$$

with parameters [Gmehling et al., *Vapor-Liquid Data Collection*, Chemistry Data Series, vol. 1, part 3, DECHEMA, Frankfurt/Main (1983)]

a_{12} cal mol^{-1}	a_{21} cal mol^{-1}	V_1 cm^3 mol^{-1}	V_2 cm^3 mol^{-1}
985.05	453.57	74.05	131.61

When T and x_1 are given, the calculation is direct, with final values for vapor pressures and activity coefficients given immediately by Eqs. (*A*), (*B*), and (*C*). In all other cases either T or x_1 or both are initially unknown, and calculations require trial or iteration.

a. BUBL P calculation: Find y_1 and P, given x_1 and T. Calculation here is direct. For $x_1 = 0.40$ and $T = 325.15$ K (52°C), Eqs. (*A*), (*B*), and (*C*) yield the values listed in the table on the following page. Equations (4-308) and (4-307) then become

$$P = x_1\gamma_1 P_1^{\text{sat}} + x_2\gamma_2 P_2^{\text{sat}} = (0.40)(1.8053)(87.616) + (0.60)(1.2869)(58.105) = 108.134 \text{ kPa}$$

$$y_1 = \frac{x_1\gamma_1 P_1^{\text{sat}}}{P} = \frac{(0.40)(1.8053)(87.616)}{108.134} = 0.5851$$

b. DEW P calculation: Find x_1 and P, given y_1 and T. With x_1 an unknown, the activity coefficients cannot be immediately calculated. However, an iteration scheme based on Eqs. (4-309) and (4-307) is readily devised, and is part of any solve routine of a software package. Starting values result from setting each $\gamma_i = 1$. For $y_1 = 0.4$ and $T = 325.15$ K (52°C), results are listed in the accompanying table.

c. BUBL T calculation: Find y_1 and T, given x_1 and P. With T unknown, neither the vapor pressures nor the activity coefficients can be initally calculated. An iteration scheme or a solve routine with starting values for the unknowns is required. Results for $x_1 = 0.32$ and $P = 80$ kPa are listed in the accompanying table.

d. DEW T calculation: Find x_1 and T, given y_1 and P. Again, an iteration scheme or a solve routine with starting values for the unknowns is required. For $y_1 = 0.60$ and $P = 101.33$ kPa, results are listed in the accompanying table.

e. Azeotrope calculations: As noted in Example 1*a*, only a single degree of freedom exists for this special case. The most sensitive quantity for identifying the azeotropic state is the *relative volatility*, defined as

$$\alpha_{12} \equiv \frac{y_1/x_1}{y_2/x_2}$$

Because $y_i = x_i$ for the azeotropic state, $\alpha_{12} = 1$. Substitution for the two ratios by Eq. (4-307) provides an equation for calculation of α_{12} from the thermodynamic functions:

$$\alpha_{12} = \frac{\gamma_1 P_1^{\text{sat}}}{\gamma_2 P_2^{\text{sat}}}$$

Because α_{12} is a monotonic function of x_1, the test of whether an azeotrope exists at a given T or P is provided by values of α_{12} in the limits of $x_1 = 0$ and $x_1 = 1$. If *both* values are either > 1 or < 1, no azeotrope exists. But if one value is < 1 and the other > 1, an azeotrope necessarily exists at the given T or P. Given T, the azeotropic composition and pressure is found by seeking the value of P that makes $x_1 = y_1$ or that makes $\alpha_{12} = 1$. Similarly, given P, one finds the azeotropic composition and temperature. Shown in the accompanying table are calculated azeotropic states for a temperature of 46°C and for a pressure of 101.33 kPa. At 46°C, the limiting values of α_{12} are 8.289 at $x_1 = 0$ and 0.223 at $x_1 = 1$.

Given values are italic; calculated results are boldface.

Data Reduction Correlations for G^E and the activity coefficients are based on VLE data taken at low to moderate pressures. Group-contribution methods, such as UNIFAC, depend for validity on parameters evaluated from a large base of such data. The process of finding a suitable analytic relation for g ($\equiv G^E/RT$) as a function of its independent variables T and x_1, thus producing a correlation of VLE data, is known as data reduction. Although g is in principle also a function of P, the dependence is so weak as to be universally and properly neglected. Given here is a brief description of the treatment of data taken for *binary* systems under *isothermal* conditions. A more comprehensive development is given by Van Ness [*J. Chem. Thermodyn.* **27:** 113–134 (1995); *Pure & Appl. Chem.* **67:** 859–872 (1995)].

Presumed in all that follows is the existence of an equation inherently capable of correlating values of G^E for the liquid phase as a function of x_1:

$$g \equiv G^E/RT = \mathcal{G}(x_1; \alpha, \beta, \ldots) \tag{4-310}$$

where α, β, etc., represent adjustable parameters.

The measured variables of binary VLE are x_1, y_1, T, and P. Experimental values of the activity coefficient of species i in the liquid are related to these variables by Eq. (4-303), written as

$$\gamma_i^* = \frac{y_i^* P^*}{x_i P_i^{sat}} \Phi_i \qquad i = 1, 2 \tag{4-311}$$

where Φ_i is given by Eq. (4-305) and the asterisks denote experimental values. A simple summability relation analogous to Eq. (4-252) defines an experimental value of g^*:

$$g^* \equiv x_1 \ln \gamma_1^* + x_2 \ln \gamma_2^* \tag{4-312}$$

Moreover, Eq. (4-263), the Gibbs-Duhem equation, may be written for experimental values in a binary system at constant T and P as

$$x_1 \frac{d \ln \gamma_1^*}{dx_1} + x_2 \frac{d \ln \gamma_2^*}{dx_1} = 0 \tag{4-313}$$

Because experimental measurements are subject to systematic error, sets of values of $\ln \gamma_1^*$ and $\ln \gamma_2^*$ may not satisfy, i.e., may not be *consistent* with, the Gibbs-Duhem equation. Thus Eq. (4-313) applied to sets of experimental values becomes a test of the thermodynamic consistency of the data, rather than a valid general relationship.

Values of g provided by the equation used to correlate the data, as represented by Eq. (4-310), are called *derived* values, and produce derived values of the activity coefficients by Eqs. (4-180) with $M \equiv g$:

$$\ln \gamma_1 = g + x_2 \frac{dg}{dx_1} \tag{4-314a}$$

$$\ln \gamma_2 = g - x_1 \frac{dg}{dx_1} \tag{4-314b}$$

These two equations combine to yield

$$\frac{dg}{dx_1} = \ln \frac{\gamma_1}{\gamma_2} \tag{4-315}$$

This equation is valid for *derived* property values. The corresponding *experimental* values are given by differentiation of Eq. (4-312):

$$\frac{dg^*}{dx_1} = x_1 \frac{d \ln \gamma_1^*}{dx_1} + \ln \gamma_1^* + x_2 \frac{d \ln \gamma_2^*}{dx_1} - \ln \gamma_2^*$$

or

$$\frac{dg^*}{dx_1} = \ln \frac{\gamma_1^*}{\gamma_2^*} + x_1 \frac{d \ln \gamma_1^*}{dx_1} + x_2 \frac{d \ln \gamma_2^*}{dx_1} \tag{4-316}$$

Subtraction of Eq. (4-316) from Eq. (4-315) gives

$$\frac{dg}{dx_1} - \frac{dg^*}{dx_1} = \ln \frac{\gamma_1}{\gamma_2} - \ln \frac{\gamma_1^*}{\gamma_2^*} - \left(x_1 \frac{d \ln \gamma_1^*}{dx_1} + x_2 \frac{d \ln \gamma_2^*}{dx_1} \right)$$

The differences between like terms represent *residuals* between derived and experimental values. Defining these residuals as

$$\delta g \equiv g - g^* \qquad \text{and} \qquad \delta \ln \frac{\gamma_1}{\gamma_2} \equiv \ln \frac{\gamma_1}{\gamma_2} - \ln \frac{\gamma_1^*}{\gamma_2^*}$$

puts this equation into the form

$$\frac{d\delta g}{dx_1} = \delta \ln \frac{\gamma_1}{\gamma_2} - \left(x_1 \frac{d \ln \gamma_1^*}{dx_1} + x_2 \frac{d \ln \gamma_2^*}{dx_1} \right)$$

If a data set is reduced so as to yield parameters—α, β, etc.—that make the δg residuals scatter about zero, then the derivative on the left is effectively zero, and the preceding equation becomes

$$\delta \ln \frac{\gamma_1}{\gamma_2} = x_1 \frac{d \ln \gamma_1^*}{dx_1} + x_2 \frac{d \ln \gamma_2^*}{dx_1} \tag{4-317}$$

The right side of this equation is the quantity required by Eq. (4-313), the Gibbs-Duhem equation, to be zero for consistent data. The residual on the left is therefore a direct measure of deviations from the Gibbs-Duhem equation. The extent to which values of this residual fail to scatter about zero measures the departure of the data from consistency with respect to this equation.

The data reduction procedure just described provides parameters in the correlating equation for g that make the δg residuals scatter about zero. This is usually accomplished by finding the parameters that minimize the sum of squares of the residuals. Once these parameters are found, they can be used for the calculation of derived values of both the pressure P and the vapor composition y_1. Equation (4-303) is solved for $y_i P$ and written for species 1 and for species 2. Adding the two equations gives

$$P = \frac{x_1 \gamma_1 P_1^{sat}}{\Phi_1} + \frac{x_2 \gamma_2 P_2^{sat}}{\Phi_2} \tag{4-318}$$

whence by Eq. (4-303),

$$y_1 = \frac{x_1 \gamma_1 P_1^{sat}}{\Phi_1 P} \tag{4-319}$$

These equations allow calculation of the *primary* residuals:

$$\delta P \equiv P - P^* \qquad \text{and} \qquad \delta y_1 \equiv y_1 - y_1^*$$

If the experimental values P^* and y_1^* are closely reproduced by the correlating equation for g, then these residuals, evaluated at the experimental values of x_1, scatter about zero. This is the result obtained when the data approach thermodynamic consistency. When they do not, these residuals fail to scatter about zero and the correlation for g does not properly reproduce the experimental values P^* and y_1^*.

Such a correlation is unnecessarily divergent. An alternative is to base data reduction on just the P-x_1 data subset; this is possible because the full P-x_1-y_1 data set includes redundant information. Assuming that the correlating equation is appropriate to the data, one merely searches for values of the parameters α, β, etc., that yield pressures by Eq. (4-318) that are as close as possible to the measured values. The usual procedure is to minimize the sum of squares of the residuals δP. Known as *Barker's method* [*Austral. J. Chem.* **6:** 207–210 (1953)], it provides the best possible fit of the experimental pressures. When experimental y_1^* values are not consistent with the P^*-x_1 data, Barker's method cannot lead to calculated y_1 values that closely match the experimental y_1^* values. With experimental error usually concentrated in the y_1^* values, the calculated y_1 values are likely to be more nearly correct. Because Barker's method requires only the P^*-x_1 data subset, the measurement of y_1^* values is not usually worth the extra effort, and the correlating parameters α, β, etc., are usually best determined without them. Hence, many P^*-x_1 data subsets appear in the literature; they are of course not subject to a test for consistency by the Gibbs-Duhem equation.

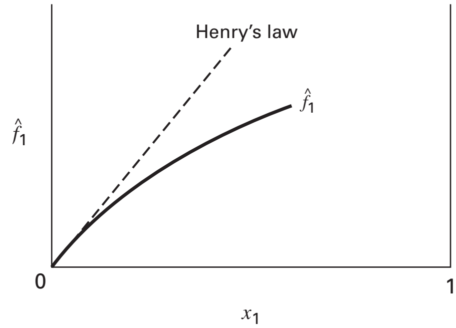

FIG. 4-7 Plot of solute fugacity $\hat{f}_1$ versus solute mole fraction. [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 555, McGraw-Hill, New York (2005).*]

The world's store of VLE data has been compiled by Gmehling et al. [*Vapor-Liquid Equilibrium Data Collection*, Chemistry Data Series, vol. 1, parts 1–8, DECHEMA, Frankfurt am Main (1979–1990)].

Solute/Solvent Systems The gamma/phi approach to VLE calculations presumes knowledge of the vapor pressure of each species at the temperature of interest. For certain binary systems species 1, designated the solute, is either unstable at the system temperature or is *supercritical* ($T > T_c$). Its vapor pressure cannot be measured, and its fugacity as a pure liquid at the system temperature f_1 cannot be calculated by Eq. (4-302).

Equations (4-303) and (4-304) are applicable to species 2, designated the solvent, but not to the solute, for which an alternative approach is required. Figure 4-7 shows a typical plot of the liquid-phase fugacity of the solute $\hat{f}_1$ versus its mole fraction x_1 at constant temperature. Since the curve representing $\hat{f}_1$ does not extend all the way to $x_1 = 1$, the location of f_1, the liquid-phase fugacity of pure species 1, is not established. The tangent line at the origin, representing *Henry's law*, provides alternative information. The slope of the tangent line is *Henry's constant*, defined as

$$k_1 \equiv \lim_{x_1 \to 0} \frac{\hat{f}_1}{x_1} \tag{4-320}$$

This is the definition of k_1 for temperature T and for a pressure equal to the vapor pressure of the pure solvent P_2^{sat}.

The activity coefficient of the solute at infinite dilution is

$$\lim_{x_1 \to 0} \gamma_1 = \lim_{x_1 \to 0} \frac{\hat{f}_1}{x_1 f_1} = \frac{1}{f_1} \lim_{x_1 \to 0} \frac{\hat{f}_1}{x_1}$$

In view of Eq. (4-320), this becomes $\gamma_1^\infty = k_1/f_1$, or

$$f_1 = \frac{k_1}{\gamma_1^\infty} \tag{4-321}$$

where γ_1^∞ represents the infinite dilution value of the activity coefficient of the solute. Because both k_1 and γ_1^∞ are evaluated at P_2^{sat}, this pressure also applies to f_1. However, the effect of P on a liquid-phase fugacity, given by a Poynting factor, is very small and for practical purposes may usually be neglected. The activity coefficient of the solute then becomes

$$\gamma_1 \equiv \frac{\hat{f}_1}{x_1 f_1} = \frac{y_1 P \hat{\phi}_1}{x_1 f_1} = \frac{y_1 P \hat{\phi}_1 \gamma_1^\infty}{x_1 k_1}$$

For the solute, this equation takes the place of Eqs. (4-303) and (4-304). Solution for y_1 gives

$$y_1 = \frac{x_1(\gamma_1/\gamma_1^\infty)k_1}{\hat{\phi}_1 P} \tag{4-322}$$

For the solvent, species 2, the analog of Eq. (4-319) is

$$y_2 = \frac{x_2 \gamma_2 P_2^{\text{sat}}}{\Phi_2 P} \tag{4-323}$$

Because $y_1 + y_2 = 1$, $\quad P = \dfrac{x_1(\gamma_1/\gamma_1^\infty)k_1}{\hat{\phi}_1} + \dfrac{x_2 \gamma_2 P_2^{\text{sat}}}{\Phi_2}$ (4-324)

The same correlation that provides for the evaluation of γ_1 also allows evaluation of γ_1^∞.

There remains the problem of finding Henry's constant from the available VLE data.

For equilibrium $\quad \hat{f}_1 \equiv \hat{f}_1^l = \hat{f}_1^v = y_1 P \hat{\phi}_1$

Division by x_1 gives $\quad \dfrac{\hat{f}_1}{x_1} = P\hat{\phi}_1 \dfrac{y_1}{x_1}$

Henry's constant is defined as the limit as $x_1 \to 0$ of the ratio on the left; therefore

$$k_1 = P_2^{\text{sat}} \hat{\phi}_1^\infty \lim_{x_1 \to 0} \frac{y_1}{x_1}$$

The limiting value of y_1/x_1 can be found by plotting y_1/x_1 versus x_1 and extrapolating to zero.

***K* Values, VLE, and Flash Calculations** A measure of the distribution of a chemical species between liquid and vapor phases is the K value, defined as the equilibrium ratio:

$$K_i \equiv \frac{y_i}{x_i} \tag{4-325}$$

It has no thermodynamic content, but may make for computational convenience through elimination of one set of mole fractions in favor of the other. It does characterize "lightness" of a constituent species. A "light" species, with $K > 1$, tends to concentrate in the vapor phase whereas a "heavy" species, with $K < 1$, tends to concentrate in the liquid phase.

The rigorous evaluation of a K value follows from Eq. (4-299):

$$K_i \equiv \frac{y_i}{x_i} = \frac{\gamma_i f_i}{\hat{\phi}_i P} \tag{4-326}$$

When Raoult's law applies, Eq. (4-326) reduces to $K_i = P_i^{\text{sat}}/P$. For modified Raoult's law, $K_i = \gamma_i P_i^{\text{sat}}/P$. With $K_i = y_i/x_i$, these are alternative expressions of Raoult's law and modified Raoult's law. Were Raoult's valid, K values could be correlated as functions of just T and P. However, Eq. (4-326) shows that they are in general functions of T, P, $\{x_i\}$, and $\{y_i\}$, making convenient and accurate correlation impossible. Those correlations that do exist are approximate and severely limited in application. The nomographs for K values of light hydrocarbons as functions of T and P, prepared by DePriester [*Chem. Eng. Progr. Symp. Ser. No. 7*, **49:** 1–43 (1953)], do allow for an *average* effect of composition, but their essential basis is Raoult's law.

The defining equation for K can be rearranged as $y_i = K_i x_i$. The sum $\Sigma_i y_i = 1$ then yields

$$\sum_i K_i x_i = 1 \tag{4-327}$$

With the alternative rearrangement $x_i = y_i/K_i$, the sum $\Sigma_i x_i = 1$ yields

$$\sum_i \frac{y_i}{K_i} = 1 \tag{4-328}$$

Thus for bubble point calculations, where the x_i are known, the problem is to find the set of K values that satisfies Eq. (4-327), whereas for dew point calculations, where the y_i are known, the problem is to find the set of K values that satisfies Eq. (4-328).

The *flash calculation* is a very common application of VLE. Considered here is the P, T flash, in which are calculated the quantities and compositions of the vapor and liquid phases in equilibrium at known T, P, and *overall* composition. This problem is determinate on the basis of Duhem's theorem: *For any closed system formed initally from*

given masses of prescribed chemical species, the equilibrium state is completely determined when any two independent variables are fixed. The independent variables are here T and P, and systems are formed from given masses of nonreacting chemical species.

For 1 mol of a system with *overall* composition represented by the set of mole fractions $\{z_i\}$, let $\mathcal{L}$ represent the molar fraction of the system that is liquid (mole fractions $\{x_i\}$) and let $\mathcal{V}$ represent the molar fraction that is vapor (mole fractions $\{y_i\}$). The material balance equations are

$$\mathcal{L} + \mathcal{V} = 1 \qquad \text{and} \qquad z_i = x_i\mathcal{L} + y_i\mathcal{V} \qquad i = 1, 2, \ldots, N$$

Combining these equations to eliminate $\mathcal{L}$ gives

$$z_i = x_i(1 - \mathcal{V}) + y_i\mathcal{V} \qquad i = 1,2, \ldots, N \tag{4-329}$$

Substitute $x_i = y_i/K_i$ and solve for y_i:

$$y_i = \frac{z_iK_i}{1 + \mathcal{V}(K_i - 1)} \qquad i = 1,2, \ldots, N$$

Because $\Sigma_i y_i = 1$, this equation, summed over all species, yields

$$\sum_i \frac{z_iK_i}{1 + \mathcal{V}(K_i - 1)} = 1 \tag{4-330}$$

The initial step in solving a P, T flash problem is to find the value of $\mathcal{V}$ which satisfies this equation. Note that $\mathcal{V} = 1$ is always a *trivial* solution.

Example 4: Flash Calculation The system of Example 3 has the overall composition $z_1 = 0.4000$ at $T = 325.15$ K and $P = 101.33$ kPa. Determine $\mathcal{V}$, x_1, and y_1.

The *BUBL P* and *DEW P* calculations at $T = 325.15$ K of Example 3*a* and 3*b* show that for $x_1 = z_1$, $P_{\text{bubl}} = 108.134$ kPa, and for $y_1 = z_1$, $P_{\text{dew}} = 87.939$ kPa. Because P here lies between these values, the system is in two-phase equilibrium, and a flash calculation is appropriate.

The modified Raoult's law K values are given by

$$K_1 = \frac{(\gamma_1)(P_1^{\text{sat}})}{P} \qquad \text{and} \qquad K_2 = \frac{(\gamma_2)(P_2^{\text{sat}})}{P}$$

Equation (4-329) may be solved for $\mathcal{V}$: $\quad \mathcal{V} = \dfrac{z_1 - x_1}{y_1 - x_1}$

Equation (4-330) here becomes

$$\frac{(z_1)(K_1)}{1 + \mathcal{V}(K_1 - 1)} + \frac{(z_2)(K_2)}{1 + \mathcal{V}(K_2 - 1)} = 1$$

A trial calculation illustrates the nature of the solution. Vapor pressures are taken from Example 3*a* or 3*b*; a trial value of x_1 then allows calculation of γ_1 and γ_2 by Eqs. (*B*) and (*C*) of Example 3. The values of K_1, K_2, and $\mathcal{V}$ that result are substituted into the summation equation. In the unlikely event that the sum is indeed unity, the chosen value of x_1 is correct. If not, then successive trials easily lead to this value. Note that the trivial solution giving $\mathcal{V} = 1$ must be avoided. More elegant solution procedures can of course be employed. The answers are

$$x_1 = 0.2373 \quad y_1 = 0.5190 \quad \mathcal{V} = 0.5775$$

with $\quad \gamma_1 = 2.5297 \quad \gamma_2 = 1.0997 \quad K_1 = 2.1873 \quad K_2 = 0.6306$

Equation-of-State Approach Although the gamma/phi approach to VLE is in principle generally applicable to systems comprised of subcritical species, in practice it has found use primarily where pressures are no more than a few bars. Moreover, it is most satisfactory for correlation of constant-temperature data. A temperature dependence for the parameters in expressions for G^E is included only for the local composition equations, and it is at best approximate.

A generally applicable alternative to the gamma/phi approach results when both the liquid and vapor phases are described by the same equation of state. The defining equation for the fugacity coefficient, Eq. (4-204), may be applied to each phase:

$$\text{Liquid:} \quad \hat{f}_i^l = \hat{\phi}_i^l x_i P \qquad \text{Vapor:} \quad \hat{f}_i^v = \hat{\phi}_i^v y_i P$$

By Eq. (4-298),

$$x_i\hat{\phi}_i^l = y_i\hat{\phi}_i^v \quad i = 1, 2, \ldots, N \tag{4-331}$$

This introduces compositions x_i and y_i into the equilibrium equations, but neither is explicit, because the $\hat{\phi}_i$ are functions, not only of T and P, but of composition. Thus, Eq. (4-331) represents N complex relationships connecting T, P, $\{x_i\}$, and $\{y_i\}$.

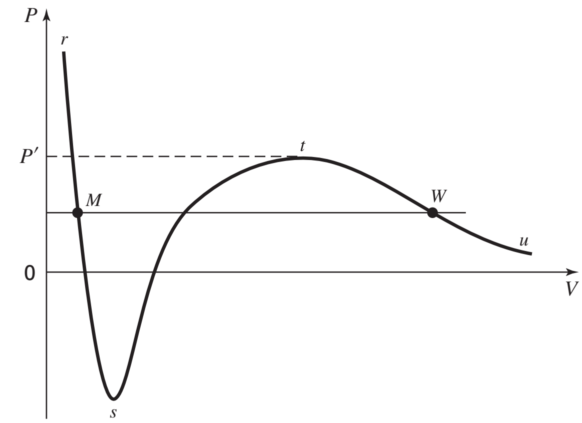

FIG. 4-8 A subcritical isotherm on a *PV* diagram for a pure fluid. [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 557, McGraw-Hill, New York (2005).*]

Two widely used cubic equations of state appropriate for VLE calculations, both special cases of Eq. (4-100) [with Eqs. (4-101) and (4-102)], are the Soave-Redlich-Kwong (SRK) equation and the Peng-Robinson (PR) equation. The present treatment is applicable to both. The pure numbers ϵ, σ, Ψ, and Ω and expressions for $\alpha(T_{r_i})$ specific to these equations are listed in Table 4-2. The associated expression for $\hat{\phi}_i$ is given by Eq. (4-246).

The simplest application of equations of state in vapor/liquid equilibrium is to the calculation of vapor pressures P_i^{sat} of pure liquids. Vapor pressures can of course be measured, but values are also implicit in cubic equations of state.

A subcritical *PV* isotherm, generated by a cubic equation of state, is shown in Fig. 4-8. Three segments are evident. The very steep one on the left (*rs*) is characteristic of liquids. Note that as $P \to \infty, V \to b$, where b is a constant in the cubic equation. The gently sloping segment on the right (*tu*) is characteristic of vapors; here $P \to 0$ as $V \to \infty$. The middle segment (*st*), with both a minimum (note $P < 0$) and a maximum, provides a transition from liquid to vapor, but has no physical meaning. The actual transition occurs along a horizontal line, such as connects points M and W.

For pure species i, Eq. (4-331) reduces to $\phi_i^v = \phi_i^l$, which may be written as

$$\ln \phi_i^v = \ln \phi_i^l \tag{4-332}$$

For given T, line MW lies at the vapor pressure P_i^{sat} if and only if the fugacity coefficients for points M and W satisfy Eq. (4-332). These points then represent *saturated* liquid and vapor phases in equilibrium at temperature T.

The fugacity coefficients in Eq. (4-332) are given by Eq. (4-245):

$$\ln \phi_i^p = Z_i^p - 1 - \ln(Z_i^p - \beta_i) - q_i I_i^p \qquad p = l, v \tag{4-333}$$

Expressions for Z_i^v and Z_i^l come from Eqs. (4-104):

$$Z_i^v = 1 + \beta_i - q_i\beta_i \frac{Z_i^v - \beta_i}{(Z_i^v + \epsilon\beta_i)(Z_i^v + \sigma\beta_i)} \tag{4-334}$$

$$Z_i^l = \beta_i + (Z_i^l + \epsilon\beta_i)(Z_i^l + \sigma\beta_i)\left(\frac{1 + \beta_i - Z_i^l}{q_i\beta_i}\right) \tag{4-335}$$

and I_i^p comes from Eq. (4-112):

$$I_i^p = \frac{1}{\sigma - \epsilon} \ln \frac{Z_i^p + \sigma\beta_i}{Z_i^p + \epsilon\beta_i} \qquad p = l, v \tag{4-336}$$

The equation-of-state parameters are independent of phase. As defined by Eq. (4-105), β_i is a function of P and here becomes

$$\beta_i \equiv \frac{b_i P_i^{sat}}{RT} \tag{4-337}$$

The remaining equation-of-state parameters, given by Eqs. (4-101), (4-102), and (4-106), are functions of T only and are written here as

$$a_i(T) = \psi \frac{\alpha(T_{r_i}) R^2 T_{c_i}^2}{P_{c_i}} \tag{4-338}$$

$$b_i = \Omega \frac{RT_{c_i}}{P_{c_i}} \tag{4-339}$$

$$q_i \equiv \frac{a_i(T)}{b_i RT} \tag{4-340}$$

The eight equations (4-332) through (4-337) may be solved for the eight unknowns P_i^{sat}, β_i, Z_i^l, Z_i^v, I_i^l, I_i^v, $\ln \phi_i^l$, and $\ln \phi_i^v$.

Perhaps more useful is the reverse calculation whereby an equation-of-state parameter is evaluated from a known vapor pressure. Thus, Eqs. (4-332) and (4-333) may be combined and solved for q_i, yielding

$$q_i = \frac{Z_i^v - Z_i^l + \ln[(Z_i^l - \beta_i)/(Z_i^v - \beta_i)]}{I_i^v - I_i^l} \tag{4-341}$$

Expressions for Z_i^l, Z_i^v, I_i^l, I_i^v, and β_i are given by Eqs. (4-334) through (4-337). Because Z_i^l and Z_i^v depend on q_i, an iterative procedure is indicated, with a starting value for q_i from a generalized correlation as given by Eqs. (4-338), (4-339), and (4-340).

For mixtures the presumption is that the equation of state has exactly the same form as when written for pure species. Equations (4-104) are therefore applicable, with parameters β and q given by Eqs. (4-105) and (4-106). Here, these parameters, and therefore b and $a(T)$, are *functions of composition*. Liquid and vapor mixtures in equilibrium in general have different compositions. The *PV* isotherms generated by an equation of state for these different compositions are represented in Fig. 4-9 by two similar lines: the solid line for the liquid-phase composition and the dashed line for the vapor-phase composition. They are displaced from each other because the equation-of-state parameters are different for the two compositions.

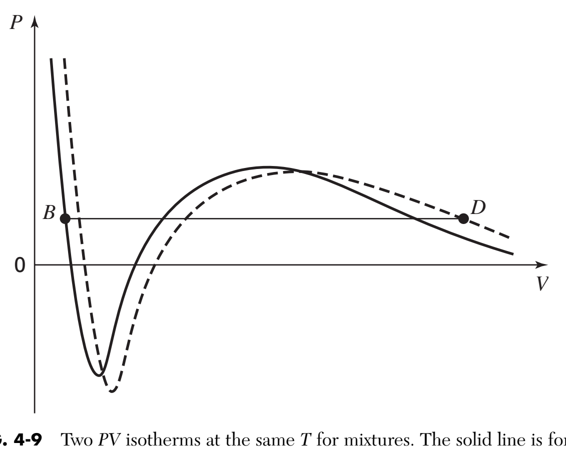

FIG. 4-9 Two *PV* isotherms at the same *T* for mixtures. The solid line is for a liquid-phase composition; the dashed line is for a vapor-phase composition. Point *B* represents a bubble point with the liquid-phase composition; point *D* represents a dew point with the vapor-phase composition. When these points lie at the same *P* (as shown), they represent phases in equilibrium. [*Smith, Van Ness, and Abbott,* Introduction to Chemical Engineering Thermodynamics, *7th ed., p. 560, McGraw-Hill, New York (2005).*]

Each line includes three *segments* as described for the isotherm of Fig. 4-8: the leftmost segment representing a liquid phase and the rightmost segment, a vapor phase, *both with the same composition*. Each left segment contains a bubble point (saturated liquid), and each right segment contains a dew point (saturated vapor). Because these points for a given line are for the same composition, they do not represent phases in equilibrium and do not lie at the same pressure. Shown in Fig. 4-9 is a bubble point B on the solid line and a dew point D on the dashed line. Because they lie at the same P, they represent phases in equilibrium, and the lines are characterized by the liquid and vapor compositions.

For a *BUBL P* calculation, the temperature and the liquid composition are known, and this fixes the location of the *PV* isotherm for the composition of the liquid phase (solid line). The problem then is to locate a second (dashed) line for a vapor composition such that the line contains a dew point D on its vapor segment that lies at the pressure of the bubble point B on the liquid segment of the solid line. This pressure is the phase equilibrium pressure, and the composition for the dashed line is that of the equilibrium vapor. This equilibrium condition is shown by Fig. 4-9.

In the absence of a theory to prescribe the composition dependence of parameters for cubic equations of state, empirical *mixing rules* are used to relate mixture parameters to pure-species parameters. The simplest realistic expressions are a linear mixing rule for parameter b and a quadratic mixing rule for parameter a, as shown by Eqs. (4-113) and (4-114). A common combining rule is given by Eq. (4-115). The general mole fraction variable x_i is used here because application is to both liquid and vapor mixtures. These equations, known as van der Waals prescriptions, provide for the evaluation of mixture parameters solely from parameters for the pure constituent species. They find application primarily for mixtures comprised of simple and chemically similar molecules.

Useful in the application of cubic equations of state to mixtures are *partial* equation-of-state parameters. For the parameters of the generic cubic, represented by Eqs. (4-104), (4-105), and (4-106), the definitions are

$$\bar{a}_i \equiv \left[\frac{\partial(na)}{\partial n_i}\right]_{T,n_j} \tag{4-342}$$

$$\bar{b}_i \equiv \left[\frac{\partial(nb)}{\partial n_i}\right]_{T,n_j} \tag{4-343}$$

$$\bar{q}_i \equiv \left[\frac{\partial(nq)}{\partial n_i}\right]_{T,n_j} \tag{4-344}$$

These are general equations, valid regardless of the particular mixing or combining rules adopted for the composition dependence of mixture parameters.

Parameter q is defined in relation to parameters a and b by Eq. (4-106). Thus,

$$nq = \frac{n(na)}{RT(nb)}$$

whence

$$\bar{q}_i \equiv \left[\frac{\partial(nq)}{\partial n_i}\right]_{T,n_j} = q\left(1 + \frac{\bar{a}_i}{a} - \frac{\bar{b}_i}{b}\right) \tag{4-345}$$

Any two of the three partial parameters form an independent pair, and any one of them can be found from the other two. Because q, a, and b are not linearly related, $\bar{q}_i \neq \bar{a}_i/\bar{b}_i RT$.

Values of $\hat{\phi}_i^l$ and $\hat{\phi}_i^v$ as given by Eq. (4-246) are implicit in an equation of state and with Eq. (4-331) allow calculation of *mixture* VLE. Although more complex, the same basic principle applies as for pure-species VLE. With $\hat{\phi}_i^l$ a function of T, P, and $\{x_i\}$, and $\hat{\phi}_i^V$ a function of T, P, and $\{y_i\}$, Eq. (4-331) represents N relations among the $2N$ variables: T, P, $(N-1)$ x_is, and $(N-1)$ y_is. Thus, specification of N of these variables, usually either T or P *and* either the liquid- or vapor-phase composition, allows solution for the remaining N variables by *BUBL P*, *DEW P*, *BUBL T*, and *DEW T* calculations.

Because of limitations inherent in empirical mixing and combining rules, such as those given by Eqs. (4-113) through (4-115), the equation-of-state approach has found primary application to systems exhibiting modest deviations from ideal solution behavior in the liquid phase, e.g., to systems containing hydrocarbons and cryogenic fluids. However, since 1990, extensive research has been devoted to developing mixing rules that incorporate the excess Gibbs energy or activity coefficient data available for many systems. The extensive literature on this subject is reviewed by Valderrama [*Ind. Eng. Chem. Res.* **42:** 1603–1618 (2003)] and by Twu, Sim, and Tassone [*Chem. Eng. Progress* **98:**(11): 58–65 (Nov. 2002)].

The idea here is to exploit the connection between fugacity coefficients and activity coefficients provided by their definitions:

$$\gamma_i \equiv \frac{\hat{f}_i}{x_i f_i} = \frac{\hat{f}_i/x_i P}{f_i/P} = \frac{\hat{\phi}_i}{\phi_i}$$

Therefore,

$$\ln \gamma_i = \ln \hat{\phi}_i - \ln \phi_i \tag{4-346}$$

Because γ_i is a liquid-phase property, this equation is written for the liquid phase. Substituting for $\ln \hat{\phi}_i$ and $\ln \phi_i$ by Eqs. (4-245) and Eq. (4-246) gives

$$\ln \gamma_i = \frac{b_i}{b}(Z-1) - Z_i + 1 - \ln\frac{Z-\beta}{Z_i-\beta_i} - \bar{q}_i I + q_i I_i$$

Symbols without subscripts are mixture properties. Solution for $\bar{q}_i$ yields

$$\bar{q}_i = \frac{1}{I}\left[1 - Z_i + \frac{b_i}{b}(Z-1) - \ln\frac{Z-\beta}{Z_i-\beta_i} + q_i I_i - \ln \gamma_i\right] \tag{4-347}$$

Because $\bar{q}_i$ is a partial property, the summability equation provides an exact mixing rule:

$$q = \sum_i x_i \bar{q}_i \tag{4-348}$$

Application of this equation in the solution of VLE problems is illustrated by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 569–572, McGraw-Hill, New York (2005)].

Extrapolation of Data with Temperature Liquid-phase excess-property data for binary systems at near-ambient temperatures appear in the literature. They provide for the extrapolation of G^E correlations with temperature. The key relations are Eq. (4-250), written as

$$d\left(\frac{G^E}{RT}\right) = -\frac{H^E}{RT^2}dT \quad \text{constant } P, x$$

and the excess-property analog of Eq. (4-26):

$$dH^E = C_P^E\, dT \quad \text{constant } P, x$$

Integration of the first equation from T_0 to T gives

$$\frac{G^E}{RT} = \left(\frac{G^E}{RT}\right)_{T_0} - \int_{T_0}^{T}\frac{H^E}{RT^2}dT \tag{4-349}$$

Integration of the second equation from T_1 to T yields

$$H^E = H_1^E + \int_{T_1}^{T} C_P^E\, dT \tag{4-350}$$

In addition,

$$dC_P^E = \left(\frac{\partial C_P^E}{\partial T}\right)_{P,x} dT$$

Integrate from T_2 to T:

$$C_P^E = C_{P_2}^E + \int_{T_2}^{T}\left(\frac{\partial C_P^E}{\partial T}\right)_{P,x} dT$$

Combining this equation with Eqs. (4-349) and (4-350) leads to

$$\frac{G^E}{RT} = \left(\frac{G^E}{RT}\right)_{T_0} - \left(\frac{H^E}{RT}\right)_{T_1}\left(\frac{T}{T_0}-1\right)\frac{T_1}{T} - \frac{C_{P_2}^E}{R}\left[\ln\frac{T}{T_0} - \left(\frac{T}{T_0}-1\right)\frac{T_1}{T}\right] - I \tag{4-351}$$

where

$$I \equiv \int_{T_0}^{T}\frac{1}{RT^2}\int_{T_1}^{T}\int_{T_2}^{T}\left(\frac{\partial C_P^E}{\partial T}\right)_{P,x} dT\, dT\, dT$$

This general equation employs excess Gibbs energy data at temperature T_0, excess enthalpy (heat-of-mixing) data at T_1, and excess heat capacity data at T_2. Integral I depends on the temperature dependence of C_P^E. Excess heat capacity data are uncommon, and the T dependence is rarely known. Assuming C_P^E independent of T makes the integral zero, and the closer T_0 and T_1 are to T, the less the influence of this assumption. When no information is available for C_P^E and excess enthalpy data are available at only a single temperature, C_P^E must be assumed zero. In this case only the first two terms on the right side of Eq. (4-351) are retained, and it more rapidly becomes imprecise as T increases.

For application of Eq. (4-351) to binary systems at *infinite dilution* of one of the constituent species, it is divided by the product x_1x_2.

$$\frac{G^E}{x_1x_2RT} = \left(\frac{G^E}{x_1x_2RT}\right)_{T_0} - \left(\frac{H^E}{x_1x_2RT}\right)_{T_1}\left(\frac{T}{T_0}-1\right)\frac{T_1}{T} - \frac{C_P^E}{x_1x_2R}\left[\ln\frac{T}{T_0} - \left(\frac{T}{T_0}-1\right)\frac{T_1}{T}\right]$$

The assumption here is that C_P^E is independent of T, making $I = 0$. As shown by Smith, Van Ness and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 437, McGraw-Hill, New York (2005)],

$$\left(\frac{G^E}{x_1x_2RT}\right)_{x_i=0} \equiv \ln \gamma_i^\infty$$

The preceding equation may therefore be written as

$$\ln \gamma_i^\infty = (\ln \gamma_i^\infty)_{T_0} - \left(\frac{H^E}{x_1x_2RT}\right)_{T_1, x_i=0}\left(\frac{T}{T_0}-1\right)\frac{T_1}{T} - \left(\frac{C_P^E}{x_1x_2R}\right)_{x_i=0}\left[\ln\frac{T}{T_0} - \left(\frac{T}{T_0}-1\right)\frac{T_1}{T}\right] \tag{4-352}$$

Example 5: VLE at Several Temperatures For the methanol(1)/acetone(2) system at a base temperature of T_0 = 323.15 K (50°C), both VLE data [Van Ness and Abbott, *Int. DATA Ser., Ser. A, Sel. Data Mixtures*, **1978:** 67 (1978)] and excess enthalpy data [Morris et al., *J. Chem. Eng. Data* **20:** 403–405 (1975)] are available. The VLE data are well correlated by the Margules equations. As noted in connection with Eq. (4-270), parameters A_{12} and A_{21} relate directly to infinite dilution values of the activity coefficients. Thus, we have from the VLE data at 323.15 K:

$$A_{12} = \ln \gamma_1^\infty = 0.6281 \quad \text{and} \quad A_{21} = \ln \gamma_2^\infty = 0.6557$$

These values allow calculation of equilibrium pressures through Eqs. (4-270) and (4-308) for comparison with the measured pressures of the data set. Values of P_i^{sat} required in Eq. (4-308) are the measured values reported with the data set. The root-mean-square (rms) value of the pressure differences is given in Table 4-7 as 0.08 kPa, thus confirming the suitability of the Margules equation for this system. Vapor-phase mole fractions were not reported; hence no value can be given for rms δy_1.

Experimental VLE data at 372.8 and 397.7 K are given by Wilsak et al. [*Fluid Phase Equilib.* **28:** 13–37 (1986)]. Values of $\ln \gamma_i^\infty$ and hence of the Margules parameters for these higher temperatures are found from Eq. (4-352) with $C_P^E = 0$. The required excess enthalpy values at T_0 are

$$\left(\frac{H^E}{x_1x_2RT}\right)_{T_0, x_1=0} = 1.3636 \quad \text{and} \quad \left(\frac{H^E}{x_1x_2RT}\right)_{T_0, x_2=0} = 1.0362$$

TABLE 4-7 VLE Results for Methanol(1)/Acetone(2)

T, K	$A_{12} = \ln \gamma_1^\infty$	$A_{21} = \ln \gamma_2^\infty$	RMS δP/kPa	RMS % δP	RMS δy_1
323.15	0.6281	0.6557	0.08	0.12	
372.8	0.4465	0.5177	0.85	0.22	0.004
	(0.4607)	(0.5271)	(0.83)		(0.006)
397.7	0.3725	0.4615	2.46	0.32	0.014
	(0.3764)	(0.4640)	(1.39)		(0.013)

Results of calculations with the Margules equations are displayed as the primary entries at each temperature in Table 4-7. The values in parentheses are from the gamma/phi approach as reported in the papers cited.

Results for the higher temperatures indicate the quality of predictions based only on vapor-pressure data for the pure species and on mixture data at 323.15 K. Extrapolations based on the same data to still higher temperatures can be expected to become progressively less accurate.

Only the Wilson, NRTL, and UNIQUAC equations are suited to the treatment of multicomponent systems. For such systems, the parameters are determined for pairs of species exactly as for a binary system.

LIQUID/LIQUID AND VAPOR/LIQUID/LIQUID EQUILIBRIA

Equation (4-295) is the basis for both liquid/liquid equilibria (LLE) and vapor/liquid/liquid equilibria (VLLE). Thus for LLE with superscripts α and β denoting the two phases, Eq. (4-295) is written as

$$\hat{f}_i^\alpha = \hat{f}_i^\beta \qquad i = 1, 2, \ldots, N \tag{4-353}$$

Eliminating fugacities in favor of activity coefficients gives

$$x_i^\alpha \gamma_i^\alpha = x_i^\beta \gamma_i^\beta \qquad i = 1, 2, \ldots, N \tag{4-354}$$

For most LLE applications, the effect of pressure on the γ_i can be ignored, and Eq. (4-354) then constitutes a set of N equations relating equilibrium compositions to one another and to temperature. For a given temperature, solution of these equations requires a single expression for the composition dependence of G^E suitable for both liquid phases. Not all expressions for G^E suffice, even in principle, because some cannot represent liquid/liquid phase splitting. The UNIQUAC equation is suitable, and therefore prediction is possible by UNIFAC models. A special table of parameters for LLE calculations is given by Magnussen et al. [*Ind. Eng. Chem. Process Des. Dev.* **20:** 331–339 (1981)].

A comprehensive treatment of LLE is given by Sorensen et al. [*Fluid Phase Equilib.* **2:** 297–309 (1979); **3:** 47–82 (1979); **4:** 151–163 (1980)]. Data for LLE are collected in a three-part set compiled by Sorensen and Arlt [*Liquid-Liquid Equilibrium Data Collection*, Chemistry Data Series, vol. 5, parts 1–3, DECHEMA, Frankfurt am Main (1979–1980)].

For vapor/liquid/liquid equilibria, Eq. (4-295) becomes

$$\hat{f}_i^\alpha = \hat{f}_i^\beta = \hat{f}_i^v \qquad i = 1, 2, \ldots, N \tag{4-355}$$

where α and β designate the two liquid phases. With activity coefficients applied to the liquid phases and fugacity coefficients to the vapor phase, the $2N$ equilibrium equations for subcritical VLLE are

$$\left.\begin{aligned} x_i^\alpha \gamma_i^\alpha f_i^\alpha &= y_i \hat{\phi}_i P \\ x_i^\beta \gamma_i^\beta f_i^\beta &= y_i \hat{\phi}_i P \end{aligned}\right\} \quad \text{all } i \tag{4-356}$$

As for LLE, an expression for G^E capable of representing liquid/liquid phase splitting is required; as for VLE, a vapor-phase equation of state for computing the $\hat{\phi}_i$ is also needed.

CHEMICAL REACTION STOICHIOMETRY

For a phase in which a chemical reaction occurs according to the equation

$$|\nu_1|A_1 + |\nu_2|A_2 + \cdots \to |\nu_3|A_3 + |\nu_4|A_4 + \cdots$$

the $|\nu_i|$ are stoichiometric coefficients and the A_i stand for chemical formulas. The ν_i themselves are called stoichiometric numbers, and associated with them is a sign convention such that the value is positive for a product and negative for a reactant. More generally, for a system containing N chemical species, any or all of which can participate in r chemical reactions, the reactions are represented by the equations

$$0 = \sum_i \nu_{i,j} A_i \quad j = \text{I, II}, \ldots, r \tag{4-357}$$

where $$\text{sign}(\nu_{i,j}) = \begin{cases} - & \text{for a reactant species} \\ + & \text{for a product species} \end{cases}$$

If species i does not participate in reaction j, then $v_{i,j} = 0$.

The stoichiometric numbers provide relations among the changes in mole numbers of chemical species which occur as the result of chemical reaction. Thus, for reaction j

$$\frac{\Delta n_{1,j}}{\nu_{1,j}} = \frac{\Delta n_{2,j}}{\nu_{2,j}} = \cdots = \frac{\Delta n_{N,j}}{\nu_{N,j}} \tag{4-358}$$

All these terms are equal, and they can be equated to the change in a single quantity ε_j, called the *reaction coordinate* for reaction j, thereby giving

$$\Delta n_{i,j} = \nu_{i,j} \Delta\varepsilon_j \quad \begin{aligned} i &= 1, 2, \ldots, N \\ j &= \text{I, II}, \ldots, r \end{aligned} \tag{4-359}$$

Because the total change in mole number Δn_i is just the sum of the changes Δn_{ij} resulting from the various reactions,

$$\Delta n_i = \sum_j \Delta n_{ij} = \sum_j \nu_{ij} \Delta\varepsilon_j \qquad i = 1, 2, \ldots, N \tag{4-360}$$

If the initial number of moles of species i is n_{i_0} and if the convention is adopted that $\varepsilon_j = 0$ for each reaction in this initial state, then

$$n_i = n_{i_0} + \sum_j \nu_{ij} \varepsilon_j \qquad i = 1, 2, \ldots, N \tag{4-361}$$

Equation (4-361) is the basic expression of material balance for a closed system in which r chemical reactions occur. It shows for a reacting system that at most r mole-number-related quantities ε_j are capable of independent variation. It is not an equilibrium relation, but merely an accounting scheme, valid for tracking the progress of the reactions to arbitrary levels of conversion. The reaction coordinate has units of moles. A change in ε_j of 1 mol signifies a *mole of reaction*, meaning that reaction j has proceeded to such an extent that the change in mole number of each reactant and product is equal to its stoichiometric number.

CHEMICAL REACTION EQUILIBRIA

The general criterion of chemical reaction equilibria is given by Eq. (4-296). For a system in which just a single reaction occurrs, Eq. (4-361) becomes

$$n_i = n_{i_0} + \nu_i\varepsilon \quad \text{whence} \quad dn_i = \nu_i \, d\varepsilon$$

Substitution for dn_i in Eq. (4-296) leads to

$$\sum_i \nu_i \mu_i = 0 \tag{4-362}$$

Generalization of this result to multiple reactions produces

$$\sum_i \nu_{i,j} \mu_i = 0 \qquad j = \text{I, II}, \ldots, r \tag{4-363}$$

Standard Property Changes of Reaction For the reaction

$$aA + bB \to lL + mM$$

a *standard* property change is defined as the property change resulting when a mol of A and b mol of B in their *standard states at temperature*

T react to form l mol of L and m mol of M in their *standard states also at temperature T*. A *standard state* of species i is its real or hypothetical state as a pure species *at temperature T* and at a standard state pressure $P°$. The standard property change of reaction j is given the symbol $\Delta M_j°$, and its general mathematical definition is

$$\Delta M_j° \equiv \sum_i \nu_{i,j} M_i° \tag{4-364}$$

For species present as gases in the actual reactive system, the standard state is the pure *ideal gas* at pressure $P°$. For liquids and solids, it is usually the state of pure real liquid or solid at $P°$. The standard state pressure $P°$ is fixed at 100 kPa. Note that the standard states may represent different physical states for different species; any or all the species may be gases, liquids, or solids.

The most commonly used standard property changes of reaction are

$$\Delta G_j° \equiv \sum_i \nu_{i,j} G_i° = \sum_i \nu_{i,j} \mu_i° \tag{4-365}$$

$$\Delta H_j° \equiv \sum_i \nu_{i,j} H_i° \tag{4-366}$$

$$\Delta C_{P_j}° \equiv \sum_i \nu_{i,j} C_{P_i}° \tag{4-367}$$

The standard Gibbs energy change of reaction $\Delta G_j°$ is used in the calculation of equilibrium compositions. The standard heat of reaction $\Delta H_j°$ is used in the calculation of the heat effects of chemical reaction, and the standard heat capacity change of reaction is used for extrapolating $\Delta H_j°$ and $\Delta G_j°$ with T. Numerical values for $\Delta H_j°$ and $\Delta G_j°$ are computed from tabulated formation data, and $\Delta C_{P_j}°$ is determined from empirical expressions for the T dependence of the $C_{P_i}°$ [see, e.g., Eq. (4-52)].

Equilibrium Constants For practical application, Eq. (4-363) must be reformulated. The initial step is elimination of the μ_i in favor of fugacities. Equation (4-199) for species i in its standard state is subtracted from Eq. (4-202) for species i in the equilibrium mixture, giving

$$\mu_i = G_i° + RT \ln \hat{a}_i \tag{4-368}$$

where by definition $\hat{a}_i \equiv \hat{f}_i/f_i°$ and is called an *activity*. Substitution of this equation into Eq. (4-364) yields, upon rearrangement,

$$\sum_i [\nu_{i,j}(G_i° + RT \ln \hat{a}_i)] = 0$$

or

$$\sum_i \nu_{i,j} G_i° + RT \sum_i \ln \hat{a}_i^{\nu_{i,j}} = 0$$

or

$$\ln \prod_i \hat{a}_i^{\nu_{i,j}} = \frac{-\sum_i \nu_{i,j} G_i°}{RT}$$

The right side of this equation is a function of temperature only for given reactions and given standard states. Convenience suggests setting it equal to $\ln K_j$, whence

$$\prod_i \hat{a}_i^{\nu_{i,j}} = K_j \qquad \text{all } j \tag{4-369}$$

where, by definition,

$$K_j \equiv \exp\left(\frac{-\Delta G_j°}{RT}\right) \tag{4-370}$$

Quantity K_j is the chemical reaction equilibrium constant for reaction j, and $\Delta G_j°$ is the corresponding standard Gibbs energy change of reaction [see Eq. (4-365)]. Although called a "constant," K_j is a function of T, but only of T.

The activities in Eq. (4-369) provide the connection between the *equilibrium* states of interest and the *standard* states of the constituent species, for which data are presumed available. The standard states are always at the equilibrium temperature. Although the standard state need not be the same for all species, for a *particular* species it must be the state represented by both $G_i°$ and the $f_i°$ upon which activity $\hat{a}_i$ is based.

The application of Eq. (4-369) requires explicit introduction of composition variables. For gas-phase reactions this is accomplished through the fugacity coefficient

$$\hat{a}_i \equiv \frac{\hat{f}_i}{f_i°} = \frac{y_i \hat{\phi}_i P}{f_i°}$$

However, the standard state for gases is the ideal gas state at the standard state pressure, for which $f_i° = P°$. Therefore,

$$\hat{a}_i = \frac{y_i \hat{\phi}_i P}{P°}$$

and Eq. (4-369) becomes

$$\prod_i (y_i \hat{\phi}_i)^{\nu_{i,j}} \left(\frac{P}{P°}\right)^{\nu_j} = K_j \qquad \text{all } j \tag{4-371}$$

where $\nu_j \equiv \Sigma_i \nu_{i,j}$ and $P°$ is the standard state pressure of 100 kPa, expressed in the same units used for P. The y_i's may be eliminated in favor of equilibrium values of the reaction coordinates ε_j (see Example 6). Then, for fixed temperature Eqs. (4-371) relate the ε_j to P. In principle, specification of the pressure allows solution for the ε_j. However, the problem may be complicated by the dependence of the $\hat{\phi}_i$ on composition, i.e., on the ε_j. If the equilibrium mixture is assumed an ideal solution, then [Eq. (4-218)] each $\hat{\phi}_i$ becomes ϕ_i, the fugacity coefficient of pure species i at the mixture T and P. This quantity does not depend on composition and may be determined from experimental data, from a generalized correlation, or from an equation of state.

An important special case of Eq. (4-371) results for gas-phase reactions when the phase is assumed an ideal gas. In this event $\hat{\phi}_i = 1$, and

$$\prod_i (y_i)^{\nu_{i,j}} \left(\frac{P}{P°}\right)^{\nu_j} = K_j \qquad \text{all } j \tag{4-372}$$

In the general case the evaluation of the $\hat{\phi}_i$ requires an iterative process. An initial step is to set each $\hat{\phi}_i$ equal to unity and to solve the problem by Eq. (4-372). This provides a set of y_i values, allowing evaluation of the $\hat{\phi}_i$ by, for example, Eq. (4-243) or (4-246). Equation (4-371) can then be solved for a new set of y_i values, with the process continued to convergence.

For liquid-phase reactions, Eq. (4-369) is modified by introduction of the activity coefficient $\gamma_i = \hat{f}_i/x_i f_i$, where x_i is the liquid-phase mole fraction. The activity is then

$$\hat{a}_i \equiv \frac{\hat{f}_i}{f_i°} = \gamma_i x_i \left(\frac{f_i}{f_i°}\right)$$

Both f_i and $f_i°$ represent fugacity of pure liquid i at temperature T, but at pressures P and $P°$, respectively. Except in the critical region, pressure has little effect on the properties of liquids, and the ratio $f_i/f_i°$ is often taken as unity. When this is not acceptable, this ratio is evaluated by the equation

$$\ln \frac{f_i}{f_i°} = \frac{1}{RT}\int_{P°}^{P} V_i\, dP \simeq \frac{V_i(P - P°)}{RT}$$

When the ratio $f_i/f_i°$ is taken as unity, $\hat{a}_i = \gamma_i x_i$, and Eq. (4-369) becomes

$$\prod_i (\gamma_i x_i)^{\nu_{i,j}} = K_j \qquad \text{all } j \tag{4-373}$$

Here the difficulty is to determine the γ_i's, which depend on the x_i's. This problem has not been solved for the general case. Two courses are open: the first is experiment; the second, assumption of solution ideality. In the latter case, $\gamma_i = 1$, and Eq. (4-373) reduces to

$$\prod_i (x_i)^{\nu_{i,j}} = K_j \qquad \text{all } j \tag{4-374}$$

the "law of mass action." The significant feature of Eqs. (4-372) and (4-374), the simplest expressions for gas- and liquid-phase reaction

equilibrium, is that the temperature-, pressure-, and composition-dependent terms are distinct and separate.

The effect of temperature on the equilibrium constant follows from Eq. (4-41) written for pure species j in its standard state (wherein the pressure P° is fixed):

$$\frac{d(G_j^\circ/RT)}{dT} = \frac{-H_j^\circ}{RT^2}$$

With Eqs. (4-365) and (4-366) this equation easily extends to relate standard property changes of reaction:

$$\frac{d(\Delta G_j^\circ/RT)}{dT} = \frac{-\Delta H_j^\circ}{RT^2} \tag{4-375}$$

In view of Eq. (4-370) this may also be written as

$$\frac{d \ln K_j}{dT} = \frac{\Delta H_j^\circ}{RT^2} \tag{4-376}$$

For an endothermic reaction, ΔH_j° is positive and K_j increases with increasing T; for an exothermic reaction, it is negative and K_j decreases with increasing T.

Because the standard state pressure is constant, Eq. (4-28) may be extended to relate standard properties of reaction, yielding

$$d\Delta H_j^\circ = \Delta C_{P_j}^\circ dT \qquad \text{and} \qquad d\Delta S_j^\circ = \Delta C_{P_j}^\circ \frac{dT}{T}$$

Integration of these equations from reference temperature T_0 (usually 298.15 K) to temperature T gives

$$\Delta H^\circ = \Delta H_0^\circ + R\int_{T_0}^{T} \frac{\Delta C_P^\circ}{R}\, dT \tag{4-377}$$

$$\Delta S^\circ = \Delta S_0^\circ + R\int_{T_0}^{T} \frac{\Delta C_P^\circ}{R} \frac{dT}{T} \tag{4-378}$$

where for simplicity subscript j has been supressed. The definition of G leads directly to $\Delta G^\circ = \Delta H^\circ - T\,\Delta S^\circ$. Combining this equation with Eqs. (4-370), (4-377), and (4-378) yields

$$\ln K = \frac{-\Delta G^\circ}{RT} = \frac{-\Delta H_0^\circ}{RT} - \frac{1}{T}\int_{T_0}^{T} \frac{\Delta C_P^\circ}{R}\, dT + \frac{\Delta S_0^\circ}{R} + \int_{T_0}^{T} \frac{\Delta C_P^\circ}{R} \frac{dT}{T}$$

Substituting $\Delta S_0^\circ = (\Delta G_0^\circ - \Delta H_0^\circ)/T_0$, rearranging, and defining $\tau \equiv T/T_0$ give finally

$$\ln K = \frac{-\Delta G_0^\circ}{RT_0} + \frac{\Delta H_0^\circ}{RT_0}\left(\frac{\tau - 1}{\tau}\right) - \frac{1}{T}\int_{T_0}^{T} \frac{\Delta C_P^\circ}{R}\, dT + \int_{T_0}^{T} \frac{\Delta C_P^\circ}{R} \frac{dT}{T} \tag{4-379}$$

When heat capacity equations have the form of Eq. (4-52), the integrals are evaluated by equations of exactly the form of Eqs. (4-53) and (4-54), but with parameters A, B, C, and D replaced by ΔA, ΔB, ΔC, and ΔD, in accord with Eq. (4-364). Thus for the ideal gas standard state

$$\int_{T_0}^{T} \frac{\Delta C_P^\circ}{R}\, dT = \Delta A\, T_0(\tau - 1) + \frac{\Delta B}{2} T_0^2(\tau^2 - 1) + \frac{\Delta C}{3} T_0^3(\tau^3 - 1) + \frac{\Delta D}{T_0}\left(\frac{\tau - 1}{\tau}\right) \tag{4-380}$$

$$\int_{T_0}^{T} \frac{\Delta C_P^\circ}{R} \frac{dT}{T} = \Delta A \ln \tau + \left[\Delta B\, T_0 + \left(\Delta C\, T_0^2 + \frac{\Delta D}{\tau^2 T_0^2}\right)\left(\frac{\tau + 1}{2}\right)\right](\tau - 1) \tag{4-381}$$

Equations (4-379) through (4-381) together allow an equation to be written for $\ln K$ as a function of T for any reaction for which appropriate data are available.

In the more extensive compilations of data, values of ΔG° and ΔH° for formation reactions are given for a wide range of temperatures, rather than just at the reference temperature $T_0 = 298.15$ K. [See in particular *TRC Thermodynamic Tables—Hydrocarbons* and *TRC Thermodynamic Tables—Non-hydrocarbons*, serial publications of the Thermodynamics Research Center, Texas A & M Univ. System, College Station, Tex.; "The NBS Tables of Chemical Thermodynamic Properties," *J. Phys. Chem. Ref. Data* **11**, supp. 2 (1982).] Where data are lacking, methods of estimation are available; these are reviewed by Poling, Prausnitz, and O'Connell, *The Properties of Gases and Liquids*, 5th ed., chap. 6, McGraw-Hill, New York, 2000. For an estimation procedure based on molecular structure, see Constantinou and Gani, *Fluid Phase Equilib.* **103:** 11–22 (1995). See also Sec. 2.

Example 6: Single-Reaction Equilibrium The hydrogenation of benzene to produce cyclohexane by the reaction

$$C_6H_6 + 3H_2 \rightarrow C_6H_{12}$$

is carried out over a catalyst formulated to repress side reactions. Operating conditions cover a pressure range from 10 to 35 bar and a temperature range from 450 to 670 K. Reaction rate increases with increasing T, but because the reaction is exothermic the equilibrium conversion decreases with increasing T. A comprehensive study of the effect of operating variables on the chemical equilibrium of this reaction has been published by J. Carrero-Mantilla and M. Llano-Restrepo, *Fluid Phase Equilib.* **219:** 181–193 (2004). Presented here are calculations for a single set of operating conditions, namely, $T = 600$ K, $P = 15$ bar, and a molar feed ratio $H_2/C_6H_6 = 3$, the stoichiometric value. For these conditions we determine the fractional conversion of benzene to cyclohexane. Carrero-Mantilla and Llano-Restrepo express $\ln K$ as a function of T by an equation which for 600 K yields the value $K = 0.02874$.

A feed stream containing 3 mol H_2 for each 1 mol C_6H_6 is the *basis* of calculation, and for this single reaction, Eq. (4-361) becomes $n_i = n_{i_0} + \nu_i\varepsilon$, yielding

$$\begin{array}{ll} n_B = 1 - \varepsilon & \text{benzene} \\ n_H = 3 - 3\varepsilon & \text{hydrogen} \\ n_C = \varepsilon & \text{cyclohexane} \\ \hline \sum_i n_i = 4 - 3\varepsilon & \end{array}$$

Each mole fraction is therefore given by $y_i = n_i/(4 - 3\varepsilon)$.

Assume first that the equilibrium mixture is an ideal gas, and apply Eq. (4-372), written for a single reaction, with subscript j omitted and $\nu = -3$:

$$\prod_i y_i^{\nu_i}\left(\frac{P}{P^\circ}\right)^{\nu} = \frac{\dfrac{\varepsilon}{4 - 3\varepsilon}}{\left(\dfrac{1 - \varepsilon}{4 - 3\varepsilon}\right)\left(\dfrac{3 - 3\varepsilon}{4 - 3\varepsilon}\right)^3}\left(\frac{15}{1}\right)^{-3} = K = 0.02874$$

whence $$\frac{\varepsilon}{1 - \varepsilon}\left(\frac{4 - 3\varepsilon}{3 - 3\varepsilon}\right)^3 (15)^{-3} = 0.02874 \qquad \text{and} \qquad \varepsilon = 0.815$$

Thus, the assumption of ideal gases leads to a calculated conversion of 81.5 percent.

An alternative assumption is that the equilibrium mixture is an ideal solution. This requires application of Eq. (4-371). However, in the case of an ideal solution Eq. (4-218) indicates that $\hat{\phi}_i^{id} = \phi_i$, in which case Eq. (4-371) for a single reaction becomes

$$\prod_i (y_i\phi_i)^{\nu_i}\left(\frac{P}{P^\circ}\right)^{\nu} = K$$

For purposes of illustration we evaluate the pure-species fugacity coefficients by Eq. (4-206), written here as

$$\phi_i = \exp(B_i^0 + \omega B_i^1)\frac{P_{r_i}}{T_{r_i}}$$

The following table shows values for the various quantities in this equation. Note that T_c and P_c for hydrogen are *effective* values as calculated by Eqs. (4-124) and (4-125) and used with $\omega = 0$.

	T_c	T_r	P_c	P_r	ω	B^0	B^1	ϕ
C_6H_6	562.2	1.067	48.98	0.306	0.21	−0.2972	0.008	0.919
H_2	42.8	14.009	19.78	0.758	0.00	0.0768	0.139	1.004
C_6H_{12}	553.6	1.084	40.73	0.368	0.21	−0.2880	0.016	0.908

The equilibrium equation now becomes:

$$\prod_i (y_i\phi_i)^{\nu_i}\left(\frac{P}{P^\circ}\right)^{\nu} = \frac{\dfrac{\varepsilon}{4-3\varepsilon}\,0.919}{\left(\dfrac{1-\varepsilon}{4-3\varepsilon}0.908\right)\left(\dfrac{3-3\varepsilon}{4-3\varepsilon}1.004\right)^3}\left(\frac{15}{1}\right)^{-3} = K = 0.02874$$

Solution yields $\varepsilon = 0.816$

This result is hardly different from that based on the ideal gas assumption. The fugacity coefficients in the equilibrium equation clearly cancel one another. This is not uncommon in reaction equilibrium calculations, as there are always products and reactions, making the ideal gas assumption far more useful than might be expected.

Carrero-Mantilla and Llano-Restrep present results for a wide range of conditions, both for the ideal gas assumption and for calculations wherein $\hat{\phi}_i$ values are determined from the Soave-Redlich-Kwong equation of state. In no case are these calculated conversions significantly divergent.

Complex Chemical Reaction Equilibria When the composition of an equilibrium mixture is determined by a number of simultaneous reactions, calculations based on equilibrium constants become complex and tedious. A more direct procedure (and one suitable for general computer solution) is based on minimization of the total Gibbs energy G^t in accord with Eq. (4-293). The treatment here is limited to gas-phase reactions for which the problem is to find the equilibrium composition for given T and P and for a given initial feed.

1. Formulate the constraining material-balance equations, based on conservation of the total number of atoms of each *element* in a system comprised of w elements. Let subscript k identify a particular atom, and define A_k as the total number of atomic masses of the kth element in the feed. Further, let a_{ik} be the number of atoms of the kth element present in each molecule of chemical species i. The material balance for element k is then

$$\sum_i n_i a_{ik} = A_k \qquad k = 1, 2, \ldots, w \tag{4-382}$$

or

$$\sum_i n_i a_{ik} - A_k = 0 \qquad k = 1, 2, \ldots, w$$

2. Multiply each element balance by λ_k, a Lagrange multiplier:

$$\lambda_k\left(\sum_i n_i a_{ik} - A_k\right) = 0 \qquad k = 1, 2, \ldots, w$$

Summed over k, these equations give

$$\sum_k \lambda_k\left(\sum_i n_i a_{ik} - A_k\right) = 0$$

3. Form a function F by addition of this sum to G^t:

$$F = G^t + \sum_k \lambda_k\left(\sum_i n_i a_{ik} - A_k\right)$$

Function F is identical with G^t, because the summation term is zero. However, the partial derivatives of F and G^t with respect to n_i are different, because function F incorporates the constraints of the material balances.

4. The minimum value of both F and G^t is found when the partial derivatives of F with respect to n_i are set equal to zero:

$$\left(\frac{\partial F}{\partial n_i}\right)_{T,P,n_j} = \left(\frac{\partial G^t}{\partial n_i}\right)_{T,P,n_j} + \sum_k \lambda_k a_{ik} = 0$$

The first term on the right is the definition of the chemical potential; therefore,

$$\mu_i + \sum_k \lambda_k a_{ik} = 0 \qquad i = 1, 2, \ldots, N \tag{4-383}$$

However, the chemical potential is given by Eq. (4-368); for gas-phase reactions and standard states as the pure ideal gases at P^o, this equation becomes

$$\mu_i = G_i^\circ + RT \ln \frac{\hat{f}_i}{P^\circ}$$

If G_i° is arbitrarily set equal to zero for all *elements* in their standard states, then for compounds $G_i^\circ = \Delta G_{f_i}^\circ$, the standard Gibbs energy change of formation of species i. In addition, the fugacity is eliminated—in favor of the fugacity coefficient by Eq. (4-204), $\hat{f}_i = y_i\hat{\phi}_i P$. With these substitutions, the equation for μ_i becomes

$$\mu_i = \Delta G_{f_i}^\circ + RT \ln \frac{y_i\hat{\phi}_i P}{P^\circ}$$

Combination with Eq. (4-383) gives

$$\Delta G_{f_i}^\circ + RT \ln \frac{y_i\hat{\phi}_i P}{P^\circ} + \sum_k \lambda_k a_{ik} = 0 \qquad i = 1, 2, \ldots, N \tag{4-384}$$

If species i is an element, $\Delta G_{f_i}^\circ$ is zero. There are N equilibrium equations [Eqs. (4-384)], one for each chemical species, and there are w material balance equations [Eqs. (4-382)], one for each element—a total of $N + w$ equations. The unknowns in these equations are the n_i's (note that $y_i = n_i/\Sigma_i n_i$), of which there are N, and the λ_k's, of which there are w—a total of $N + w$ unknowns. Thus the number of equations is sufficient for the determination of all unknowns.

Equation (4-384) is derived on the presumption that the set $\{\hat{\phi}_i\}$ is known. If the phase is an ideal gas, then each $\hat{\phi}_i$ is unity. If the phase is an ideal solution, each $\hat{\phi}_i$ becomes ϕ_i and can at least be estimated. For real gases, each $\hat{\phi}_i$ is a function of the set $\{y_i\}$, the quantities being calculated. Thus an iterative procedure is indicated, initiated with each $\hat{\phi}_i$ set equal to unity. Solution of the equations then provides a preliminary set $\{y_i\}$. For low pressures or high temperatures this result is usually adequate. Where it is not satisfactory, an equation of state with the preliminary set $\{y_i\}$ gives a new and more nearly correct set $\{\hat{\phi}_i\}$ for use in Eq. (4-384). Then a new set $\{y_i\}$ is determined. The process is repeated to convergence. All calculations are well suited to computer solution.

In this procedure, the question of what chemical reactions are involved never enters directly into any of the equations. However, the choice of a set of species is entirely equivalent to the choice of a set of independent reactions among the species. In any event, a set of species or an equivalent set of independent reactions must always be assumed, and different assumptions produce different results.

A detailed example of a complex gas-phase equilibrium calculation is given by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 5th ed., Example 15.13, pp. 602–604; 6th ed., Example 13.14, pp. 511–513; 7th ed., Example 13.14, pp. 527–528, McGraw-Hill, New York (1996, 2001, 2005)]. General application of the method to multicomponent, multiphase systems is treated by Iglesias-Silva et al. [*Fluid Phase Equilib.* **210:** 229–245 (2003)] and by Sotyan, Ghajar, and Gasem [*Ind. Eng. Chem. Res.* **42:** 3786–3801 (2003)].

THERMODYNAMIC ANALYSIS OF PROCESSES

Real irreversible processes can be subjected to thermodynamic analysis. The goal is to calculate the efficiency of energy use or production and to show how wasted energy is apportioned among the steps of a process. The treatment here is limited to steady-state steady-flow processes, because of their predominance in chemical technology.

CALCULATION OF IDEAL WORK

In any steady-state steady-flow process *requiring* work, a minimum amount must be expended to bring about a specific change of state in the flowing fluid. In a process *producing* work, a maximum amount is

attainable for a specific change of state in the flowing fluid. In either case, the limiting value obtains when the specific change of state is accomplished *completely reversibly*. The implications of this requirement are that

1. The process is internally reversible within the control volume.
2. Heat transfer external to the control volume is reversible.

The second item means that heat exchange between system and surroundings must occur at the temperature of the surroundings, presumed to constitute a heat reservoir at a constant and uniform temperature T_σ. This may require Carnot engines or heat pumps internal to the system that provide for the reversible transfer of heat from the temperatures of the flowing fluid to that of the surroundings. Because Carnot engines and heat pumps are cyclic, they undergo no net change of state.

These conditions are implicit in the entropy balance of Eq. (4-156) when $\dot{S}_G = 0$. If in addition there is but a single surroundings temperature T_σ, this equation becomes

$$\Delta(S\dot{m})_{fs} - \frac{\dot{Q}}{T_\sigma} = 0 \tag{4-385}$$

The energy balance for a steady-state steady-flow process as given by Eq. (4-150) is

$$\Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W}_s \tag{4-150}$$

Combining this equation with Eq. (4-385) to eliminate $\dot{Q}$ yields

$$\Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = T_\sigma\,\Delta(S\dot{m})_{fs} + \dot{W}_s(\text{rev})$$

where $\dot{W}_s(\text{rev})$ indicates that the shaft work is for a completely reversible process. This work is called the *ideal work* $\dot{W}_{ideal}$. Thus

$$\dot{W}_{ideal} = \Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} - T_\sigma\,\Delta(S\dot{m})_{fs} \tag{4-386}$$

In most applications to chemical processes, the kinetic and potential energy terms are negligible compared with the others; in this event Eq. (4-386) is written as

$$\dot{W}_{ideal} = \Delta(H\dot{m})_{fs} - T_\sigma\,\Delta(S\dot{m})_{fs} \tag{4-387}$$

For the special case of a single stream flowing through the system, Eq. (4-387) becomes

$$\dot{W}_{ideal} = \dot{m}(\Delta H - T_\sigma\,\Delta S) \tag{4-388}$$

Division by $\dot{m}$ puts this equation on a unit-mass basis:

$$W_{ideal} = \Delta H - T_\sigma\,\Delta S \tag{4-389}$$

A completely reversible process is hypothetical, devised solely to find the ideal work associated with a given change of state. Its only connection with an actual process is that it brings about the same change of state as the actual process, allowing comparison of the actual work of a process with the work of the hypothetical reversible process.

Equations (4-386) through (4-389) give the work of a completely reversible process associated with given property changes in the flowing streams. When the same property changes occur in an actual process, the actual work $\dot{W}_s$ (or W_s) is given by an energy balance, and comparison can be made of the actual work with the ideal work. When $\dot{W}_{ideal}$ (or W_{ideal}) is positive, it is the *minimum work required* to bring about a given change in the properties of the flowing streams, and it is smaller than $\dot{W}_s$. In this case a thermodynamic efficiency η_t is defined as the ratio of the ideal work to the actual work:

$$\eta_t(\text{work required}) = \frac{\dot{W}_{ideal}}{\dot{W}_s} \tag{4-390}$$

When $\dot{W}_{ideal}$ (or W_{ideal}) is negative, $|\dot{W}_{ideal}|$ is the *maximum work obtainable* from a given change in the properties of the flowing streams, and it is larger than $|\dot{W}_s|$. In this case, the thermodynamic efficiency is defined as the ratio of the actual work to the ideal work:

$$\eta_t(\text{work produced}) = \frac{\dot{W}_s}{\dot{W}_{ideal}} \tag{4-391}$$

LOST WORK

Work that is wasted as the result of irreversibilities in a process is called *lost work* $\dot{W}_{lost}$, and it is defined as the difference between the actual work of a process and the ideal work for the process. Thus by definition,

$$W_{lost} \equiv W_s - W_{ideal} \tag{4-392}$$

The rate form is

$$\dot{W}_{lost} \equiv \dot{W}_s - \dot{W}_{ideal} \tag{4-393}$$

The actual work rate comes from Eq. (4-150):

$$\dot{W}_s = \Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} - \dot{Q}$$

Subtracting the ideal work rate as given by Eq. (4-386) yields

$$\dot{W}_{lost} = T_\sigma\,\Delta(S\dot{m})_{fs} - \dot{Q} \tag{4-394}$$

For the special case of a single stream flowing through the control volume,

$$\dot{W}_{lost} = \dot{m}T_\sigma\,\Delta S - \dot{Q} \tag{4-395}$$

Division of this equation by $\dot{m}$ gives

$$W_{lost} = T_\sigma\,\Delta S - Q \tag{4-396}$$

where the basis is now a unit amount of fluid flowing through the control volume.

The total rate of entropy generation (in both system and surroundings) as a result of a process is

$$\dot{S}_G = \Delta(S\dot{m})_{fs} - \frac{\dot{Q}}{T_\sigma} \tag{4-397}$$

Division by $\dot{m}$ provides an equation based on a unit amount of fluid flowing through the control volume:

$$S_G = \Delta S - \frac{Q}{T_\sigma} \tag{4-398}$$

Equations (4-397) and (4-398) are special cases of Eqs. (4-156) and (4-157).

Multiplication of Eq. (4-397) by T_σ gives

$$T_\sigma\dot{S}_G = T_\sigma\,\Delta(S\dot{m})_{fs} - \dot{Q}$$

Because the right sides of this equation and of Eq. (4-394) are identical, it follows that

$$\dot{W}_{lost} = T_\sigma\dot{S}_G \tag{4-399}$$

For flow on the basis of a unit amount of fluid, this becomes

$$W_{lost} = T_\sigma S_G \tag{4-400}$$

Because the second law of thermodynamics requires

$$\dot{S}_G \ge 0 \qquad \text{and} \qquad S_G \ge 0$$

therefore

$$\dot{W}_{lost} \ge 0 \qquad \text{and} \qquad W_{lost} \ge 0$$

When a process is completely reversible, the equality holds and the lost work is zero. For irreversible processes the inequality holds, and the lost work, i.e., the energy that becomes unavailable for work, is positive. The engineering significance of this result is clear: The greater the irreversibility of a process, the greater the rate of entropy generation and the greater the amount of energy that becomes unavailable for work. Thus every irreversibility carries with it a price.

ANALYSIS OF STEADY-STATE STEADY-FLOW PROCESSES

Many processes consist of a number of steps, and lost-work calculations are then made for each step separately. Writing Eq. (4-399) for each step of the process and summing give

$$\sum \dot{W}_{lost} = T_\sigma \sum \dot{S}_G$$

Dividing Eq. (4-399) by this result yields

$$\frac{\dot{W}_{\text{lost}}}{\sum \dot{W}_{\text{lost}}} = \frac{\dot{S}_G}{\sum \dot{S}_G}$$

Thus an analysis of the lost work, made by calculation of the fraction that each individual lost-work term represents of the total lost work, is the same as an analysis of the rate of entropy generation, made by expressing each individual entropy generation term as a fraction of the sum of all entropy generation terms.

An alternative to the lost-work or entropy generation analysis is a work analysis. This is based on Eq. (4-393), written as

$$\sum \dot{W}_{\text{lost}} = \dot{W}_s - \dot{W}_{\text{ideal}} \tag{4-401}$$

For a work-requiring process, all these work quantities are positive and $\dot{W}_s > \dot{W}_{\text{ideal}}$. The preceding equation is then expressed as

$$\dot{W}_s = \dot{W}_{\text{ideal}} + \sum \dot{W}_{\text{lost}} \tag{4-402}$$

A work analysis then gives each of the individual work terms in the summation on the right as a fraction of $\dot{W}_s$.

For a work-producing process, $\dot{W}_s$ and $\dot{W}_{\text{ideal}}$ are negative, and $|\dot{W}_{\text{ideal}}| > |\dot{W}_s|$. Equation (4-401) in this case is best written as

$$|\dot{W}_{\text{ideal}}| = |\dot{W}_s| + \sum \dot{W}_{\text{lost}} \tag{4-403}$$

A work analysis here expresses each of the individual work terms on the right as a fraction of $|\dot{W}_{\text{ideal}}|$. A work analysis cannot be carried out in the case where a process is so inefficient that $\dot{W}_{\text{ideal}}$ is negative, indicating that the process should produce work; but $\dot{W}_s$ is positive, indicating that the process in fact requires work. A lost-work or entropy generation analysis is always possible.

Example 7: Lost-Work Analysis A work analysis follows for a simple Linde system for the separation of air into gaseous oxygen and nitrogen, as depicted in Fig. 4-10. Table 4-8 lists a set of operating conditions for the numbered points of the diagram. Heat leaks into the column of 147 J/mol of entering air and into the exchanger of 70 J/mol of entering air have been assumed. Take $T_\sigma = 300$ K.

The basis for analysis is 1 mol of entering air, assumed to contain 79 mol % N_2 and 21 mol % O_2. By a material balance on the nitrogen, $0.79 = 0.9148\,x$, whence

$$x = 0.8636 \text{ mol of nitrogen product}$$
$$1 - x = 0.1364 \text{ mol of oxygen product}$$

Calculation of ideal work: If changes in kinetic and potential energies are neglected, Eq. (4-387) is applicable. From the tabulated data,

$$\Delta(H\dot{m})_{\text{fs}} = (13{,}460)(0.1364) + (12{,}074)(0.8636) - (12{,}407)(1) = -144 \text{ J}$$
$$\Delta(S\dot{m})_{\text{fs}} = (118.48)(0.1364) + (114.34)(0.8636) - (117.35)(1) = -2.4453 \text{ J/K}$$

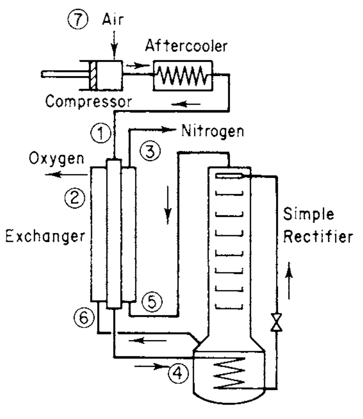

FIG. 4-10 Diagram of simple Linde system for air separation.

TABLE 4-8 States and Values of Properties for the Process of Fig. 4-10*

Point	P, bar	T, K	Composition	State	H, J/mol	S, J/(mol·K)
1	55.22	300	Air	Superheated	12,046	82.98
2	1.01	295	Pure O_2	Superheated	13,460	118.48
3	1.01	295	91.48% N_2	Superheated	12,074	114.34
4	55.22	147.2	Air	Superheated	5,850	52.08
5	1.01	79.4	91.48% N_2	Saturated vapor	5,773	75.82
6	1.01	90	Pure O_2	Saturated vapor	7,485	83.69
7	1.01	300	Air	Superheated	12,407	117.35

*Properties on the basis of Miller and Sullivan, U.S. Bur. Mines Tech. Pap. 424 (1928).

Thus, by Eq. (4-387),

$$\dot{W}_{\text{ideal}} = -144 - (300)(-2.4453) = 589.6 \text{ J}$$

Calculation of actual work of compression: For simplicity, the work of compression is calculated by the equation for an ideal gas in a three-stage reciprocating machine with complete intercooling and with isentropic compression in each stage. The work so calculated is assumed to represent 80 percent of the actual work. The following equation may be found in any number of textbooks on thermodynamics:

$$\dot{W}_s = \frac{n\gamma RT_1}{0.8(\gamma - 1)}\left[\left(\frac{P_2}{P_1}\right)^{(\gamma-1)/n\gamma} - 1\right]$$

where n = number of stages, here taken as 3
γ = ratio of heat capacities, here taken as 1.4
T_1 = initial absolute temperature, equal to 300 K
P_2/P_1 = overall pressure ratio, equal to 54.5
R = universal gas constant, equal to 8.314 J/(mol·K)

The efficiency factor of 0.8 is already included in the equation. Substitution of the remaining values gives

$$\dot{W}_s = \frac{(3)(1.4)(8.314)(300)}{(0.8)(0.4)}\left[(54.5)^{0.4/(3)(1.4)} - 1\right] = 15{,}171 \text{ J}$$

The heat transferred to the surroundings during compression as a result of intercooling and aftercooling to 300 K is found from the first law:

$$\dot{Q} = \dot{m}(\Delta H) - \dot{W}_s = (12{,}046 - 12{,}407) - 15{,}171 = -15{,}532 \text{ J}$$

Calculation of lost work: Equation (4-394) may be applied to each of the major units of the process. For the compressor/cooler,

$$\dot{W}_{\text{lost}} = (300)[(82.98)(1) - (117.35)(1)] - (-15{,}532) = 5221.0 \text{ J}$$

For the exchanger,

$$\dot{W}_{\text{lost}} = (300)[(118.48)(0.1364) + (114.34)(0.8636) + (52.08)(1) - (75.82)(0.8636) - (83.69)(0.1364) - (82.98)(1)] - 70 = 2063.4 \text{ J}$$

Finally, for the rectifier,

$$\dot{W}_{\text{lost}} = (300)[(75.82)(0.8636) + (83.69)(0.1364) - (52.08)(1)] - 147 = 7297.0 \text{ J}$$

Work analysis: Because the process requires work, Eq. (4-402) is appropriate for a work analysis. The various terms of this equation appear as entries in the following table and are on the basis of 1 mol of entering air.

			% of $\dot{W}_s$
$\dot{W}_{\text{ideal}}$		589.6 J	3.9
$\dot{W}_{\text{lost}}$:	Compressor/cooler	5,221.0 J	34.4
$\dot{W}_{\text{lost}}$:	Exchanger	2,063.4 J	13.6
$\dot{W}_{\text{lost}}$:	Rectifier	7,297.0 J	48.1
$\dot{W}_s$		15,171.0 J	100.0

The thermodynamic efficiency of this process as given by Eq. (4-390) is only 3.9 percent. Significant inefficiencies reside with each of the primary units of the process.

MODES OF HEAT TRANSFER

Heat is energy transferred due to a difference in temperature. There are three modes of heat transfer: conduction, convection, and radiation. All three may act at the same time. Conduction is the transfer of energy between adjacent particles of matter. It is a local phenomenon and can only occur through matter. Radiation is the transfer of energy from a point of higher temperature to a point of lower energy by electromagnetic radiation. Radiation can act at a distance through transparent media and vacuum. Convection is the transfer of energy by conduction and radiation in moving, fluid media. The motion of the fluid is an essential part of convective heat transfer.

HEAT TRANSFER BY CONDUCTION

FOURIER'S LAW

The heat flux due to conduction in the *x* direction is given by Fourier's law

$$\dot{Q} = -kA\frac{dT}{dx} \tag{5-1}$$

where $\dot{Q}$ is the rate of heat transfer (W), k is the thermal conductivity [W/(m·K)], A is the area perpendicular to the x direction, and T is temperature (K). For the homogeneous, one-dimensional plane shown in Fig. 5-1*a*, with constant k, the integrated form of (5-1) is

$$\dot{Q} = kA\frac{T_1 - T_2}{\Delta x} \tag{5-2}$$

where Δx is the thickness of the plane. Using the thermal circuit shown in Fig. 5-1*b*, Eq. (5-2) can be written in the form

$$\dot{Q} = \frac{T_1 - T_2}{\Delta x/kA} = \frac{T_1 - T_2}{R} \tag{5-3}$$

where R is the thermal resistance (K/W).

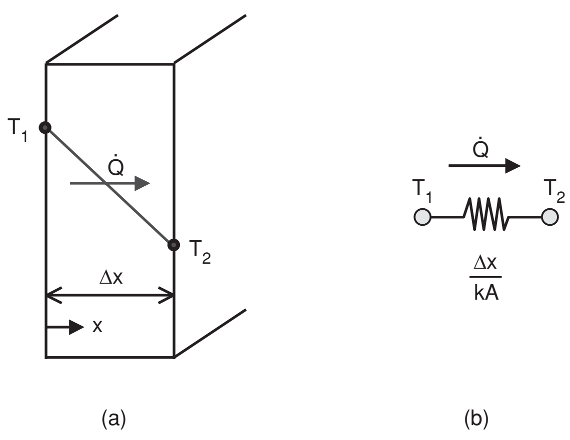

FIG. 5-1 Steady, one-dimensional conduction in a homogeneous planar wall with constant k. The thermal circuit is shown in (*b*) with thermal resistance $\Delta x/(kA)$.

THERMAL CONDUCTIVITY

The thermal conductivity k is a transport property whose value for a variety of gases, liquids, and solids is tabulated in Sec. 2. Section 2 also provides methods for predicting and correlating vapor and liquid thermal conductivities. The thermal conductivity is a function of temperature, but the use of constant or averaged values is frequently sufficient. Room temperature values for air, water, concrete, and copper are 0.026, 0.61, 1.4, and 400 W/(m · K). Methods for estimating contact resistances and the thermal conductivities of composites and insulation are summarized by Gebhart, *Heat Conduction and Mass Diffusion*, McGraw-Hill, 1993, p. 399.

STEADY-STATE CONDUCTION

One-Dimensional Conduction In the absence of energy source terms, $\dot{Q}$ is constant with distance, as shown in Fig. 5-1*a.* For steady conduction, the integrated form of (5-1) for a planar system with constant k and A is Eq. (5-2) or (5-3). For the general case of variables k (k is a function of temperature) and A (cylindrical and spherical systems with radial coordinate r, as sketched in Fig. 5-2), the average heat-transfer area and thermal conductivity are defined such that

$$\dot{Q} = \overline{kA}\,\frac{T_1 - T_2}{\Delta x} = \frac{T_1 - T_2}{R} \tag{5-4}$$

For a thermal conductivity that depends linearly on T,

$$k = k_0(1 + \gamma T) \tag{5-5}$$

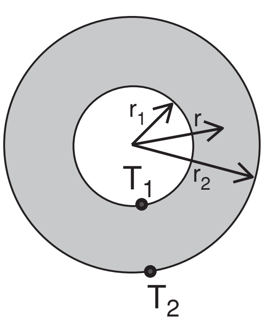

FIG. 5-2 The hollow sphere or cylinder.

Nomenclature and Units—Heat Transfer by Conduction, by Convection, and with Phase Change

Symbol	Definition	SI units
A	Area for heat transfer	m^2
A_c	Cross-sectional area	m^2
A_f	Area for heat transfer for finned portion of tube	m^2
A_i	Inside area of tube	
A_o	External area of bare, unfinned tube	m^2
A_{of}	External area of tube before tubes are attached = A_o	m^2
A_T	Total external area of finned tube	m^2
A_{uf}	Area for heat transfer for unfinned portion of finned tube	m^2
A_1	First Fourier coefficient	
a_x	Cross-sectional area of fin	m^2
b	Geometry: $b = 1$, plane; $b = 2$, cylinder; $b = 3$, sphere	
b_f	Height of fin	m
B_1	First Fourier coefficient	
Bi	Biot number, hR/k	
c	Specific heat	J/(kg·K)
c_p	Specific heat, constant pressure	J/(kg·K)
D	Diameter	m
D_i	Inner diameter	m
D_o	Outer diameter	m
f	Fanning friction factor	
Fo	Dimensionless time or Fourier number, $\alpha t/R^2$	
g_c	Conversion factor	1.0 kg·m/(N·s^2)
g	Acceleration of gravity, 9.81 m^2/s	m^2/s
G	Mass velocity, $\dot{m}/A_c$; G_v for vapor mass velocity	kg/(m^2·s)
G_{max}	Mass velocity through minimum free area between rows of tubes normal to the fluid stream	kg/(m^2·s)
Gz	Graetz number = Re Pr	
h	Heat-transfer coefficient	W/(m^2·K)
$\overline{h}$	Average heat-transfer coefficient	W/(m^2·K)
h_f	Heat-transfer coefficient for finned-tube exchangers based on total external surface	W/(m^2·K)
h_f	Outside heat-transfer coefficient calculated for a bare tube for use with Eq. (5-73)	W/(m^2·K)
h_{fi}	Effective outside heat-transfer coefficient based on inside area of a finned tube	W/(m^2·K)
h_i	Heat-transfer coefficient at inside tube surface	W/(m^2·K)
h_o	Heat-transfer coefficient at outside tube surface	W/(m^2·K)
h_{am}	Heat-transfer coefficient for use with ΔT_{am}, see Eq. (5-33)	W/(m^2·K)
h_{lm}	Heat-transfer coefficient for use with ΔT_{lm}; see Eq. (5-32)	W/(m^2·K)
k	Thermal conductivity	W/(m·K)
$\overline{k}$	Average thermal conductivity	W/(m·K)
L	Length of cylinder or length of flat plate in direction of flow or downstream distance. Length of heat-transfer surface	m
m	Fin parameter defined by Eq. (5-75).	
$\dot{m}$	Mass flow rate	kg/s
Nu_D	Nusselt number based on diameter D, hD/k	
$\overline{Nu}_D$	Average Nusselt number based on diameter D, $\overline{h}D/k$	
Nu_{lm}	Nusselt number based on h_{lm}	
n'	Flow behavior index for nonnewtonian fluids	
p	Perimeter	m
p_f	Fin perimeter	m
p'	Center-to-center spacing of tubes in a bundle	m
P	Absolute pressure; P_c for critical pressure	kPa
Pr	Prandtl number, ν/α	
q	Rate of heat transfer	W
Q	Amount of heat transfer	J
$\dot{Q}$	Rate of heat transfer	W
Q/Q_i	Heat loss fraction, $Q/[\rho c V(T_i - T_\infty)]$	
r	Distance from center in plate, cylinder, or sphere	m
R	Thermal resistance or radius	K/W or m
Ra_x	Rayleigh number, $\beta\,\Delta T\,gx^3/\nu\alpha$	
Re_D	Reynolds number, GD/μ	
S	Volumetric source term	W/m^3
S	Cross-sectional area	m^2
S_1	Fourier spatial function	
t	Time	s
t_{sv}	Saturated-vapor temperature	K
t_s	Surface temperature	K
T	Temperature	K or °C
T_b	Bulk or mean temperature at a given cross section	K
$\overline{T}_b$	Bulk mean temperature, $(T_{b,in} + T_{b,out})/2$	K
T_C	Temperature of cold surface in enclosure	K
T_f	Film temperature, $(T_s + T_e)/2$	K
T_H	Temperature of hot surface in enclosure	K
T_i	Initial temperature	K
T_e	Temperature of free stream	K
T_s	Temperature of surface	K
T_∞	Temperature of fluid in contact with a solid surface	K
U	Overall heat-transfer coefficient	W/(m^2·K)
V	Volume	m^3
V_F	Velocity of fluid approaching a bank of finned tubes	m/s
V_∞	Velocity upstream of tube bank	m/s
W_F	Total rate of vapor condensation on one tube	kg/s
x	Cartesian coordinate direction, characteristic dimension of a surface, or distance from entrance	m
x	Vapor quality, x_i for inlet and x_o for outlet	
z_p	Distance (perimeter) traveled by fluid across fin	m

Greek Symbols

Symbol	Definition	SI units
α	Thermal diffusivity, $k/(\rho c)$	m^2/s
β	Volumetric coefficient of expansion	K^{-1}
β'	Contact angle between a bubble and a surface	°
Γ	Mass flow rate per unit length perpendicular to flow	kg/(m·s)
ΔP	Pressure drop	Pa
Δt	Temperature difference	K
ΔT	Temperature difference	K
ΔT_{am}	Arithmetic mean temperature difference, see Eq. (5-32)	K
ΔT_{lm}	Logarithmic mean temperature difference, see Eq. (5-33)	K
Δx	Thickness of plane wall for conduction	m
δ_1	First dimensionless eigenvalue	
$\delta_{1,0}$	First dimensionless eigenvalue as Bi approaches 0	
$\delta_{1,\infty}$	First dimensionless eigenvalue as Bi approaches ∞	
δ_S	Correction factor, ratio of nonnewtonian to newtonian shear rates	
ε	Emissivity of a surface	
ζ	Dimensionless distance, r/R	
θ/θ_i	Dimensionless temperature, $(T - T_\infty)/(T_i - T_\infty)$	
λ	Latent heat (enthalpy) of vaporization (condensation)	J/kg
μ	Viscosity; μ_l, μ_L viscosity of liquid; μ_G, μ_g, μ_v viscosity of gas or vapor	kg/(m·s)
ν	Kinematic viscosity, μ/ρ	m^2/s
ρ	Density; ρ_L, ρ_l for density of liquid; ρ_G, ρ_v for density of vapor	kg/m^3
σ	Stefan-Boltzmann constant, 5.67×10^{-8}	W/(m^2·K^4)
σ	Surface tension between and liquid and its vapor	N/m
τ	Time constant, time scale	s
Ω	Efficiency of fin	

and the average heat thermal conductivity is

$$\bar{k} = k_0(1 + \gamma \bar{T}) \tag{5-6}$$

where $\bar{T} = 0.5(T_1 + T_2)$.

For cylinders and spheres, A is a function of radial position (see Fig. 5-2): $2\pi rL$ and $4\pi r^2$, where L is the length of the cylinder. For constant k, Eq. (5-4) becomes

$$\dot{Q} = \frac{T_1 - T_2}{[\ln(r_2/r_1)]/(2\pi kL)} \qquad \text{cylinder} \tag{5-7}$$

and

$$\dot{Q} = \frac{T_1 - T_2}{(r_2 - r_1)/(4\pi k r_1 r_2)} \qquad \text{sphere} \tag{5-8}$$

Conduction with Resistances in Series A steady-state temperature profile in a planar composite wall, with three constant thermal conductivities and no source terms, is shown in Fig. 5-3*a*. The corresponding thermal circuit is given in Fig. 5-3*b*. The rate of heat transfer through each of the layers is the same. The total resistance is the sum of the individual resistances shown in Fig. 5-3*b*:

$$Q = \frac{T_1 - T_2}{\dfrac{\Delta X_A}{k_A A} + \dfrac{\Delta X_B}{k_B A} + \dfrac{\Delta X_C}{k_C A}} = \frac{T_1 - T_2}{R_A + R_B + R_C} \tag{5-9}$$

Additional resistances in the series may occur at the surfaces of the solid if they are in contact with a fluid. The rate of convective heat transfer, between a surface of area A and a fluid, is represented by Newton's law of cooling as

$$\dot{Q} = hA(T_{\text{surface}} - T_{\text{fluid}}) = \frac{T_{\text{surface}} - T_{\text{fluid}}}{1/(hA)} \tag{5-10}$$

where $1/(hA)$ is the resistance due to convection (K/W) and the heat-transfer coefficient is h[W/(m^2·K)]. For the cylindrical geometry shown in Fig. 5-2, with convection to inner and outer fluids at temperatures T_i and T_o, with heat-transfer coefficients h_i and h_o, the steady-state rate of heat transfer is

$$\dot{Q} = \frac{T_i - T_o}{\dfrac{1}{2\pi r_1 L h_i} + \dfrac{\ln(r_2/r_1)}{2\pi kL} + \dfrac{1}{2\pi r_2 L h_o}} = \frac{T_i - T_o}{R_i + R_1 + R_o} \tag{5-11}$$

where resistances R_i and R_o are the convective resistances at the inner and outer surfaces. The total resistance is again the sum of the resistances in series.

Example 1: Conduction with Resistances in Series and Parallel Figure 5-4 shows the thermal circuit for a furnace wall. The outside surface has a known temperature $T_2 = 625$ K. The temperature of the surroundings

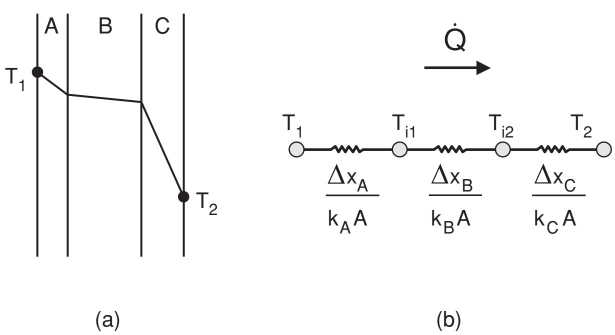

FIG. 5-3 Steady-state temperature profile in a composite wall with constant thermal conductivities k_A, k_B, and k_C and no energy sources in the wall. The thermal circuit is shown in (*b*). The total resistance is the sum of the three resistances shown.

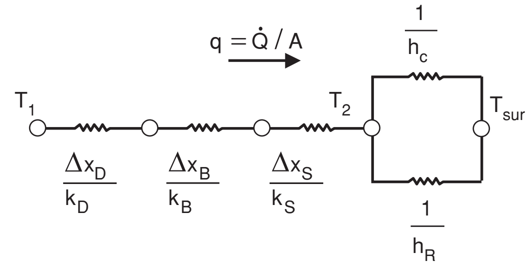

FIG. 5-4 Thermal circuit for Example 1. Steady-state conduction in a furnace wall with heat losses from the outside surface by convection (h_C) and radiation (h_R) to the surroundings at temperature T_{sur}. The thermal conductivities k_D, k_B, and k_S are constant, and there are no sources in the wall. The heat flux q has units of W/m^2.

T_{sur} is 290 K. We want to estimate the temperature of the inside wall T_1. The wall consists of three layers: deposit [$k_D = 1.6$ W/(m·K), $\Delta x_D = 0.080$ *m*], brick [$k_B = 1.7$ W/(m·K), $\Delta x_B = 0.15$ m], and steel [$k_S = 45$ W/(m·K), $\Delta x_S = 0.00254$ m]. The outside surface loses heat by two parallel mechanisms—convection and radiation. The convective heat-transfer coefficient $h_C = 5.0$ W/(m^2·K). The radiative heat-transfer coefficient $h_R = 16.3$ W/(m^2·K). The latter is calculated from

$$h_R = \varepsilon_2 \sigma (T_2^2 + T_{\text{sur}}^2)(T_2 + T_{\text{sur}}) \tag{5-12}$$

where the emissivity of surface 2 is $\varepsilon_2 = 0.76$ and the Stefan-Boltzmann constant $\sigma = 5.67 \times 10^{-8}$ W/(m^2·K^4).

Referring to Fig. 5-4, the steady-state heat flux q (W/m^2) through the wall is

$$q = \frac{\dot{Q}}{A} = \frac{T_1 - T_2}{\dfrac{\Delta X_D}{k_D} + \dfrac{\Delta X_B}{k_B} + \dfrac{\Delta X_S}{k_S}} = (h_C + h_R)(T_2 - T_{\text{sur}})$$

Solving for T_1 gives

$$T_1 = T_2 + \left(\frac{\Delta x_D}{k_D} + \frac{\Delta x_B}{k_B} + \frac{\Delta x_S}{k_S}\right)(h_C + h_R)(T_2 - T_{\text{sur}})$$

and

$$T_1 = 625 + \left(\frac{0.080}{1.6} + \frac{0.15}{1.7} + \frac{0.00254}{45}\right)(5.0 + 16.3)(625 - 290) = 1610 \text{ K}$$

Conduction with Heat Source Application of the law of conservation of energy to a one-dimensional solid, with the heat flux given by (5-1) and volumetric source term S (W/m^3), results in the following equations for steady-state conduction in a flat plate of thickness $2R$ ($b = 1$), a cylinder of diameter $2R$ ($b = 2$), and a sphere of diameter $2R$ ($b = 3$). The parameter b is a measure of the curvature. The thermal conductivity is constant, and there is convection at the surface, with heat-transfer coefficient h and fluid temperature T_∞.

$$\frac{d}{dr}\left(r^{b-1}\frac{dT}{dr}\right) + \frac{S}{k} r^{b-1} = 0$$

$$\frac{dT(0)}{dr} = 0 \quad \text{(symmetry condition)} \tag{5-13}$$

$$-k\frac{dT}{dr} = h[T(R) - T_\infty]$$

The solutions to (5-13), for uniform S, are

$$\frac{T(r) - T_\infty}{SR^2/k} = \frac{1}{2b}\left[1 - \left(\frac{r}{R}\right)^2\right] + \frac{1}{b\text{Bi}} \qquad \begin{cases} b = 1, \text{ plate, thickness } 2R \\ b = 2, \text{ cylinder, diameter } 2R \\ b = 3, \text{ sphere, diameter } 2R \end{cases} \tag{5-14}$$

where Bi = hR/k is the Biot number. For Bi << 1, the temperature in the solid is uniform. For Bi >> 1, the surface temperature $T(R) = T_\infty$.

Two- and Three-Dimensional Conduction Application of the law of conservation of energy to a three-dimensional solid, with the

heat flux given by (5-1) and volumetric source term S (W/m^3), results in the following equation for steady-state conduction in rectangular coordinates.

$$\frac{\partial}{\partial x}\left(k\frac{\partial T}{\partial x}\right)+\frac{\partial}{\partial y}\left(k\frac{\partial T}{\partial y}\right)+\frac{\partial}{\partial z}\left(k\frac{\partial T}{\partial z}\right)+S=0 \qquad (5\text{-}15)$$

Similar equations apply to cylindrical and spherical coordinate systems. Finite difference, finite volume, or finite element methods are generally necessary to solve (5-15). Useful introductions to these numerical techniques are given in the General References and Sec. 3. Simple forms of (5-15) (constant k, uniform S) can be solved analytically. See Arpaci, *Conduction Heat Transfer*, Addison-Wesley, 1966, p. 180, and Carslaw and Jaeger, *Conduction of Heat in Solids*, Oxford University Press, 1959. For problems involving heat flow between two surfaces, each isothermal, with all other surfaces being adiabatic, the shape factor approach is useful (Mills, *Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 164).

UNSTEADY-STATE CONDUCTION

Application of the law of conservation of energy to a three-dimensional solid, with the heat flux given by (5-1) and volumetric source term S (W/m^3), results in the following equation for unsteady-state conduction in rectangular coordinates.

$$\rho c\frac{\partial T}{\partial t}=\frac{\partial}{\partial x}\left(k\frac{\partial T}{\partial x}\right)+\frac{\partial}{\partial y}\left(k\frac{\partial T}{\partial y}\right)+\frac{\partial}{\partial z}\left(k\frac{\partial T}{\partial z}\right)+S \qquad (5\text{-}16)$$

The energy storage term is on the left-hand side, and ρ and c are the density (kg/m^3) and specific heat [J/(kg · K)]. Solutions to (5-16) are generally obtained numerically (see General References and Sec. 3). The one-dimensional form of (5-16), with constant k and no source term, is

$$\frac{\partial T}{\partial t}=\alpha\frac{\partial^2 T}{\partial x^2} \qquad (5\text{-}17)$$

where $\alpha = k/(\rho c)$ is the thermal diffusivity (m^2/s).

One-Dimensional Conduction: Lumped and Distributed Analysis The one-dimensional transient conduction equations in rectangular ($b = 1$), cylindrical ($b = 2$), and spherical ($b = 3$) coordinates, with constant k, initial uniform temperature T_i, $S = 0$, and convection at the surface with heat-transfer coefficient h and fluid temperature T_∞, are

$$\frac{\partial T}{\partial t}=\frac{\alpha}{r^{b-1}}\frac{\partial}{\partial r}\left(r^{b-1}\frac{\partial T}{\partial r}\right)\qquad \begin{cases} b=1, \text{ plate, thickness } 2R\\ b=2, \text{ cylinder, diameter } 2R\\ b=3, \text{ sphere, diameter } 2R\end{cases}$$

$$\begin{aligned}&\text{for } t<0, && T=T_i && \text{(initial temperature)}\\ &\text{at } r=0, && \frac{\partial T}{\partial r}=0 && \text{(symmetry condition)}\\ &\text{at } r=R, && -k\frac{\partial T}{\partial r}=h(T-T_\infty)\end{aligned} \qquad (5\text{-}18)$$

The solutions to (5-18) can be compactly expressed by using dimensionless variables: (1) temperature $\theta/\theta_i = [T(r,t) - T_\infty]/(T_i - T_\infty)$; (2) heat loss fraction $Q/Q_i = Q/[\rho cV(T_i - T_\infty)]$, where V is volume; (3) distance from center $\zeta = r/R$; (4) time $\text{Fo} = \alpha t/R^2$; and (5) Biot number $\text{Bi} = hR/k$. The temperature and heat loss are functions of ζ, Fo, and Bi.

When the Biot number is small, Bi < 0.2, the temperature of the solid is nearly uniform and a lumped analysis is acceptable. The solution to the lumped analysis of (5-18) is

$$\frac{\theta}{\theta_i}=\exp\left(-\frac{hA}{\rho cV}t\right)\quad\text{and}\quad \frac{Q}{Q_i}=1-\exp\left(-\frac{hA}{\rho cV}t\right) \qquad (5\text{-}19)$$

where A is the active surface area and V is the volume. The time scale for the lumped problem is

$$\tau=\frac{\rho cV}{hA} \qquad (5\text{-}20)$$

The time scale is the time required for most of the change in θ/θ_i or Q/Q_i to occur. When $t = \tau$, $\theta/\theta_i = \exp(-1) = 0.368$ and roughly two-thirds of the possible change has occurred.

When a lumped analysis is not valid (Bi > 0.2), the single-term solutions to (5-18) are convenient:

$$\frac{\theta}{\theta_i}=A_1\exp(-\delta_1^2\text{Fo})S_1(\delta_1\zeta)\quad\text{and}\quad\frac{Q}{Q_i}=1-B_1\exp(-\delta_1^2\text{Fo}) \qquad (5\text{-}21)$$

where the first Fourier coefficients A_1 and B_1 and the spatial functions S_1 are given in Table 5-1. The first eigenvalue δ_1 is given by (5-22) in conjunction with Table 5-2. The one-term solutions are accurate to within 2 percent when Fo > Fo$_c$. The values of the critical Fourier number Fo$_c$ are given in Table 5-2.

TABLE 5-1 Fourier Coefficients and Spatial Functions for Use in Eqs. (5-21)

Geometry	A_1	B_1	S_1
Plate	$\frac{2\sin\delta_1}{\delta_1+\sin\delta_1\cos\delta_1}$	$\frac{2\text{Bi}^2}{\delta_1^2(\text{Bi}^2+\text{Bi}+\delta_1^2)}$	$\cos(\delta_1\zeta)$
Cylinder	$\frac{2J_1(\delta_1)}{\delta_1[J_0^2(\delta_1)+J_1^2(\delta_1)]}$	$\frac{4\text{Bi}^2}{\delta_1^2(\delta_1^2+\text{Bi}^2)}$	$J_0(\delta_1\zeta)$
Sphere	$\frac{2\text{Bi}[\delta_1^2+(\text{Bi}-1)^2]^{1/2}}{\delta_1^2+\text{Bi}^2-\text{Bi}}$	$\frac{6\text{Bi}^2}{\delta_1^2(\delta_1^2+\text{Bi}^2-\text{Bi})}$	$\frac{\sin\delta_1\zeta}{\delta_1\zeta}$

The first eigenvalue is accurately correlated by (Yovanovich, Chap. 3 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 3.25)

$$\delta_1=\frac{\delta_{1,\infty}}{[1+(\delta_{1,\infty}/\delta_{1,0})^n]^{1/n}} \qquad (5\text{-}22)$$

Equation (5-22) gives values of δ_1 that differ from the exact values by less than 0.4 percent, and it is valid for all values of Bi. The values of $\delta_{1,\infty}$, $\delta_{1,0}$, n, and Fo$_c$ are given in Table 5-2.

Example 2: Correlation of First Eigenvalues by Eq. (5-22) As an example of the use of Eq. (5-22), suppose that we want δ_1 for the flat plate with Bi = 5. From Table 5-2, $\delta_{1,\infty} = \pi/2$, $\delta_{1,0} = \sqrt{\text{Bi}} = \sqrt{5}$, and $n = 2.139$. Equation (5-22) gives

$$\delta_1=\frac{\pi/2}{[1+(\pi/2/\sqrt{5})^{2.139}]^{1/2.139}}=1.312$$

The tabulated value is 1.3138.

Example 3: One-Dimensional, Unsteady Conduction Calculation As an example of the use of Eq. (5-21), Table 5-1, and Table 5-2, consider the cooking time required to raise the center of a spherical, 8-cm-diameter dumpling from 20 to 80°C. The initial temperature is uniform. The dumpling is heated with saturated steam at 95°C. The heat capacity, density, and thermal conductivity are estimated to be $c = 3500$ J/(kg·K), $\rho = 1000$ kg/m^3, and $k = 0.5$ W/(m·K), respectively.

Because the heat-transfer coefficient for condensing steam is of order 10^4, the Bi $\to \infty$ limit in Table 5-2 is a good choice and $\delta_1 = \pi$. Because we know the desired temperature at the center, we can calculate θ/θ_i and then solve (5-21) for the time.

$$\frac{\theta}{\theta_i}=\frac{T(0,t)-T_\infty}{T_i-T_\infty}=\frac{80-95}{20-95}=0.200$$

For Bi $\to \infty$, A_1 in Table 5-1 is 2 and for $\zeta = 0$, S_1 in Table 5-1 is 1. Equation (5-21) becomes

$$\frac{\theta}{\theta_i}=2\exp(-\pi^2\text{Fo})=2\exp\left(-\pi^2\frac{\alpha t}{R^2}\right)$$

TABLE 5-2 First Eigenvalues for Bi → 0 and Bi → ∞ and Correlation Parameter *n*

The single-term approximations apply only if Fo ≥ Fo$_c$.

Geometry	Bi → 0	Bi → ∞	n	Fo$_c$
Plate	$\delta_1\to\sqrt{\text{Bi}}$	$\delta_1\to\pi/2$	2.139	0.24
Cylinder	$\delta_1\to\sqrt{2\text{Bi}}$	$\delta_1\to 2.4048255$	2.238	0.21
Sphere	$\delta_1\to\sqrt{3\text{Bi}}$	$\delta_1\to\pi$	2.314	0.18

Solving for t gives the desired cooking time.

$$t = -\frac{R^2}{\alpha\pi^2}\ln\frac{\theta}{2\theta_i} = -\frac{(0.04\text{ m})^2}{1.43\times10^{-7}(\text{m}^2/\text{s})\pi^2}\ln\frac{0.2}{2} = 43.5\text{ min}$$

Example 4: Rule of Thumb for Time Required to Diffuse a Distance R A general rule of thumb for estimating the time required to diffuse a distance R is obtained from the one-term approximations. Consider the equation for the temperature of a flat plate of thickness $2R$ in the limit as Bi → ∞. From Table 5-2, the first eigenvalue is $\delta_1 = \pi/2$, and from Table 5-1,

$$\frac{\theta}{\theta_i} = A_1\exp\left[-\left(\frac{\pi}{2}\right)^2\frac{\alpha t}{R^2}\right]\cos\delta_1\zeta$$

When $t = R^2/\alpha$, the temperature ratio at the center of the plate ($\zeta = 0$) has decayed to $\exp(-\pi^2/4)$, or 8 percent of its initial value. We conclude that *diffusion through a distance R takes roughly R^2/α units of time,* or alternatively, *the distance diffused in time t is about $(\alpha t)^{1/2}$.*

One-Dimensional Conduction: Semi-infinite Plate Consider a semi-infinite plate with an initial uniform temperature T_i. Suppose that the temperature of the surface is suddenly raised to T_∞; that is, the heat-transfer coefficient is infinite. The unsteady temperature of the plate is

$$\frac{T(x,t)-T_\infty}{T_i - T_\infty} = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right) \tag{5-23}$$

where erf(z) is the error function. The depth to which the heat penetrates in time t is approximately $(12\alpha t)^{1/2}$.

If the heat-transfer coefficient is finite,

$$\frac{T(x,t)-T_\infty}{T_i - T_\infty}$$

$$= \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right) \tag{5-24}$$

where erfc(z) is the complementary error function. Equations (5-23) and (5-24) are both applicable to finite plates provided that their half-thickness is greater than $(12\alpha t)^{1/2}$.

Two- and Three-Dimensional Conduction The one-dimensional solutions discussed above can be used to construct solutions to multidimensional problems. The unsteady temperature of a rectangular, solid box of height, length, and width $2H$, $2L$, and $2W$, respectively, with governing equations in each direction as in (5-18), is

$$\left(\frac{\theta}{\theta_i}\right)_{2H\times2L\times2W} = \left(\frac{\theta}{\theta_i}\right)_{2H}\left(\frac{\theta}{\theta_i}\right)_{2L}\left(\frac{\theta}{\theta_i}\right)_{2W} \tag{5-25}$$

Similar products apply for solids with other geometries, e.g., semi-infinite, cylindrical rods.

HEAT TRANSFER BY CONVECTION

CONVECTIVE HEAT-TRANSFER COEFFICIENT

Convection is the transfer of energy by conduction and radiation in moving, fluid media. The motion of the fluid is an essential part of convective heat transfer. A key step in calculating the rate of heat transfer by convection is the calculation of the heat-transfer coefficient. This section focuses on the estimation of heat-transfer coefficients for natural and forced convection. The conservation equations for mass, momentum, and energy, as presented in Sec. 6, can be used to calculate the rate of convective heat transfer. Our approach in this section is to rely on correlations.

In many cases of industrial importance, heat is transferred from one fluid, through a solid wall, to another fluid. The transfer occurs in a heat exchanger. Section 11 introduces several types of heat exchangers, design procedures, overall heat-transfer coefficients, and mean temperature differences. Section 3 introduces dimensional analysis and the dimensionless groups associated with the heat-transfer coefficient.

Individual Heat-Transfer Coefficient The local rate of convective heat transfer between a surface and a fluid is given by Newton's law of cooling

$$q = h(T_{\text{surface}} - T_{\text{fluid}}) \tag{5-26}$$

where h [W/(m²·K)] is the local heat-transfer coefficient and q is the energy flux (W/m²). The definition of h is arbitrary, depending on whether the bulk fluid, centerline, free stream, or some other temperature is used for T_{fluid}. The heat-transfer coefficient may be defined on an average basis as noted below.

Consider a fluid with bulk temperature T, flowing in a cylindrical tube of diameter D, with constant wall temperature T_s. An energy balance on a short section of the tube yields

$$c_p\dot{m}\frac{dT}{dx} = \pi Dh(T_s - T) \tag{5-27}$$

where c_p is the specific heat at constant pressure [J/(kg·K)], $\dot{m}$ is the mass flow rate (kg/s), and x is the distance from the inlet. If the temperature of the fluid at the inlet is T_{in}, the temperature of the fluid at a downstream distance L is

$$\frac{T(L)-T_s}{T_{\text{in}}-T_s} = \exp\left(-\frac{\bar{h}\pi DL}{\dot{m}c_p}\right) \tag{5-28}$$

The average heat-transfer coefficient $\bar{h}$ is defined by

$$\bar{h} = \frac{1}{L}\int_0^L h\,dx \tag{5-29}$$

Overall Heat-Transfer Coefficient and Heat Exchangers A local, overall heat-transfer coefficient U for the cylindrical geometry shown in Fig. 5-2 is defined by using Eq. (5-11) as

$$\frac{\dot{Q}}{\Delta x} = \frac{T_i - T_o}{\dfrac{1}{2\pi r_1 h_i}+\dfrac{\ln(r_2/r_1)}{2\pi k}+\dfrac{1}{2\pi r_2 h_o}} = 2\pi r_1 U(T_i - T_o) \tag{5-30}$$

where Δx is a short length of tube in the axial direction. Equation (5-30) defines U by using the inside perimeter $2\pi r_1$. The outer perimeter can also be used. Equation (5-30) applies to clean tubes. Additional resistances are present in the denominator for dirty tubes (see Sec. 11).

For counterflow and parallel flow heat exchanges, with high- and low-temperature fluids (T_H and T_C) and flow directions as defined in Fig. 5-5, the total heat transfer for the exchanger is given by

$$\dot{Q} = UA\,\Delta T_{lm} \tag{5-31}$$

where A is the area for heat exchange and the log mean temperature difference ΔT_{lm} is defined as

$$\Delta T_{lm} = \frac{(T_H - T_C)_L - (T_H - T_L)_0}{\ln[(T_H - T_C)_L - (T_H - T_L)_0]} \tag{5-32}$$

Equation (5-32) applies to both counterflow and parallel flow exchangers with the nomenclature defined in Fig. 5-5. Correction factors to ΔT_{lm} for various heat exchanger configurations are given in Sec. 11.

In certain applications, the log mean temperature difference is replaced with an arithmetic mean difference:

$$\Delta T_{am} = \frac{(T_H - T_C)_L + (T_H - T_L)_0}{2} \tag{5-33}$$

Average heat-transfer coefficients are occasionally reported based on Eqs. (5-32) and (5-33) and are written as h_{lm} and h_{am}.

Representation of Heat-Transfer Coefficients Heat-transfer coefficients are usually expressed in two ways: (1) dimensionless relations and (2) dimensional equations. Both approaches are used below. The dimensionless form of the heat-transfer coefficient is the Nusselt

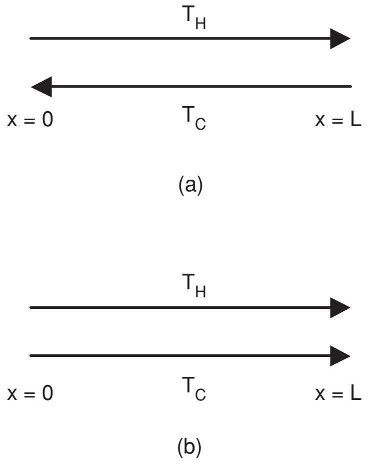

FIG. 5-5 Nomenclature for (*a*) counterflow and (*b*) parallel flow heat exchangers for use with Eq. (5-32).

number. For example, with a cylinder of diameter D in cross flow, the local Nusselt number is defined as $\mathrm{Nu}_D = hD/k$, where k is the thermal conductivity of the fluid. The subscript D is important because different characteristic lengths can be used to define Nu. The average Nusselt number is written $\overline{\mathrm{Nu}}_D = \bar{h}D/k$.

NATURAL CONVECTION

Natural convection occurs when a fluid is in contact with a solid surface of different temperature. Temperature differences create the density gradients that drive natural or free convection. In addition to the Nusselt number mentioned above, the key dimensionless parameters for natural convection include the Rayleigh number $\mathrm{Ra}_x = \beta\ \Delta T\ gx^3/\nu\alpha$ and the Prandtl number $\mathrm{Pr} = \nu/\alpha$. The properties appearing in Ra and Pr include the volumetric coefficient of expansion β (K^{-1}); the difference ΔT between the surface (T_s) and free stream (T_e) temperatures (K or °C); the acceleration of gravity g($\mathrm{m/s^2}$); a characteristic dimension x of the surface (m); the kinematic viscosity ν($\mathrm{m^2/s}$); and the thermal diffusivity α($\mathrm{m^2/s}$). The volumetric coefficient of expansion for an ideal gas is $\beta = 1/T$, where T is absolute temperature. For a given geometry,

$$\overline{\mathrm{Nu}}_x = f(\mathrm{Ra}_x, \mathrm{Pr}) \tag{5-34}$$

External Natural Flow for Various Geometries For vertical walls, Churchill and Chu [*Int. J. Heat Mass Transfer*, **18,** 1323 (1975)] recommend, for laminar and turbulent flow on isothermal, vertical walls with height L,

$$\overline{\mathrm{Nu}}_L = \left\{0.825 + \frac{0.387\mathrm{Ra}_L^{1/6}}{[1 + (0.492/\mathrm{Pr})^{9/16}]^{8/27}}\right\}^2 \tag{5-35}$$

where the fluid properties for Eq. (5-35) and $\overline{\mathrm{Nu}}_L = \bar{h}L/k$ are evaluated at the film temperature $T_f = (T_s + T_e)/2$. This correlation is valid for all Pr and Ra_L. For vertical cylinders with boundary layer thickness much less than their diameter, Eq. (5-35) is applicable. An expression for uniform heating is available from the same reference.

For laminar and turbulent flow on isothermal, horizontal cylinders of diameter D, Churchill and Chu [*Int. J. Heat Mass Transfer*, **18,** 1049 (1975)] recommend

$$\overline{\mathrm{Nu}}_L = \left\{0.60 + \frac{0.387\mathrm{Ra}_D^{1/6}}{[1 + (0.559/\mathrm{Pr})^{9/16}]^{8/27}}\right\}^2 \tag{5-36}$$

Fluid properties for (5-36) should be evaluated at the film temperature $T_f = (T_s + T_e)/2$. This correlation is valid for all Pr and Ra_D.

For horizontal flat surfaces, the characteristic dimension for the correlations is [Goldstein, Sparrow, and Jones, *Int. J. Heat Mass Transfer*, **16,** 1025–1035 (1973)]

$$L = \frac{A}{p} \tag{5-37}$$

where A is the area of the surface and p is the perimeter. With hot surfaces facing upward, or cold surfaces facing downward [Lloyd and Moran, ASME Paper 74-WA/HT-66 (1974)],

$$\overline{\mathrm{Nu}}_L = \begin{cases} 0.54\mathrm{Ra}_L^{1/4} & 10^4 < \mathrm{Ra}_L < 10^7 \quad (5\text{-}38) \\ 0.15\mathrm{Ra}_L^{1/3} & 10^7 < \mathrm{Ra}_L < 10^{10} \quad (5\text{-}39) \end{cases}$$

and for hot surfaces facing downward, or cold surfaces facing upward,

$$\overline{\mathrm{Nu}}_L = 0.27\mathrm{Ra}_L^{1/4} \qquad 10^5 < \mathrm{Ra}_L < 10^{10} \tag{5-40}$$

Fluid properties for Eqs. (5-38) to (5-40) should be evaluated at the film temperature $T_f = (T_s + T_e)/2$.

Simultaneous Heat Transfer by Radiation and Convection Simultaneous heat transfer by radiation and convection is treated per the procedure outlined in Examples 1 and 5. A radiative heat-transfer coefficient h_R is defined by (5-12).

Mixed Forced and Natural Convection Natural convection is commonly assisted or opposed by forced flow. These situations are discussed, e.g., by Mills (*Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 340) and Raithby and Hollands (Chap. 4 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 4.73).

Enclosed Spaces The rate of heat transfer across an enclosed space is described in terms of a heat-transfer coefficient based on the temperature difference between two surfaces:

$$\bar{h} = \frac{\dot{Q}/A}{T_H - T_C} \tag{5-41}$$

For rectangular cavities, the plate spacing between the two surfaces L is the characteristic dimension that defines the Nusselt and Rayleigh numbers. The temperature difference in the Rayleigh number, $\mathrm{Ra}_L = \beta\,\Delta T\,gL^3/\nu\alpha$ is $\Delta T = T_H - T_C$.

For a horizontal rectangular cavity heated from below, the onset of advection requires $\mathrm{Ra}_L > 1708$. Globe and Dropkin [*J. Heat Transfer*, **81**, 24–28 (1959)] propose the correlation

$$\overline{\mathrm{Nu}}_L = 0.069\mathrm{Ra}_L^{1/3}\mathrm{Pr}^{0.074} \qquad 3 \times 10^5 < \mathrm{Ra}_L < 7 \times 10^9 \tag{5-42}$$

All properties in (5-42) are calculated at the average temperature $(T_H + T_C)/2$.

For vertical rectangular cavities of height H and spacing L, with $\mathrm{Pr} \approx 0.7$ (gases) and $40 < H/L < 110$, the equation of Shewen et al. [*J. Heat Transfer*, **118,** 993–995 (1996)] is recommended:

$$\overline{\mathrm{Nu}}_L = \left\{1 + \left[\frac{0.0665\mathrm{Ra}_L^{1/3}}{1 + (9000/\mathrm{Ra}_L)^{1.4}}\right]^2\right\}^{1/2} \qquad \mathrm{Ra}_L < 10^6 \tag{5-43}$$

All properties in (5-43) are calculated at the average temperature $(T_H + T_C)/2$.

Example 5: Comparison of the Relative Importance of Natural Convection and Radiation at Room Temperature Estimate the heat losses by natural convection and radiation for an undraped person standing in still air. The temperatures of the air, surrounding surfaces, and skin are 19, 15, and 35°C, respectively. The height and surface area of the person are 1.8 m and 1.8 m². The emissivity of the skin is 0.95.

We can estimate the Nusselt number by using (5-35) for a vertical, flat plate of height $L = 1.8$ m. The film temperature is $(19 + 35)/2 = 27$°C. The Rayleigh number, evaluated at the film temperature, is

$$\mathrm{Ra}_L = \frac{\beta\,\Delta T\,gL^3}{\nu\alpha} = \frac{(1/300)(35 - 19)9.81(1.8)^3}{1.589 \times 10^{-5}(2.25 \times 10^{-5})} = 8.53 \times 10^9$$

From (5-35) with $\mathrm{Pr} = 0.707$, the Nusselt number is 240 and the average heat-transfer coefficient due to natural convection is

$$\bar{h} = \frac{k}{L}\overline{\mathrm{Nu}}_L = \frac{0.0263}{1.8}(240) = 3.50\,\frac{\mathrm{W}}{\mathrm{m^2{\cdot}K}}$$

The radiative heat-transfer coefficient is given by (5-12):

$$h_R = \varepsilon_{skin}\sigma(T_{skin}^2 + T_{sur}^2)(T_{skin} + T_{sur})$$
$$= 0.95(5.67 \times 10^{-8})(308^2 + 288^2)(308 + 288) = 5.71 \frac{W}{m^2{\cdot}K}$$

The total rate of heat loss is

$$\dot{Q} = \bar{h}A(T_{skin} - T_{air}) + \bar{h}_R A(T_{skin} - T_{sur})$$
$$= 3.50(1.8)(35 - 19) + 5.71(1.8)(35 - 15) = 306 \text{ W}$$

At these conditions, radiation is nearly twice as important as natural convection.

FORCED CONVECTION

Forced convection heat transfer is probably the most common mode in the process industries. Forced flows may be internal or external. This subsection briefly introduces correlations for estimating heat-transfer coefficients for flows in tubes and ducts; flows across plates, cylinders, and spheres; flows through tube banks and packed beds; heat transfer to nonevaporating falling films; and rotating surfaces. Section 11 introduces several types of heat exchangers, design procedures, overall heat-transfer coefficients, and mean temperature differences.

Flow in Round Tubes In addition to the Nusselt ($Nu_D = hD/k$) and Prandtl ($Pr = \nu/\alpha$) numbers introduced above, the key dimensionless parameter for forced convection in round tubes of diameter D is the Reynolds number $Re = GD/\mu$, where G is the mass velocity $G = \dot{m}/A_c$ and A_c is the cross-sectional area $A_c = \pi D^2/4$. For internal flow in a tube or duct, the heat-transfer coefficient is defined as

$$q = h(T_s - T_b) \tag{5-44}$$

where T_b is the bulk or mean temperature at a given cross section and T_s is the corresponding surface temperature.

For laminar flow ($Re_D < 2100$) that is fully developed, both hydrodynamically and thermally, the Nusselt number has a constant value. For a uniform wall temperature, $Nu_D = 3.66$. For a uniform heat flux through the tube wall, $Nu_D = 4.36$. In both cases, the thermal conductivity of the fluid in Nu_D is evaluated at T_b. The distance x required for a fully developed laminar velocity profile is given by $[(x/D)/Re_D] \approx 0.05$. The distance x required for fully developed velocity and thermal profiles is obtained from $[(x/D)/(Re_D\, Pr)] \approx 0.05$.

For a constant wall temperature, a fully developed laminar velocity profile, and a developing thermal profile, the average Nusselt number is estimated by [Hausen, *Allg. Waermetech.*, **9,** 75 (1959)]

$$\overline{Nu}_D = 3.66 + \frac{0.0668(D/L)\, Re_D\, Pr}{1 + 0.04[(D/L)\, Re_D\, Pr]^{2/3}} \tag{5-45}$$

For large values of L, Eq. (5-45) approaches $Nu_D = 3.66$. Equation (5-45) also applies to developing velocity and thermal profiles conditions if Pr >>1. The properties in (5-45) are evaluated at the bulk mean temperature

$$\overline{T}_b = (T_{b,in} + T_{b,out})/2 \tag{5-46}$$

For a constant wall temperature with developing laminar velocity and thermal profiles, the average Nusselt number is approximated by [Sieder and Tate, *Ind. Eng. Chem.*, **28,** 1429 (1936)]

$$\overline{Nu}_D = 1.86\left(\frac{D}{L}\, Re_D\, Pr\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.14} \tag{5-47}$$

The properties, except for μ_s, are evaluated at the bulk mean temperature per (5-46) and $0.48 < Pr < 16{,}700$ and $0.0044 < \mu_b/\mu_s < 9.75$.

For fully developed flow in the transition region between laminar and turbulent flow, and for fully developed turbulent flow, Gnielinski's [*Int. Chem. Eng.*, **16,** 359 (1976)] equation is recommended:

$$Nu_D = \frac{(f/2)(Re_D - 1000)(Pr)}{1 + 12.7(f/2)^{1/2}(Pr^{2/3} - 1)} K \tag{5-48}$$

where $0.5 < Pr < 10^5$, $2300 < Re_D < 10^6$, $K = (Pr_b/Pr_s)^{0.11}$ for liquids ($0.05 < Pr_b/Pr_s < 20$), and $K = (T_b/T_s)^{0.45}$ for gases ($0.5 < T_b/T_s < 1.5$). The factor K corrects for variable property effects. For smooth tubes, the Fanning friction factor f is given by

$$f = 0.25(0.790 \ln Re_D - 1.64)^{-2} \qquad 2300 < Re_D < 10^6 \tag{5-49}$$

TABLE 5-3 Effect of Entrance Configuration on Values of *C* and *n* in Eq. (5-53) for Pr ≈ 1 (Gases and Other Fluids with Pr about 1)

Entrance configuration	C	n
Long calming section	0.9756	0.760
Open end, 90° edge	2.4254	0.676
180° return bend	0.9759	0.700
90° round bend	1.0517	0.629
90° elbow	2.0152	0.614

For rough pipes, approximate values of Nu_D are obtained if f is estimated by the Moody diagram of Sec. 6. Equation (5-48) is corrected for entrance effects per (5-53) and Table 5-3. Sieder and Tate [*Ind. Eng. Chem.*, **28,** 1429 (1936)] recommend a simpler but less accurate equation for fully developed turbulent flow

$$Nu_D = 0.027\, Re_D^{4/5}\, Pr^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.14} \tag{5-50}$$

where $0.7 < Pr < 16{,}700$, $Re_D < 10{,}000$, and $L/D > 10$. Equations (5-48) and (5-50) apply to both constant temperature and uniform heat flux along the tube. The properties are evaluated at the bulk temperature T_b, except for μ_s, which is at the temperature of the tube. For L/D greater than about 10, Eqs. (5-48) and (5-50) provide an estimate of $\overline{Nu}_D$. In this case, the properties are evaluated at the bulk mean temperature per (5-46). More complicated and comprehensive predictions of fully developed turbulent convection are available in Churchill and Zajic [*AIChE J.*, **48,** 927 (2002)] and Yu, Ozoe, and Churchill [*Chem. Eng. Science*, **56,** 1781 (2001)].

For fully developed turbulent flow of liquid metals, the Nusselt number depends on the wall boundary condition. For a constant wall temperature [Notter and Sleicher, *Chem. Eng. Science*, **27,** 2073 (1972)],

$$Nu_D = 4.8 + 0.0156\, Re_D^{0.85}\, Pr^{0.93} \tag{5-51}$$

while for a uniform wall heat flux,

$$Nu_D = 6.3 + 0.0167\, Re_D^{0.85}\, Pr^{0.93} \tag{5-52}$$

In both cases the properties are evaluated at T_b and $0.004 < Pr < 0.01$ and $10^4 < Re_D < 10^6$.

Entrance effects for turbulent flow with simultaneously developing velocity and thermal profiles can be significant when $L/D < 10$. Shah and Bhatti correlated entrance effects for gases ($Pr \approx 1$) to give an equation for the average Nusselt number in the entrance region (in Kaka, Shah, and Aung, eds., *Handbook of Single-Phase Convective Heat Transfer*, Chap. 3, Wiley-Interscience, 1987).

$$\frac{\overline{Nu}_D}{Nu_D} = 1 + \frac{C}{(x/D)^n} \tag{5-53}$$

where Nu_D is the fully developed Nusselt number and the constants C and n are given in Table 5-3 (Ebadian and Dong, Chap. 5 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 5.31). The tube entrance configuration determines the values of C and n as shown in Table 5-3.

Flow in Noncircular Ducts The length scale in the Nusselt and Reynolds numbers for noncircular ducts is the hydraulic diameter, $D_h = 4A_c/p$, where A_c is the cross-sectional area for flow and p is the wetted perimeter. Nusselt numbers for fully developed laminar flow in a variety of noncircular ducts are given by Mills (*Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 307). For turbulent flows, correlations for round tubes can be used with D replaced by D_h.

For annular ducts, the accuracy of the Nusselt number given by (5-48) is improved by the following multiplicative factors [Petukhov and Roizen, *High Temp.*, **2,** 65 (1964)].

Inner tube heated $\quad 0.86\left(\dfrac{D_i}{D_o}\right)^{-0.16}$

Outer tube heated $\quad 1 - 0.14\left(\dfrac{D_i}{D_o}\right)^{0.6}$

where D_i and D_o are the inner and outer diameters, respectively.

Example 6: Turbulent Internal Flow Air at 300 K, 1 bar, and 0.05 kg/s enters a channel of a plate-type heat exchanger (Mills, *Heat Transfer*, 2d ed., Prentice-Hall, 1999) that measures 1 cm wide, 0.5 m high, and 0.8 m long. The walls are at 600 K, and the mass flow rate is 0.05 kg/s. The entrance has a 90° edge. We want to estimate the exit temperature of the air.

Our approach will use (5-48) to estimate the average heat-transfer coefficient, followed by application of (5-28) to calculate the exit temperature. We assume ideal gas behavior and an exit temperature of 500 K. The estimated bulk mean temperature of the air is, by (5-46), 400 K. At this temperature, the properties of the air are Pr = 0.690, $\mu = 2.301 \times 10^{-5}$ kg/(m·s), $k = 0.0338$ W/(m·K), and $c_p = 1014$ J/(kg·K).

We start by calculating the hydraulic diameter $D_h = 4A_c/p$. The cross-sectional area for flow A_c is 0.005 m^2, and the wetted perimeter p is 1.02 m. The hydraulic diameter $D_h = 0.01961$ m. The Reynolds number is

$$\text{Re}_{D_h} = \frac{\dot{m}D_h}{A_c\mu} = \frac{0.05(0.01961)}{0.005(2.301 \times 10^{-5})} = 8521$$

The flow is in the transition region, and Eqs. (5-49) and (5-48) apply:

$$f = 0.25(0.790 \ln \text{Re}_{D_h} - 1.64)^{-2} = 0.25(0.790 \ln 8521 - 1.64)^{-2} = 0.008235$$

$$\text{Nu}_D = \frac{(f/2)(\text{Re}_D - 1000)(\text{Pr})}{1 + 12.7(f/2)^{1/2}(\text{Pr}^{2/3} - 1)}\, K$$

$$= \frac{(0.008235/2)(8521 - 1000)(0.690)}{1 + 12.7(0.008235/2)^{1/2}(0.690^{2/3} - 1)}\left(\frac{400}{600}\right)^{0.45} = 21.68$$

Entrance effects are included by using (5-53) for an open end, 90° edge:

$$\overline{\text{Nu}}_D = \left[1 + \frac{C}{(x/D)^n}\right]\text{Nu}_D = \left[1 + \frac{2.4254}{(0.8/0.01961)^{0.676}}\right](21.68) = 25.96$$

The average heat-transfer coefficient becomes

$$\bar{h} = \frac{k}{D_h}\overline{\text{Nu}}_D = \frac{0.0338}{0.01961}(25.96) = 44.75\ \frac{\text{W}}{\text{m}^2\cdot\text{K}}$$

The exit temperature is calculated from (5-28):

$$T(L) = T_s - (T_s - T_{\text{in}})\exp\left(-\frac{\bar{h}pL}{\dot{m}c_P}\right)$$

$$= 600 - (600 - 300)\exp\left[-\frac{44.75(1.02)0.8}{0.05(1014)}\right] = 450\text{ K}$$

We conclude that our estimated exit temperature of 500 K is too high. We could repeat the calculations, using fluid properties evaluated at a revised bulk mean temperature of 375 K.

Coiled Tubes For turbulent flow inside helical coils, with tube inside radius a and coil radius R, the Nusselt number for a straight tube Nu_s is related to that for a coiled tube Nu_c by (Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 5.90)

$$\frac{\text{Nu}_c}{\text{Nu}_s} = 1.0 + 3.6\left(1 - \frac{a}{R}\right)\left(\frac{a}{R}\right)^{0.8} \tag{5-54}$$

where $2 \times 10^4 < \text{Re}_D < 1.5 \times 10^5$ and $5 < R/a < 84$. For lower Reynolds numbers ($1.5 \times 10^3 < \text{Re}_D < 2 \times 10^4$), the same source recommends

$$\frac{\text{Nu}_c}{\text{Nu}_s} = 1.0 + 3.4\frac{a}{R} \tag{5-55}$$

External Flows For a single cylinder in cross flow, Churchill and Bernstein recommend [*J. Heat Transfer*, **99,** 300 (1977)]

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62\,\text{Re}_D^{1/2}\,\text{Pr}^{1/3}}{[1 + (0.4/\text{Pr})^{2/3}]^{1/4}}\left[1 + \left(\frac{\text{Re}_D}{282{,}000}\right)^{5/8}\right]^{4/5} \tag{5-56}$$

where $\overline{\text{Nu}}_D = \bar{h}D/k$. Equation (5-56) is for all values of Re_D and Pr, provided that $\text{Re}_D\text{Pr} > 0.4$. The fluid properties are evaluated at the film temperature $(T_e + T_s)/2$, where T_e is the free-stream temperature and T_s is the surface temperature. Equation (5-56) also applies to the uniform heat flux boundary condition provided $\bar{h}$ is based on the perimeter-averaged temperature difference between T_s and T_e.

For an isothermal spherical surface, Whitaker recommends [*AIChE*, **18,** 361 (1972)]

$$\overline{\text{Nu}}_D = 2 + \left(0.4\text{Re}_D^{1/2} + 0.06\text{Re}_D^{2/3}\right)\text{Pr}^{0.4}\left(\frac{\mu_e}{\mu_s}\right)^{1/4} \tag{5-57}$$

This equation is based on data for $0.7 < \text{Pr} < 380$, $3.5 < \text{Re}_D < 8 \times 10^4$, and $1 < (\mu_e/\mu_s) < 3.2$. The properties are evaluated at the free-stream temperature T_e, with the exception of μ_s, which is evaluated at the surface temperature T_s.

The average Nusselt number for laminar flow over an isothermal flat plate of length x is estimated from [Churchill and Ozoe, *J. Heat Transfer*, **95,** 416 (1973)]

$$\overline{\text{Nu}}_x = \frac{1.128\,\text{Pr}^{1/2}\,\text{Re}_x^{1/2}}{[1 + (0.0468/\text{Pr})^{2/3}]^{1/4}} \tag{5-58}$$

This equation is valid for all values of Pr as long as $\text{Re}_x\,\text{Pr} > 100$ and $\text{Re}_x < 5 \times 10^5$. The fluid properties are evaluated at the film temperature $(T_e + T_s)/2$, where T_e is the free-stream temperature and T_s is the surface temperature. For a uniformly heated flat plate, the local Nusselt number is given by [Churchill and Ozoe, *J. Heat Transfer*, **95,** 78 (1973)]

$$\text{Nu}_x = \frac{0.886\,\text{Pr}^{1/2}\,\text{Re}_x^{1/2}}{[1 + (0.0207/\text{Pr})^{2/3}]^{1/4}} \tag{5-59}$$

where again the properties are evaluated at the film temperature.

The average Nusselt number for turbulent flow over a smooth, isothermal flat plate of length x is given by (Mills, *Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 315)

$$\overline{\text{Nu}}_x = 0.664\,\text{Re}_{\text{cr}}^{1/2}\,\text{Pr}^{1/3} + 0.036\,\text{Re}_x^{0.8}\,\text{Pr}^{0.43}\left[1 - \left(\frac{\text{Re}_{\text{cr}}}{\text{Re}_x}\right)^{0.8}\right] \tag{5-60}$$

The critical Reynolds number Re_{cr} is typically taken as 5×10^5, $\text{Re}_{\text{cr}} < \text{Re}_x < 3 \times 10^7$, and $0.7 < \text{Pr} < 400$. The fluid properties are evaluated at the film temperature $(T_e + T_s)/2$, where T_e is the free-stream temperature and T_s is the surface temperature. Equation (5-60) also applies to the uniform heat flux boundary condition provided $\bar{h}$ is based on the average temperature difference between T_s and T_e.

Flow-through Tube Banks Aligned and staggered tube banks are sketched in Fig. 5-6. The tube diameter is D, and the transverse and longitudinal pitches are S_T and S_L, respectively. The fluid velocity upstream

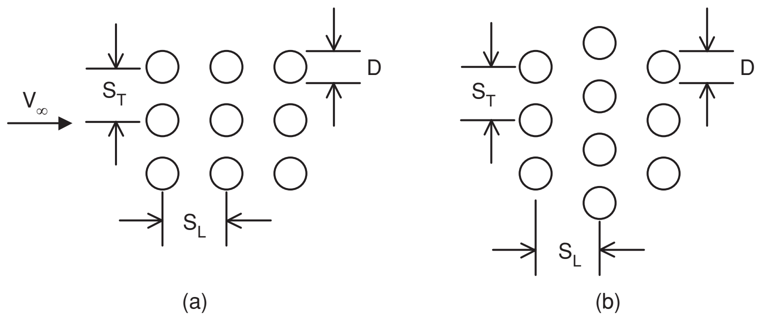

FIG. 5-6 *(a)* Aligned and *(b)* staggered tube bank configurations. The fluid velocity upstream of the tubes is V_∞.

of the tubes is V_∞. To estimate the overall heat-transfer coefficient for the tube bank, Mills proceeds as follows (*Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 348). The Reynolds number for use in (5-56) is recalculated with an effective average velocity in the space between adjacent tubes:

$$\frac{\overline{V}}{V_\infty} = \frac{S_T}{S_T - (\pi/4)D} \tag{5-61}$$

The heat-transfer coefficient increases from row 1 to about row 5 of the tube bank. The average Nusselt number for a tube bank with 10 or more rows is

$$\overline{\text{Nu}}_D^{10+} = \Phi\overline{\text{Nu}}_D^1 \tag{5-62}$$

where Φ is an arrangement factor and $\overline{\text{Nu}}_D^1$ is the Nusselt number for the first row, calculated by using the velocity in (5-61). The arrangement factor is calculated as follows. Define dimensionless pitches as $P_T = S_T/D$ and P_L/D and calculate a factor ψ as follows.

$$\psi = \begin{cases} 1 - \dfrac{\pi}{4P_T} & \text{if } P_L \geq 1 \\ 1 - \dfrac{\pi}{4P_TP_L} & \text{if } P_L < 1 \end{cases} \tag{5-63}$$

The arrangement factors are

$$\Phi_{\text{aligned}} = 1 + \frac{0.7}{\psi^{1.5}}\,\frac{S_L/S_T - 0.3}{(S_L/S_T + 0.7)^2} \tag{5-64}$$

$$\Phi_{\text{staggered}} = 1 + \frac{2}{3P_L} \tag{5-65}$$

If there are fewer than 10 rows,

$$\overline{\text{Nu}}_D = \frac{1 + (N-1)\Phi}{N}\,\overline{\text{Nu}}_D^1 \tag{5-66}$$

where N is the number of rows.

The fluid properties for gases are evaluated at the average mean film temperature $[(T_{\text{in}} + T_{\text{out}})/2 + T_s]/2$. For liquids, properties are evaluated at the bulk mean temperature $(T_{\text{in}} + T_{\text{out}})/2$, with a Prandtl number correction $(\text{Pr}_b/\text{Pr}_s)^{0.11}$ for cooling and $(\text{Pr}_b/\text{Pr}_s)^{0.25}$ for heating.

Falling Films When a liquid is distributed uniformly around the periphery at the top of a vertical tube (either inside or outside) and allowed to fall down the tube wall by the influence of gravity, the fluid does not fill the tube but rather flows as a thin layer. Similarly, when a liquid is applied uniformly to the outside and top of a horizontal tube, it flows in layer form around the periphery and falls off the bottom. In both these cases the mechanism is called gravity flow of liquid layers or falling films.

For the turbulent flow of **water** in layer form down the walls of **vertical tubes** the dimensional equation of McAdams, Drew, and Bays [*Trans. Am. Soc. Mech. Eng.,* **62,** 627 (1940)] is recommended:

$$h_{lm} = b\Gamma^{1/3} \tag{5-67}$$

where $b = 9150$ (SI) or 120 (U.S. Customary) and is based on values of $\Gamma = W_F = \dot{M}/\pi D$ ranging from 0.25 to 6.2 kg/(m·s) [600 to 15,000 lb/(h·ft)] of wetted perimeter. This type of water flow is used in vertical vapor-in-shell ammonia condensers, acid coolers, cycle water coolers, and other process-fluid coolers.

The following dimensional equations may be used for **any liquid** flowing in layer form down **vertical surfaces:**

$$\text{For}\quad \frac{4\Gamma}{\mu} > 2100 \quad h_{lm} = 0.01\left(\frac{k^3\rho^2 g}{\mu^2}\right)^{1/3}\left(\frac{c\mu}{k}\right)^{1/3}\left(\frac{4\Gamma}{\mu}\right)^{1/3} \tag{5-68a}$$

$$\text{For}\quad \frac{4\Gamma}{\mu} < 2100 \quad h_{am} = 0.50\left(\frac{k^2\rho^{4/3}cg^{2/3}}{L\mu^{1/3}}\right)^{1/3}\left(\frac{\mu}{\mu_w}\right)^{1/4}\left(\frac{4\Gamma}{\mu}\right)^{1/9} \tag{5-68b}$$

Equation (5-68*b*) is based on the work of Bays and McAdams [*Ind. Eng. Chem.,* **29,** 1240 (1937)]. The significance of the term L is not clear. When $L = 0$, the coefficient is definitely not infinite. When L is large and the fluid temperature has not yet closely approached the wall temperature, it does not appear that the coefficient should necessarily decrease. Within the finite limits of 0.12 to 1.8 m (0.4 to 6 ft), this equation should give results of the proper order of magnitude.

For falling films applied to the **outside of horizontal tubes,** the Reynolds number rarely exceeds 2100. Equations may be used for falling films on the outside of the tubes by substituting $\pi D/2$ for L.

For **water** flowing over a **horizontal tube,** data for several sizes of pipe are roughly correlated by the dimensional equation of McAdams, Drew, and Bays [*Trans. Am. Soc. Mech. Eng.,* **62,** 627 (1940)].

$$h_{am} = b(\Gamma/D_0)^{1/3} \tag{5-69}$$

where $b = 3360$ (SI) or 65.6 (U.S. Customary) and Γ ranges from 0.94 to 4 kg/(m·s) [100 to 1000 lb/(h·ft)].

Falling films are also used for evaporation in which the film is both entirely or partially evaporated (juice concentration). This principle is also used in crystallization (freezing).

The advantage of high coefficient in falling-film exchangers is partially offset by the difficulties involved in distribution of the film, maintaining complete wettability of the tube, and pumping costs required to lift the liquid to the top of the exchanger.

Finned Tubes (Extended Surface) When the heat-transfer coefficient on the outside of a metal tube is much lower than that on the inside, as when steam condensing in a pipe is being used to heat air, externally finned (or extended) heating surfaces are of value in increasing substantially the rate of heat transfer per unit length of tube. The data on extended heating surfaces, for the case of air flowing outside and at right angles to the axes of a bank of finned pipes, can be represented approximately by the dimensional equation derived from

$$h_f = b\,\frac{V_F^{0.6}}{D_0^{0.4}}\left(\frac{p'}{p' - D_0}\right)^{0.6} \tag{5-70}$$

where $b = 5.29$ (SI) or $(5.39)(10^{-3})$ (U.S. Customary); h_f is the coefficient of heat transfer on the air side; V_F is the face velocity of the air; p' is the center-to-center spacing, m, of the tubes in a row; and D_0 is the outside diameter, m, of the bare tube (diameter at the root of the fins).

In atmospheric air-cooled finned tube exchangers, the air-film coefficient from Eq. (5-70) is sometimes converted to a value based on outside bare surface as follows:

$$h_{fo} = h_f\,\frac{A_f + A_{uf}}{A_{of}} = h_f\,\frac{A_T}{A_o} \tag{5-71}$$

in which h_{fo} is the air-film coefficient based on external bare surface; h_f is the air-film coefficient based on total external surface; A_T is total external surface, and A_o is external bare surface of the unfinned tube; A_f is the area of the fins; A_{uf} is the external area of the unfinned portion of the tube; and A_{of} is area of tube before fins are attached.

Fin efficiency is defined as the ratio of the mean temperature difference from surface to fluid divided by the temperature difference from fin to fluid at the base or root of the fin. Graphs of fin efficiency for extended surfaces of various types are given by Gardner [*Trans. Am. Soc. Mech. Eng.,* **67,** 621 (1945)].

Heat-transfer coefficients for finned tubes of various types are given in a series of papers [*Trans. Am. Soc. Mech. Eng.,* **67,** 601 (1945)].

For flow of air normal to fins in the form of **short strips or pins,** Norris and Spofford [*Trans. Am. Soc. Mech. Eng.,* **64,** 489 (1942)] correlate their results for air by the dimensionless equation of Pohlhausen:

$$\frac{h_m}{c_pG_{\text{max}}}\left(\frac{c_p\mu}{k}\right)^{2/3} = 1.0\left(\frac{z_pG_{\text{max}}}{\mu}\right)^{-0.5} \tag{5-72}$$

for values of z_pG_{max}/μ ranging from 2700 to 10,000.

For the general case, the treatment suggested by Kern (*Process Heat Transfer,* McGraw-Hill, New York, 1950, p. 512) is recommended. Because of the wide variations in fin-tube construction, it is convenient to convert all coefficients to values based on the inside bare surface of the tube. Thus to convert the coefficient based on outside area (finned side) to a value based on inside area Kern gives the following relationship:

$$h_{fi} = (\Omega A_f + A_o)(h_f/A_i) \tag{5-73}$$

in which h_{fi} is the effective outside coefficient based on the inside area, h_f is the outside coefficient calculated from the applicable equation for bare tubes, A_f is the surface area of the fins, A_o is the surface area on the outside of the tube which is not finned, A_i is the inside area of the tube, and Ω is the fin efficiency defined as

$$\Omega = (\tanh mb_f)/mb_f \tag{5-74}$$

in which

$$m = (h_f p_f / k a_x)^{1/2} \quad \text{m}^{-1}\ (\text{ft}^{-1}) \tag{5-75}$$

and b_f = height of fin. The other symbols are defined as follows: p_f is the perimeter of the fin, a_x is the cross-sectional area of the fin, and k is the thermal conductivity of the material from which the fin is made.

Fin efficiencies and fin dimensions are available from manufacturers. Ratios of finned to inside surface are usually available so that the terms A_f, A_o, and A_i may be obtained from these ratios rather than from the total surface areas of the heat exchangers.

JACKETS AND COILS OF AGITATED VESSELS

See Secs. 11 and 18.

NONNEWTONIAN FLUIDS

A wide variety of nonnewtonian fluids are encountered industrially. They may exhibit Bingham-plastic, pseudoplastic, or dilatant behavior and may or may not be thixotropic. For design of equipment to handle or process nonnewtonian fluids, the properties must usually be measured experimentally, since no generalized relationships exist to predict the properties or behavior of the fluids. Details of handling nonnewtonian fluids are described completely by Skelland (*Non-Newtonian Flow and Heat Transfer,* Wiley, New York, 1967). The generalized shear-stress rate-of-strain relationship for nonnewtonian fluids is given as

$$n' = \frac{d \ln (D\,\Delta P/4L)}{d \ln (8V/D)} \tag{5-76}$$

as determined from a plot of shear stress versus velocity gradient.

For **circular tubes,** Gz > 100, n' > 0.1, and laminar flow

$$\text{Nu}_{lm} = 1.75\,\delta_s^{1/3}\text{Gz}^{1/3} \tag{5-77}$$

where $\delta_s = (3n' + 1)/4n'$. When natural convection effects are considered, Metzer and Gluck [*Chem. Eng. Sci.,* **12,** 185 (1960)] obtained the following for **horizontal tubes:**

$$\text{Nu}_{lm} = 1.75\,\delta_s^{1/3}\left[\text{Gz} + 12.6\left(\frac{\text{Pr}\,\text{Gr}D}{L}\right)^{0.4}\right]^{1/3}\left(\frac{\gamma_b}{\gamma_w}\right)^{0.14} \tag{5-78}$$

where properties are evaluated at the wall temperature, i.e., $\gamma = g_c K' 8^{n'-1}$ and $\tau_w = K'(8V/D)^{n'}$.

Metzner and Friend [*Ind. Eng. Chem.,* **51,** 879 (1959)] present relationships for turbulent heat transfer with nonnewtonian fluids. Relationships for heat transfer by natural convection and through laminar boundary layers are available in Skelland's book (op. cit.).

HEAT TRANSFER WITH CHANGE OF PHASE

In any operation in which a material undergoes a change of phase, provision must be made for the addition or removal of heat to provide for the latent heat of the change of phase plus any other sensible heating or cooling that occurs in the process. Heat may be transferred by any one or a combination of the three modes—conduction, convection, and radiation. The process involving change of phase involves mass transfer simultaneous with heat transfer.

CONDENSATION

Condensation Mechanisms Condensation occurs when a saturated vapor comes in contact with a surface whose temperature is below the saturation temperature. Normally a film of condensate is formed on the surface, and the thickness of this film, per unit of breadth, increases with increase in extent of the surface. This is called **film-type condensation.**

Another type of condensation, called **dropwise,** occurs when the wall is not uniformly wetted by the condensate, with the result that the condensate appears in many small droplets at various points on the surface. There is a growth of individual droplets, a coalescence of adjacent droplets, and finally a formation of a rivulet. Adhesional force is overcome by gravitational force, and the rivulet flows quickly to the bottom of the surface, capturing and absorbing all droplets in its path and leaving dry surface in its wake.

Film-type condensation is more common and more dependable. Dropwise condensation normally needs to be promoted by introducing an impurity into the vapor stream. Substantially higher (6 to 18 times) coefficients are obtained for dropwise condensation of steam, but design methods are not available. Therefore, the development of equations for condensation will be for the film type only.

The physical properties of the liquid, rather than those of the vapor, are used for determining the coefficient for condensation. Nusselt [*Z. Ver. Dtsch. Ing.,* **60,** 541, 569 (1916)] derived theoretical relationships for predicting the coefficient of heat transfer for condensation of a pure saturated vapor. A number of simplifying assumptions were used in the derivation.

The **Reynolds number** of the condensate film (falling film) is $4\Gamma/\mu$, where Γ is the weight rate of flow (loading rate) of condensate per unit perimeter kg/(s·m) [lb/(h·ft)]. The thickness of the condensate film for Reynolds number less than 2100 is $(3\mu\Gamma/\rho^2 g)^{1/3}$.

Condensation Coefficients

Vertical Tubes For the following cases Reynolds number < 2100 and is calculated by using $\Gamma = W_F/\pi D$. The **Nusselt equation** for the heat-transfer coefficient for condensate films may be written in the following ways (using liquid physical properties and where L is the cooled length and Δt is $t_{sv} - t_s$):

Nusselt type:

$$\frac{hL}{k} = 0.943\left(\frac{L^3\rho^2 g\lambda}{k\mu\,\Delta t}\right)^{1/4} = 0.925\left(\frac{L^3\rho^2 g}{\mu\Gamma}\right)^{1/3} \tag{5-79*}$$

Dimensional:

$$h = b(k^3\rho^2 D/\mu_b W_F)^{1/3} \tag{5-80*}$$

where b = 127 (SI) or 756 (U.S. Customary). For steam at atmospheric pressure, k = 0.682 J/(m·s·K) [0.394 Btu/(h·ft·°F)], ρ = 960 kg/m³ (60 lb/ft³), $\mu_b = (0.28)(10^{-3})$ Pa·s (0.28 cP),

$$h = b(D/W_F)^{1/3} \tag{5-81}$$

where b = 2954 (SI) or 6978 (U.S. Customary). For organic vapors at normal boiling point, k = 0.138 J/(m·s·K) [0.08 Btu/(h·ft·°F)], ρ = 720 kg/m³ (45 lb/ft³), $\mu_b = (0.35)(10^{-3})$ Pa·s (0.35 cP),

$$h = b(D/W_F)^{1/3} \tag{5-82}$$

where b = 457 (SI) or 1080 (U.S. Customary).

Horizontal Tubes For the following cases Reynolds number < 2100 and is calculated by using $\Gamma = W_F/2L$.

* If the vapor density is significant, replace ρ^2 with $\rho_l(\rho_l - \rho_v)$.

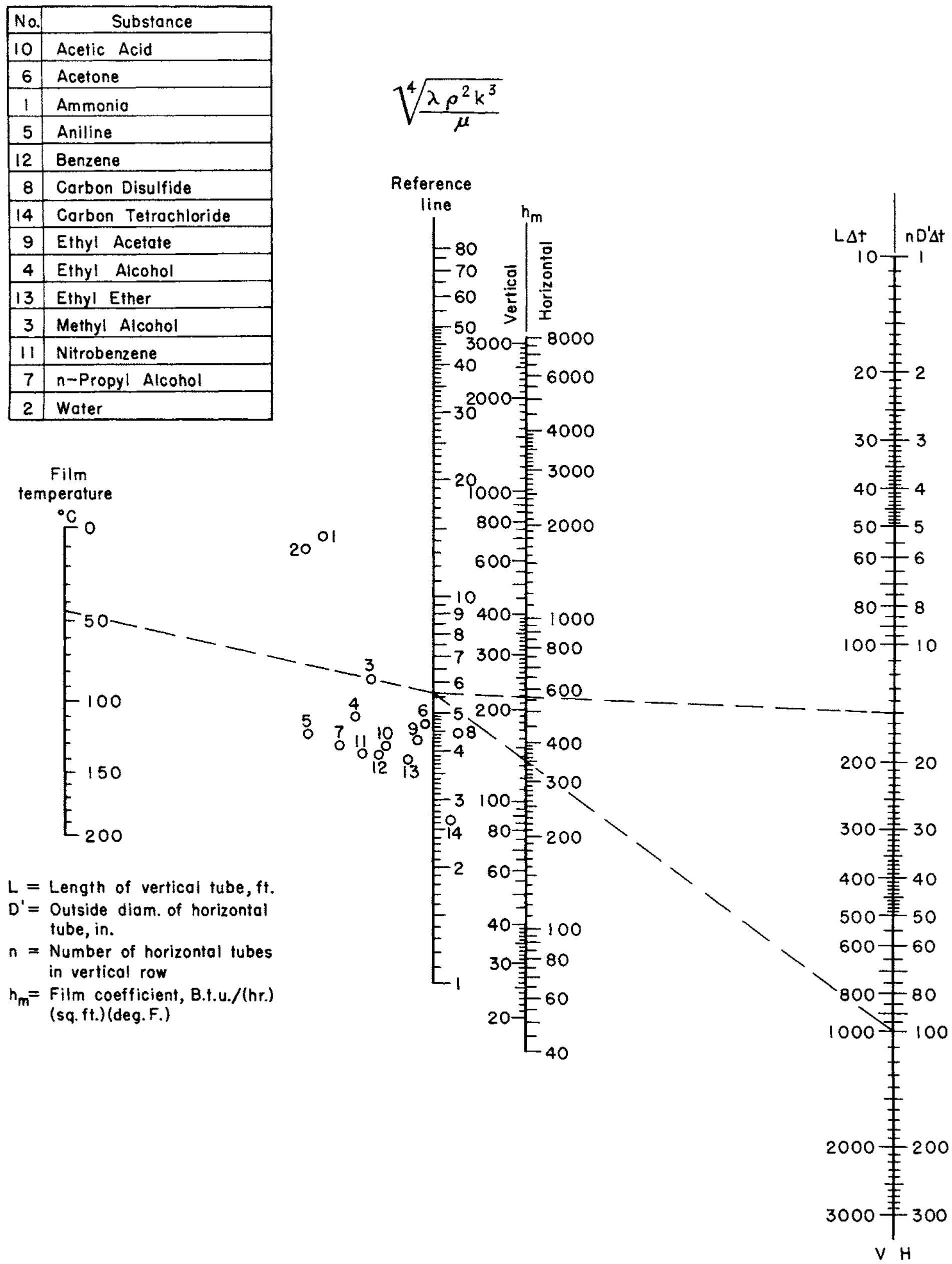

FIG. 5-7 Chart for determining heat-transfer coefficient h_m for film-type condensation of pure vapor, based on Eqs. (5-79) and (5-83). For vertical tubes multiply h_m by 1.2. If $4\Gamma/\mu_f$ exceeds 2100, use Fig. 5-8. $\sqrt[4]{\lambda\rho^2k^3/\mu}$ is in U.S. Customary units; to convert feet to meters, multiply by 0.3048; to convert inches to centimeters, multiply by 2.54; and to convert British thermal units per hour–square foot–degrees Fahrenheit to watts per square meter–kelvins, multiply by 5.6780.

Nusselt type:

$$\frac{hD}{k} = 0.73\left(\frac{D^3\rho^2 g\lambda}{k\mu\,\Delta t}\right)^{1/4} = 0.76\left(\frac{D^3\rho^2 g}{\mu\Gamma}\right)^{1/3} \qquad (5\text{-}83)^*$$

Dimensional:

$$h = b(k^3\rho^2L/\mu_bW_F)^{1/3} \qquad (5\text{-}84)^*$$

where b = 205.4 (SI) or 534 (U.S. Customary). For steam at atmospheric pressure

$$h = b(L/W_F)^{1/3} \qquad (5\text{-}85)$$

where b = 2080 (SI) or 4920 (U.S. Customary). For organic vapors at normal boiling point

$$h = b(L/W_F)^{1/3} \qquad (5\text{-}86)$$

where b = 324 (SI) or 766 (U.S. Customary).

Figure 5-7 is a nomograph for determining coefficients of heat transfer for condensation of pure vapors.

* If the vapor density is significant, replace ρ^2 with $\rho_l(\rho_l - \rho_v)$.

Banks of Horizontal Tubes (Re < 2100) In the idealized case of N tubes in a vertical row where the total condensate flows smoothly from one tube to the one beneath it, without splashing, and still in laminar flow on the tube, the mean condensing coefficient h_N for the entire row of N tubes is related to the condensing coefficient for the top tube h_1 by

$$h_N = h_1 N^{-1/4} \tag{5-87}$$

Dukler Theory The preceding expressions for condensation are based on the classical Nusselt theory. It is generally known and conceded that the film coefficients for steam and organic vapors calculated by the Nusselt theory are conservatively low. Dukler [*Chem. Eng. Prog.,* **55,** 62 (1959)] developed equations for velocity and temperature distribution in thin films on vertical walls based on expressions of Deissler (NACA Tech. Notes 2129, 1950; 2138, 1952; 3145, 1959) for the eddy viscosity and thermal conductivity near the solid boundary. According to the Dukler theory, three fixed factors must be known to establish the value of the average film coefficient: the terminal Reynolds number, the Prandtl number of the condensed phase, and a dimensionless group N_d defined as follows:

$$N_d = (0.250\mu_L^{1.173}\mu_G^{0.16})/(g^{2/3}D^2\rho_L^{0.553}\rho_G^{0.78}) \tag{5-88}$$

Graphical relationships of these variables are available in Document 6058, ADI Auxiliary Publications Project, Library of Congress, Washington. If rigorous values for condensing-film coefficients are desired, especially if the value of N_d in Eq. (5-88) exceeds $(1)(10^{-5})$, it is suggested that these graphs be used. For the case in which interfacial shear is zero, Fig. 5-8 may be used. It is interesting to note that, according to the Dukler development, there is no definite transition Reynolds number; deviation from Nusselt theory is less at low Reynolds numbers; and when the Prandtl number of a fluid is less than 0.4 (at Reynolds number above 1000), the predicted values for film coefficient are lower than those predicted by the Nusselt theory.

The Dukler theory is applicable for condensate films on horizontal tubes and also for falling films, in general, i.e., those not associated with condensation or vaporization processes.

Vapor Shear Controlling For **vertical in-tube condensation** with vapor and liquid flowing concurrently downward, if gravity controls, Figs. 5-7 and 5-8 may be used. If vapor shear controls, the Carpenter-Colburn correlation (*General Discussion on Heat Transfer,* London, 1951, ASME, New York, p. 20) is applicable:

$$h\mu_l/k_l\rho_l^{1/2} = 0.065(\text{Pr})_l^{1/2}F_{vc}^{1/2} \tag{5-89a}$$

where

$$F_{vc} = fG_{vm}^2/2\rho_v \tag{5-89b}$$

$$G_{vm} = \left(\frac{G_{vi}^2 + G_{vi}G_{vo} + G_{vo}^2}{3}\right)^{1/2} \tag{5-89c}$$

and f is the Fanning friction factor evaluated at

$$(\text{Re})_{vm} = D_iG_{vm}/\mu_v \tag{5-89d}$$

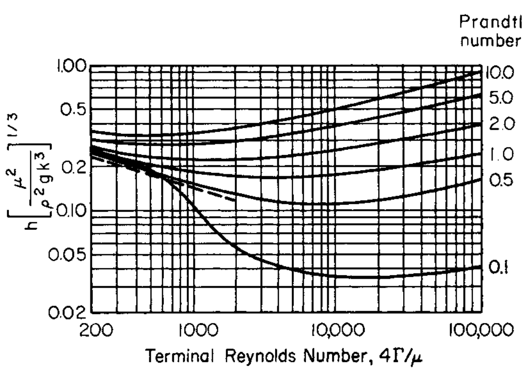

FIG. 5-8 Dukler plot showing average condensing-film coefficient as a function of physical properties of the condensate film and the terminal Reynolds number. (Dotted line indicates Nusselt theory for Reynolds number < 2100.) [*Reproduced by permission from* Chem. Eng. Prog., **55,** *64 (1959).*]

and the subscripts vi and vo refer to the vapor inlet and outlet, respectively. An alternative formulation, directly in terms of the friction factor, is

$$h = 0.065\ (c\rho kf/2\mu\rho_v)^{1/2}G_{vm} \tag{5-89e}$$

expressed in consistent units.

Another correlation for vapor-shear-controlled condensation is the Boyko-Kruzhilin correlation [*Int. J. Heat Mass Transfer,* **10,** 361 (1967)], which gives the mean condensing coefficient for a stream between inlet quality x_i and outlet quality x_o:

$$\frac{hD_i}{k_l} = 0.024\left(\frac{D_iG_T}{\mu_l}\right)^{0.8}(\text{Pr})_l^{0.43}\ \frac{\sqrt{(\rho/\rho_m)_i} + \sqrt{(\rho/\rho_m)_o}}{2} \tag{5-90a}$$

where G_T = total mass velocity in consistent units

$$\left(\frac{\rho}{\rho_m}\right)_i = 1 + \frac{\rho_l - \rho_v}{\rho_v}x_i \tag{5-90b}$$

and

$$\left(\frac{\rho}{\rho_m}\right)_o = 1 + \frac{\rho_l - \rho_v}{\rho_v}x_o \tag{5-90c}$$

For **horizontal in-tube condensation** at low flow rates Kern's modification (*Process Heat Transfer,* McGraw-Hill, New York, 1950) of the Nusselt equation is valid:

$$h_m = 0.761\left[\frac{Lk_l^3\rho_l(\rho_l - \rho_v)g}{W_F\mu_l}\right]^{1/3} = 0.815\left[\frac{k_l^3\rho_l(\rho_l - \rho_v)g\lambda}{\pi\mu_lD_i\ \Delta t}\right]^{1/4} \tag{5-91}$$

where W_F is the total vapor condensed in one tube and Δt is $t_{sv} - t_s$. A more rigorous correlation has been proposed by Chaddock [*Refrig. Eng.,* **65**(4), 36 (1957)]. Use consistent units.

At high condensing loads, with vapor shear dominating, tube orientation has no effect, and Eq. (5-90*a*) may also be used for horizontal tubes.

Condensation of pure vapors under laminar conditions in the presence of noncondensable gases, interfacial resistance, superheating, variable properties, and diffusion has been analyzed by Minkowycz and Sparrow [*Int. J. Heat Mass Transfer,* **9,** 1125 (1966)].

BOILING (VAPORIZATION) OF LIQUIDS

Boiling Mechanisms Vaporization of liquids may result from various mechanisms of heat transfer, singly or combinations thereof. For example, vaporization may occur as a result of heat absorbed, by radiation and convection, at the surface of a pool of liquid; or as a result of heat absorbed by natural convection from a hot wall beneath the disengaging surface, in which case the vaporization takes place when the superheated liquid reaches the pool surface. Vaporization also occurs from falling films (the reverse of condensation) or from the flashing of liquids superheated by forced convection under pressure.

Pool boiling refers to the type of boiling experienced when the heating surface is surrounded by a relatively large body of fluid which is not flowing at any appreciable velocity and is agitated only by the motion of the bubbles and by natural-convection currents. Two types of pool boiling are possible: subcooled pool boiling, in which the bulk fluid temperature is below the saturation temperature, resulting in collapse of the bubbles before they reach the surface, and saturated pool boiling, with bulk temperature equal to saturation temperature, resulting in net vapor generation.

The general shape of the curve relating the heat-transfer coefficient to Δt_b, the temperature driving force (difference between the wall temperature and the bulk fluid temperature) is one of the few parametric relations that are reasonably well understood. The familiar boiling curve was originally demonstrated experimentally by Nukiyama [*J. Soc. Mech. Eng.* (*Japan*), **37,** 367 (1934)]. This curve points out one of the great dilemmas for boiling-equipment designers. They are faced with at least six heat-transfer regimes in pool boiling: natural convection (+), incipient nucleate boiling (+), nucleate boiling (+), transition to film boiling (−), stable film boiling (+), and film boiling with increasing radiation (+). The signs indicate the sign of the derivative $d(q/A)/d\ \Delta t_b$. In the transition to film boiling, heat-transfer rate *decreases* with driving force. The regimes of greatest commercial interest are the *nucleate-boiling* and *stable-film-boiling regimes.*

Heat transfer by **nucleate boiling** is an important mechanism in the vaporization of liquids. It occurs in the vaporization of liquids in

kettle-type and natural-circulation reboilers commonly used in the process industries. High rates of heat transfer per unit of area (heat flux) are obtained as a result of bubble formation at the liquid-solid interface rather than from mechanical devices external to the heat exchanger. There are available several expressions from which reasonable values of the film coefficients may be obtained.

The boiling curve, particularly in the nucleate-boiling region, is significantly affected by the temperature driving force, the total system pressure, the nature of the boiling surface, the geometry of the system, and the properties of the boiling material. In the nucleate-boiling regime, heat flux is approximately proportional to the cube of the temperature driving force. Designers in addition must know the minimum Δt (the point at which nucleate boiling begins), the critical Δt (the Δt above which transition boiling begins), and the maximum heat flux (the heat flux corresponding to the critical Δt). For designers who do not have experimental data available, the following equations may be used.

Boiling Coefficients For the **nucleate-boiling coefficient** the Mostinski equation [*Teplenergetika,* **4,** 66 (1963)] may be used:

$$h = bP_c^{0.69}\left(\frac{q}{A}\right)^{0.7}\left[1.8\left(\frac{P}{P_c}\right)^{0.17} + 4\left(\frac{P}{P_c}\right)^{1.2} + 10\left(\frac{P}{P_c}\right)^{10}\right] \qquad (5\text{-}92)$$

where $b = (3.75)(10^{-5})$(SI) or $(2.13)(10^{-4})$ (U.S. Customary), P_c is the critical pressure and P the system pressure, q/A is the heat flux, and h is the nucleate-boiling coefficient. The McNelly equation [*J. Imp. Coll. Chem. Eng. Soc.*, 7(18), (1953)] may also be used:

$$h = 0.225\left(\frac{qc_l}{A\lambda}\right)^{0.69}\left(\frac{Pk_l}{\sigma}\right)^{0.31}\left(\frac{\rho_l}{\rho_v} - 1\right)^{0.33} \qquad (5\text{-}93)$$

where c_l is the liquid heat capacity, λ is the latent heat, P is the system pressure, k_l is the thermal conductivity of the liquid, and σ is the surface tension.

An equation of the Nusselt type has been suggested by Rohsenow [*Trans. Am. Soc. Mech. Eng.,* **74,** 969 (1952)].

$$hD/k = C_r(DG/\mu)^{2/3}(c\mu/k)^{-0.7} \qquad (5\text{-}94a)$$

in which the variables assume the following form:

$$\frac{h\beta'}{k}\left[\frac{g_c\sigma}{g(\rho_L - \rho_v)}\right]^{1/2} = C_r\left[\frac{\beta'}{\mu}\left(\frac{g_c\sigma}{g(\rho_L - \rho_v)}\right)^{1/2}\frac{W}{A}\right]^{2/3}\left(\frac{c\mu}{k}\right)^{-0.7} \qquad (5\text{-}94b)$$

The coefficient C_r is not truly constant but varies from 0.006 to 0.015.* It is possible that the nature of the surface is partly responsible for the variation in the constant. The only factor in Eq. (5-94*b*) not readily available is the value of the contact angle β'.

Another Nusselt-type equation has been proposed by Forster and Zuber:†

$$\text{Nu} = 0.0015\ \text{Re}^{0.62}\ \text{Pr}^{1/3} \qquad (5\text{-}95)$$

which takes the following form:

$$\frac{c\rho_L\sqrt{\pi\alpha}}{k\rho_v}\frac{W}{A}\left(\frac{2\sigma}{\Delta p}\right)^{1/2}\left(\frac{\rho_L}{\Delta p g_c}\right)^{1/4} = 0.0015\left[\frac{\rho_L}{\mu}\left(\frac{c\rho_L\,\Delta T\sqrt{\pi\alpha}}{\lambda\rho_v}\right)^2\right]^{0.62}\left(\frac{c\mu}{k}\right)^{1/2} \qquad (5\text{-}96)$$

where $\alpha = k/\rho c$ (all liquid properties)

Δp = pressure of the vapor in a bubble minus saturation pressure of a flat liquid surface

Equations (5-94*b*) and (5-96) have been arranged in dimensional form by Westwater.

The numerical constant may be adjusted to suit any particular set of data if one desires to use a certain criterion. However, surface conditions vary so greatly that deviations may be as large as ±25 percent from results obtained.

The **maximum heat flux** may be predicted by the Kutateladse-Zuber [*Trans. Am. Soc. Mech. Eng.,* **80,** 711 (1958)] relationship, using consistent units:

$$\left(\frac{q}{A}\right)_{\max} = 0.18g_c^{1/4}\rho_v\lambda\left[\frac{(\rho_l - \rho_v)\sigma g}{\rho_v^2}\right]^{1/4} \qquad (5\text{-}97)$$

Alternatively, Mostinski presented an equation which approximately represents the Cichelli-Bonilla [*Trans. Am. Inst. Chem. Eng.,* **41,** 755 (1945)] correlation:

$$\frac{(q/A)_{\max}}{P_c} = b\left(\frac{P}{P_c}\right)^{0.35}\left(1 - \frac{P}{P_c}\right)^{0.9} \qquad (5\text{-}98)$$

where $b = 0.368$(SI) or 5.58 (U.S. Customary); P_c is the critical pressure, Pa absolute; P is the system pressure; and $(q/A)_{\max}$ is the maximum heat flux.

The lower limit of applicability of the nucleate-boiling equations is from 0.1 to 0.2 of the maximum limit and depends upon the magnitude of natural-convection heat transfer for the liquid. The best method of determining the lower limit is to plot two curves: one of h versus Δt for natural convection, the other of h versus Δt for nucleate boiling. The intersection of these two curves may be considered the lower limit of applicability of the equations.

These equations apply to single tubes or to flat surfaces in a large pool. In tube bundles the equations are only approximate, and designers must rely upon experiment. Palen and Small [*Hydrocarbon Process.,* **43**(11), 199 (1964)] have shown the effect of tube-bundle size on maximum heat flux.

$$\left(\frac{q}{A}\right)_{\max} = b\,\frac{p}{D_o\sqrt{N_T}}\,\rho_v\lambda\left[\frac{g\sigma(\rho_l - \rho_v)}{\rho_v^2}\right]^{1/4} \qquad (5\text{-}99)$$

where $b = 0.43$ (SC) or 61.6 (U.S. Customary), p is the tube pitch, D_o is the tube outside diameter, and N_T is the number of tubes (twice the number of complete tubes for U-tube bundles).

For **film boiling,** Bromley's [*Chem. Eng. Prog.,* **46,** 221 (1950)] correlation may be used:

$$h = b\left[\frac{k_v^3(\rho_l - \rho_v)\rho_v g}{\mu_v D_o\,\Delta t_b}\right]^{1/4} \qquad (5\text{-}100)$$

where $b = 4.306$ (SI) or 0.620 (U.S. Customary). Katz, Myers, and Balekjian [*Pet. Refiner,* **34**(2), 113 (1955)] report boiling heat-transfer coefficients on finned tubes.

INTRODUCTION

Heat transfer by thermal radiation involves the transport of electromagnetic (EM) energy from a source to a sink. In contrast to other modes of heat transfer, radiation does not require the presence of an intervening medium, e.g., as in the irradiation of the earth by the sun. Most industrially important applications of radiative heat transfer occur in the *near infrared* portion of the EM spectrum (0.7 through 25 μm) and may extend into the *far infrared* region (25 to 1000 μm). For very high temperature sources, such as solar radiation, relevant wavelengths encompass the entire *visible region* (0.4 to 0.7 μm) and may extend down to 0.2 μm in the *ultraviolet* (0.01- to 0.4-μm) portion of the EM spectrum. Radiative transfer can also exhibit unique *action-at-a-distance* phenomena which do not occur in other modes of heat transfer. Radiation differs from conduction and convection not only with regard to mathematical characterization but also with regard to its fourth power dependence on temperature. Thus it is usually dominant in high-temperature combustion applications. The temperature at which radiative transfer accounts for roughly one-half of the total heat loss from a surface in air depends on such factors as surface **emissivity** and the convection coefficient. For pipes in free convection, radiation is important at ambient temperatures. For fine wires of low emissivity it becomes important at temperatures associated with bright red heat (1300 K). Combustion gases at furnace temperatures typically lose more than 90 percent of their energy by radiative emission from constituent carbon dioxide, water vapor, and particulate matter. Radiative transfer methodologies are important in myriad engineering applications. These include semiconductor processing, illumination theory, and gas turbines and rocket nozzles, as well as furnace design.

THERMAL RADIATION FUNDAMENTALS

In a vacuum, the wavelength λ, frequency, ν and wavenumber η for electromagnetic radiation are interrelated by $\lambda = c/\nu = 1/\eta$, where c is the speed of light. Frequency is independent of the index of refraction of a medium n, but both the speed of light and the wavelength in the medium vary according to $c_m = c/n$ and $\lambda_m = \lambda/n$. When a radiation beam passes into a medium of different refractive index, not only does its wavelength change but so does its direction (Snell's law) as well as the magnitude of its intensity. In most engineering heat-transfer calculations, wavelength is usually employed to characterize radiation while wave number is often used in gas spectroscopy. For a vacuum, air at ambient conditions, and most gases, $n \approx 1.0$. For this reason this presentation sometimes does not distinguish between λ and λ_m. *Dielectric materials* exhibit $1.4 < n < 4$, and the speed of light decreases considerably in such media.

In radiation heat transfer, the **monochromatic intensity** $I_\lambda \equiv I_\lambda(\vec{\mathbf{r}}, \vec{\boldsymbol{\Omega}}, \lambda)$, is a *fundamental* (scalar) *field variable* which characterizes EM energy transport. Intensity defines the radiant energy flux passing through an infinitesimal area dA, oriented *normal* to a radiation beam of arbitrary direction $\vec{\boldsymbol{\Omega}}$. At steady state, the monochromatic intensity is a function of position $\vec{\mathbf{r}}$, direction $\vec{\boldsymbol{\Omega}}$, and wavelength and has units of W/(m^2·sr·μm). In the general case of an *absorbing-emitting* and *scattering* medium, characterized by some absorption coefficient K(m^{-1}), intensity in the direction $\vec{\boldsymbol{\Omega}}$ will be modified by attenuation and by *scattering* of radiation into and out of the beam. For the special case of a nonabsorbing (transparent), nonscattering, medium of constant refractive index, the radiation intensity *is constant and independent of position in a given direction* $\vec{\boldsymbol{\Omega}}$. This circumstance arises in *illumination theory* where the light intensity in a room is constant in a *given direction* but may vary with respect to *all other directions*. The basic conservation law for radiation intensity is termed the *equation of transfer* or *radiative transfer equation*. The equation of transfer is a *directional* energy balance and mathematically is an *integrodifferential equation*. The relevance of the transport equation to radiation heat transfer is discussed in many sources; see, e.g., Modest, M. F., *Radiative Heat Transfer*, 2d ed., Academic Press, 2003, or Siegel, R., and J. R. Howell, *Thermal Radiative Heat Transfer*, 4th ed., Taylor & Francis, New York, 2001.

Introduction to Radiation Geometry Consider a homogeneous medium of constant refractive index n. A pencil of radiation originates at differential area element dA_i and is incident on differential area element dA_j. Designate $\vec{\mathbf{n}}_i$ and $\vec{\mathbf{n}}_j$ as the unit vectors normal to dA_i and dA_j, and let r, with unit direction vector $\vec{\boldsymbol{\Omega}}$, define the distance of separation between the area elements. Moreover, ϕ_i and ϕ_j denote the *confined angles* between $\vec{\boldsymbol{\Omega}}$ and $\vec{\mathbf{n}}_i$ and $\vec{\mathbf{n}}_j$, respectively [i.e., $\cos\phi_i \equiv \cos(\vec{\boldsymbol{\Omega}}, \vec{\mathbf{r}}_i)$ and $\cos\phi_j \equiv \cos(\vec{\boldsymbol{\Omega}}, \vec{\mathbf{r}}_j)$]. As the beam travels toward dA_j, it will *diverge* and subtend a solid angle

$$d\Omega_j = \frac{\cos\phi_j}{r^2}\, dA_j \text{ sr}$$

at dA_i. Moreover, the projected area of dA_i in the direction of $\vec{\boldsymbol{\Omega}}$ is given by $\cos(\vec{\boldsymbol{\Omega}}, \vec{\mathbf{r}}_i)\, dA_i = \cos\phi_i\, dA_i$. Multiplication of the intensity $I_\lambda \equiv I_\lambda(\vec{\mathbf{r}}, \vec{\boldsymbol{\Omega}}, \lambda)$ by $d\Omega_j$ and the apparent area of dA_i then yields an expression for the (*differential*) net *monochromatic radiant energy flux* $dQ_{i,j}$ originating at dA_i and intercepted by dA_j.

$$dQ_{i,j} \equiv I_\lambda(\vec{\boldsymbol{\Omega}}, \lambda) \cos\phi_i \cos\phi_j\, dA_i\, dA_j/r^2 \tag{5-101}$$

The **hemispherical emissive power*** E is defined as the radiant flux density (W/m^2) associated with emission from an element of surface area dA into a surrounding unit hemisphere whose base is coplanar with dA. If the monochromatic intensity $I_\lambda(\vec{\boldsymbol{\Omega}}, \lambda)$ of emission from the surface is *isotropic* (independent of the angle of emission, $\vec{\boldsymbol{\Omega}}$), Eq. (5-101) may be integrated over the 2π sr of the surrounding unit hemisphere to yield the simple relation $E_\lambda = \pi I_\lambda$, where $E_\lambda \equiv E_\lambda(\lambda)$ is defined as the monochromatic or *spectral* hemispherical emissive power.

Blackbody Radiation Engineering calculations involving thermal radiation normally employ the **hemispherical blackbody emissive power** as the thermal driving force analogous to temperature in the cases of conduction and convection. A **blackbody** is a theoretical idealization for a *perfect theoretical radiator*; i.e., it absorbs all incident radiation without reflection and emits isotropically. In practice, soot-covered surfaces sometimes approximate blackbody behavior. Let $E_{b,\lambda} = E_{b,\lambda}(T,\lambda)$ denote the monochromatic blackbody hemispherical emissive power *frequency function* defined such that $E_{b,\lambda}(T, \lambda)d\lambda$ represents the fraction of blackbody energy lying in the wavelength region from λ to $\lambda + d\lambda$. The function $E_{b,\lambda} = E_{b,\lambda}(T,\lambda)$ is given by **Planck's law**

$$\frac{E_{b,\lambda}(T,\lambda)}{n^2T^5} = \frac{c_1(\lambda T)^{-5}}{e^{c_2/\lambda T} - 1} \tag{5-102}$$

where $c_1 = 2\pi hc^2$ and $c_2 = hc/k$ are defined as Planck's first and second constants, respectively.

Integration of Eq. (5-102) over all wavelengths yields the **Stefan-Boltzman law** for the hemispherical blackbody emissive power

$$E_b(T) = \int_{\lambda=0}^{\infty} E_{b,\lambda}(T, \lambda)\, d\lambda = n^2\sigma T^4 \tag{5-103}$$

where $\sigma = c_1(\pi/c_2)^4/15$ is the Stephan-Boltzman constant. Since a blackbody is an *isotropic emitter*, it follows that the intensity of blackbody emission is given by the simple formula $I_b = E_b/\pi = n^2\sigma T^4/\pi$. The intensity of radiation emitted over all wavelengths by a blackbody is thus uniquely determined by its temperature. In this presentation, all references to hemispherical emissive power shall be to the *blackbody* emissive power, and the subscript b may be suppressed for expediency.

For short wavelengths $\lambda T \to 0$, the asymptotic form of Eq. (5-102) is known as the **Wien equation**

$$\frac{E_{b,\lambda}(T, \lambda)}{n^2T^5} \cong c_1(\lambda T)^{-5} e^{-c_2/\lambda T} \tag{5-104}$$

The error introduced by use of the Wien equation is less than 1 percent when $\lambda T < 3000$ μm·K. The Wien equation has significant practical value in optical pyrometry for $T < 4600$ K when a red filter ($\lambda = 0.65$ μm) is employed. The long-wavelength asymptotic approximation for Eq. (5-102) is known as the **Rayleigh-Jeans formula,** which is accurate to within 1 percent for $\lambda T > 778{,}000$ μm·K. The Raleigh-Jeans formula is of limited engineering utility since a blackbody emits over 99.9 percent of its total energy below the value of $\lambda T = 53{,}000$ μm·K.

*In the literature the emissive power is variously called the emittance, total hemispherical intensity, or radiant flux density.

Nomenclature and Units—Radiative Transfer

Symbol	Definition
$a, a_g, a_{g,1}$	WSGG spectral model clear plus gray weighting constants
$\overline{C}_p$, $\overline{C}_{P,Prod}$	Heat capacity per unit mass, $J \cdot kg^{-1} \cdot K^{-1}$
$ij = \overline{s_i s_j}$	Shorthand notation for direct exchange area
A, A_i	Area of enclosure or zone i, m^2
c	Speed of light in vacuum, m/s
c_1, c_2	Planck's first and second constants, $W \cdot m^2$ and $m \cdot K$
d_p, r_p	Particle diameter and radius, μm
$E_{b,\lambda} = E_{b,\lambda}(T,\lambda)$	Monochromatic, blackbody emissive power, $W/(m^2 \cdot \mu m)$
$E_n(x)$	Exponential integral of order n, where $n = 1, 2, 3, \ldots$
E	Hemispherical emissive power, W/m^2
$E_b = n^2 \sigma T^4$	Hemispherical blackbody emissive power, W/m^2
f_v	Volumetric fraction of soot
$F_b(\lambda T)$	Blackbody fractional energy distribution
F_{ij}	Direct view factor from surface zone i to surface zone j
$\overline{F}_{i,j}$	Refractory augmented black view factor; F-bar
$\mathcal{F}_{i,j}$	Total view factor from surface zone i to surface zone j
h	Planck's constant, J·s
h_i	Heat-transfer coefficient, $W/(m^2 \cdot K)$
H_i	Incident flux density for surface zone i, W/m^2
H	Enthalpy rate, W
$\dot{H}_F$	Enthalpy feed rate, W
$I_\lambda \equiv I_\lambda(\vec{\mathbf{r}}, \vec{\mathbf{\Omega}}, \lambda)$	Monochromatic radiation intensity, $W/(m^2 \cdot \mu m \cdot sr)$
k	Boltzmann's constant, J/K
$k_{\lambda,p}$	Monochromatic line absorption coefficient, $(atm \cdot m)^{-1}$
K	Gas absorption coefficient, m^{-1}
L_M, L_{M0}	Average and optically thin mean beam lengths, m
$\dot{m}$	Mass flow rate, kg/h^{-1}
n	Index of refraction
M, N	Number of surface and volume zones in enclosure
p_k	Partial pressure of species k, atm
P	Number of WSGG gray gas spectral windows
Q_i	Total radiative flux originating at surface zone i, W
$Q_{i,j}$	Net radiative flux between zone i and zone j, W
T	Temperature, K
U	Overall heat-transfer coefficient in WSCC model
V	Enclosure volume, m^3
W	Leaving flux density (radiosity), W/m^2

Greek Characters

Symbol	Definition
α, $\alpha_{1,2}$	Surface absorptivity or absorptance; subscript 1 refers to the surface temperature while subscript 2 refers to the radiation source
$\alpha_{g,1}$, ε_g, $\tau_{g,1}$	Gas absorptivity, emissivity, and transmissivity
β	Dimensionless constant in mean beam length equation, $L_M = \beta \cdot L_{M0}$
$\Delta T_{ge} \equiv T_g - T_e$	Adjustable temperature fitting parameter for WSCC model, K
ε	Gray diffuse surface emissivity
$\varepsilon_g(T, r)$	Gas emissivity with path length r
$\varepsilon_\lambda(T, \Omega, \lambda)$	Monochromatic, unidirectional, surface emissivity
$\eta = 1/\lambda$	Wave number in vacuum, cm^{-1}
$\lambda = c/\nu$	Wavelength in vacuum, μm
ν	Frequency, Hz
$\rho = 1 - \varepsilon$	Diffuse reflectivity
σ	Stefan-Boltzmann constant, $W/(m^2 \cdot K^4)$
Σ	Number of unique direct surface-to-surface direct exchange areas
$\tau_g = 1 - \varepsilon_g$	Gas transmissivity
Ω	Solid angle, sr (steradians)
Φ	Equivalence ratio of fuel and oxidant
$\Psi^{(3)}(x)$	Pentagamma function of x
ω	Albedo for single scatter

Dimensionless Quantities

Symbol	Definition
$D_{\text{eff}} = \dfrac{N_{FD}}{(\overline{S_1 G_R}/A_1) + N_{CR}}$	Effective firing density
$N_{CR} = \dfrac{h}{4\sigma T_{g,1}^3}$	Convection-radiation number
$N_{FD} = \dot{H}_f/\sigma T_{\text{Ref}}^4 \cdot A_1$	Dimensionless firing density
η_g	Gas-side furnace efficiency
$\eta'_g = \eta_g(1 - \Theta_0)$	Reduced furnace efficiency
$\Theta_i = T_i/T_{\text{Ref}}$	Dimensionless temperature

Vector Notation

Symbol	Definition
$\vec{\mathbf{n}}_i$ and $\vec{\mathbf{n}}_j$	Unit vectors normal to differential area elements dA_i and dA_j
$\vec{\mathbf{r}}$	Position vector
$\vec{\mathbf{\Omega}}$	Arbitrary unit direction vector

Matrix Notation

Symbol	Definition
$\mathbf{1}_M$	Column vector; all of whose elements are unity. $[M \times 1]$
$\mathbf{I} = [\delta_{i,j}]$	Identity matrix, where $\delta_{i,j}$ is the Kronecker delta; i.e., $\delta_{i,j} = 1$ for $i = j$ and $\delta_{i,j} = 0$ for $i \neq j$.
$\mathbf{aI}$	Diagonal matrix of WSGG gray gas surface zone a-weighting factors $[M \times M]$
$\mathbf{a}_g\mathbf{I}$	Diagonal matrix of gray gas WSGG volume zone a-weighting factors $[N \times N]$
$\mathbf{A} = [A_{i,j}]$	Arbitrary nonsingular square matrix
$\mathbf{A}^T = [A_{j,i}]$	Transpose of $\mathbf{A}$
$\mathbf{A}^{-1} = [A_{i,j}]^{-1}$	Inverse of $\mathbf{A}$
$\mathbf{DI} = [D_i \cdot \delta_{i,j}]$	Arbitrary diagonal matrix
$\mathbf{DI}^{-1} = [\delta_{i,j}/D_i]$	Inverse of diagonal matrix
$\mathbf{CDI}$	$\mathbf{CI} \cdot \mathbf{DI} = [C_i \cdot D_i \cdot \delta_{i,j}]$, product of two diagonal matrices
$\mathbf{AI} = [A_i \cdot \delta_{i,j}]$	Diagonal matrix of surface zone areas, m^2 $[M \times M]$
$\boldsymbol{\varepsilon}\mathbf{I} = [\varepsilon_i \cdot \delta_{i,j}]$	Diagonal matrix of diffuse zone emissivities $[M \times M]$
$\boldsymbol{\rho}\mathbf{I} = [\rho_i \cdot \delta_{i,j}]$	Diagonal matrix of diffuse zone reflectivities $[M \times M]$
$\mathbf{E} = [E_i] = [\sigma T_i^4]$	Column vector of surface blackbody hemispherical emissive powers, W/m^2 $[M \times 1]$
$\mathbf{EI} = [E_i \cdot \delta_{i,j}] = [\sigma T_i^4 \cdot \delta_{i,j}]$	Diagonal matrix of surface blackbody emissive powers, W/m^2 $[M \times M]$
$\mathbf{E}_g = [E_{g,i}] = [\sigma T_{g,i}^4]$	Column vector of gas blackbody hemispherical emissive powers, W/m^2 $[N \times 1]$
$\mathbf{E_g I} = [E_i \cdot \delta_{i,j}] = [\sigma T_i^4 \cdot \delta_{i,j}]$	Diagonal matrix of gas blackbody emissive powers, W/m^2 $[N \times N]$
$\mathbf{H} = [H_i]$	Column vector of surface zone incident flux densities, W/m^2 $[M \times 1]$
$\mathbf{W} = [W_i]$	Column vector of surface zone leaving flux densities, W/m^2 $[M \times 1]$
$\mathbf{Q} = [Q_i]$	Column vector of surface zone fluxes, W $[M \times 1]$
$\mathbf{R} = [\mathbf{AI} - \overline{\mathbf{ss}} \cdot \boldsymbol{\rho}\mathbf{I}]^{-1}$	Inverse multiple-reflection matrix, m^{-2} $[M \times M]$
$\mathbf{KI_p} = [\delta_{i,j} \cdot K_{p,i}]$	Diagonal matrix of WSGG $K_{p,i}$ values for the ith zone and pth gray gas component, m^{-1} $[N \times N]$
$\overleftarrow{\mathbf{KI}}$	Diagonal matrix of WSGG-weighted gray gas absorption coefficients, m^{-1} $[N \times N]$
$\mathbf{S'}$	Column vector for net volume absorption, W $[N \times 1]$
$\overline{\mathbf{ss}} = [\overline{s_i s_j}]$	Array of direct surface-to-surface exchange areas, m^2 $[M \times M]$
$\overline{\mathbf{sg}} = [\overline{s_i g_j}] = \overline{\mathbf{gs}}^T$	Array of direct gas-to-surface exchange areas, m^2 $[M \times N]$
$\overline{\mathbf{gg}} = [\overline{g_i g_j}]$	Array of direct gas-to-gas exchange areas, m^2 $[N \times N]$
$\overline{\mathbf{SS}} = [\overline{S_i S_j}]$	Array of total surface-to-surface exchange areas, m^2 $[M \times M]$
$\overline{\mathbf{SG}} = [\overline{S_i G_j}]$	Array of total gas-to-surface exchange areas, m^2 $[M \times N]$
$\overline{\mathbf{GS}} = \overline{\mathbf{GS}}^T$	Array of total surface-to-gas exchange areas, m^2 $[N \times M]$
$\overline{\mathbf{GG}} = [\overline{G_i G_j}]$	Array of total gas-to-gas exchange areas, m^2 $[N \times N]$
$\overleftarrow{\mathbf{SS}} = [\overleftarrow{S_i S_i}]$	Array of directed surface-to-surface exchange areas, m^2 $[M \times M]$
$\overleftarrow{\mathbf{SG}} = [\overleftarrow{S_i G_i}]$	Array of directed gas-to-surface exchange areas, m^2 $[M \times N]$
$\overleftarrow{\mathbf{GS}} \neq \overleftarrow{\mathbf{SG}}^T$	Array of directed surface-to-gas exchange areas, m^2 $[N \times M]$
$\overleftarrow{\mathbf{GG}} = [\overleftarrow{G_i G_i}]$	Array of directed gas-to-gas exchange areas, m^2 $[N \times N]$
$\mathbf{VI} = [V_i \cdot \delta_{i,j}]$	Diagonal matrix of zone volumes, m^3 $[N \times N]$

Subscripts

Symbol	Definition
b	Blackbody or denotes a black surface zone
f	Denotes flux surface zone
h	Denotes hemispherical surface emissivity
i, j	Zone number indices
n	Denotes normal component of surface emissivity
p	Index for pth gray gas window
r	Denotes refractory surface zone
s	Denotes source-sink surface zone
λ	Denotes monochromatic variable
Ref	Denotes reference quantity

Abbreviations

Abbreviation	Definition
CFD	Computational fluid dynamics
DO, FV	Discrete ordinate and finite volume methods
EM	Electromagnetic
RTE	Radiative transfer equation; equation of transfer
LPFF	Long plug flow furnace model
SSR	Source-sink refractory model
WSCC	Well-stirred combustion chamber model
WSGG	Weighted sum of gray gases spectral model

The blackbody fractional energy *distribution function* is defined by

$$F_b(\lambda T) = \frac{\int_{\lambda=0}^{\lambda} E_{b,\lambda}(T, \lambda)\, d\lambda}{\int_{\lambda=0}^{\infty} E_{b,\lambda}(T, \lambda)\, d\lambda} \tag{5-105}$$

The function $F_b(\lambda T)$ defines the fraction of total energy in the blackbody spectrum which lies below λT and is a unique function of λT. For purposes of digital computation, the following series expansion for $F_b(\lambda T)$ proves especially useful.

$$F_b(\lambda T) = \frac{15}{\pi^4} \sum_{k=1}^{\infty} \frac{e^{-k\xi}}{k} \left(\xi^3 + \frac{3\xi^2}{k} + \frac{6\xi}{k^2} + \frac{6}{k^3} \right) \quad \text{where } \xi = \frac{c_2}{\lambda T} \tag{5-106}$$

Equation (5-106) converges rapidly and is due to Lowan [1941] as referenced in Chang and Rhee [*Int. Comm. Heat Mass Transfer*, **11,** 451–455 (1984)].

Numerically, in the preceding, $h = 6.6260693 \times 10^{-34}$ J·s is the Planck constant; $c = 2.99792458 \times 10^8$ m/s is the velocity of light in vacuum; and $k = 1.3806505 \times 10^{-23}$ J/K is the Boltzmann constant. These data lead to the following values of Planck's first and second constants: $c_1 = 3.741771 \times 10^{-16}$ W·m² and $c_2 = 1.438775 \times 10^{-2}$ m·K, respectively. Numerical values of the Stephan-Boltzmann constant σ in several systems of units are as follows: 5.67040×10^{-8} W/(m²·K⁴); 1.3544×10^{-12} cal/(cm²·s·K⁴); 4.8757×10^{-8} kcal/(m²·h·K⁴); 9.9862×10^{-9} CHU/(ft²·h·K⁴); and 0.17123×10^{-8} Btu/(ft²·h·°R⁴) (CHU = centigrade heat unit; 1.0 CHU = 1.8 Btu.)

Blackbody Displacement Laws The blackbody energy spectrum is plotted *logarithmically* in Fig. 5-9 as $\frac{E_{b,\lambda}(\lambda T)}{n^2 T^5} \times 10^{13} \frac{\text{W}}{\text{m}^2\cdot\mu\text{m}\cdot\text{K}^5}$ versus λT μm·K. For comparison a companion inset is provided in Cartesian coordinates. The upper abscissa of Fig. 5-9 also shows the blackbody energy distribution function $F_b(\lambda T)$. Figure 5-9 indicates that the wavelength-temperature product for which the maximum intensity occurs is $\lambda_{max}T = 2898$ μm·K. This relationship is known as **Wien's displacement law,** which indicates that the wavelength for maximum intensity is *inversely* proportional to the absolute temperature. Blackbody displacement laws are useful in engineering practice to estimate wavelength intervals appropriate to relevant system temperatures. The Wien displacement law can be misleading, however, because the wavelength for maximum intensity depends on whether the intensity is defined in terms of frequency or wavelength interval. Two additional useful displacement laws are defined in terms of either the value of λT corresponding to the maximum energy per unit *fractional change* in wavelength or frequency, that is, $\lambda T = 3670$ μm·K, or to the value of λT corresponding to one-half the blackbody energy, that is, $\lambda T = 4107$ μm·K. Approximately one-half of the blackbody energy lies within the twofold λT range *geometrically centered* on $\lambda T = 3670$ μm·K, that is, $3670/\sqrt{2} < \lambda T < 3670\sqrt{2}$ μm·K. Some 95 percent of the blackbody energy lies in the interval $1662.6 < \lambda T < 16{,}295$ μm·K. It thus follows that for the temperature range between ambient (300 K) and flame temperatures (2000 K or

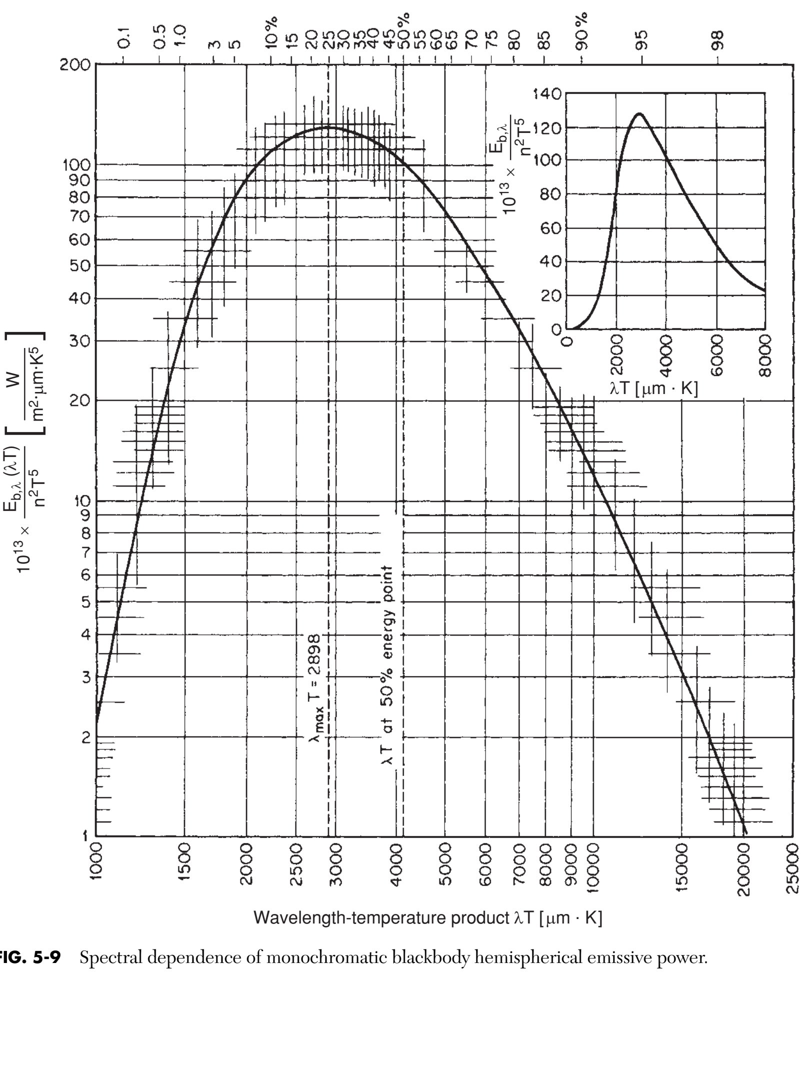

FIG. 5-9 Spectral dependence of monochromatic blackbody hemispherical emissive power.

3140°F), wavelengths of engineering heat-transfer importance are *bounded* between 0.83 and 54.3 μm.

RADIATIVE PROPERTIES OF OPAQUE SURFACES

Emittance and Absorptance The ratio of the total radiating power of any surface to that of a black surface at the same temperature is called the **emittance** or **emissivity,** ε of the surface.* In general, the monochromatic emissivity is a function of temperature, direction, and wavelength, that is, $\varepsilon_\lambda = \varepsilon_\lambda(T, \vec{\Omega}, \lambda)$. The subscripts n and h are sometimes used to denote the normal and hemispherical values, respectively, of the emittance or emissivity. If radiation is incident on a surface, the fraction absorbed is called the **absorptance** (**absorptivity**). Two subscripts are usually appended to the absorptance $\alpha_{1,2}$ to distinguish between the temperature of the absorbing surface T_1 and the spectral energy distribution of the emitting surface T_2. According to **Kirchhoff's law,** the emissivity and absorptivity of a surface exposed to surroundings at its own temperature are the same for both monochromatic and total radiation. When the temperatures of the surface and its surroundings differ, the total emissivity and absorptivity of the surface are often found to be unequal; but because the absorptivity is substantially independent of irradiation density, the monochromatic emissivity and absorptivity of surfaces are equal for all practical purposes. The difference between *total* emissivity and absorptivity depends on the variation of ε_λ with wavelength and on the difference between the temperature of the surface and the effective temperature of the surroundings.

Consider radiative exchange between a real surface of area A_1 at temperature T_1 with black surroundings at temperature T_2. The *net* radiant interchange is given by

$$Q_{1,2} = A_1 \int_{\lambda=0}^{\infty} [\varepsilon_\lambda(T_1, \lambda) \cdot E_{b,\lambda}(T_1,\lambda) - \alpha_\lambda(T_1,\lambda) \cdot E_{b,\lambda}(T_2,\lambda)]\, d\lambda \qquad (5\text{-}107a)$$

or

$$Q_{1,2} = A_1(\varepsilon_1 \sigma T_1^4 - \alpha_{1,2}\sigma T_2^4) \qquad (5\text{-}107b)$$

where

$$\varepsilon_1(T_1) = \int_{\lambda=0}^{\infty} \varepsilon_\lambda(T_1,\lambda) \cdot \frac{E_{b,\lambda}(T_1,\lambda)}{E_b(T_1)}\, d\lambda \qquad (5\text{-}108)$$

and since $\alpha_\lambda(T,\lambda) = \varepsilon_\lambda(T,\lambda)$,

$$\alpha_{1,2}(T_1,T_2) = \int_{\lambda=0}^{\infty} \varepsilon_\lambda(T_1,\lambda) \cdot \frac{E_{b,\lambda}(T_2,\lambda)}{E_b(T_2)}\, d\lambda \qquad (5\text{-}109)$$

For a *gray surface* $\varepsilon_1 = \alpha_{1,2} = \varepsilon_\lambda$. A *selective surface* is one for which $\varepsilon_\lambda(T,\lambda)$ exhibits a strong dependence on wavelength. If the wavelength dependence is *monotonic*, it follows from Eqs. (5-107) to (5-109) that ε_1 and $\alpha_{1,2}$ can differ markedly when T_1 and T_2 are widely separated. For example, in solar energy applications, the nominal temperature of the earth is T_1 = 294 K, and the sun may be represented as a blackbody with radiation temperature T_2 = 5800 K. For these temperature conditions, a *white paint* can exhibit $\varepsilon_1 = 0.9$ and $\alpha_{1,2}$ = 0.1 to 0.2. In contrast, a *thin layer of copper oxide on bright aluminum* can exhibit ε_1 as low as 0.12 and $\alpha_{1,2}$ greater than 0.9.

The effect of radiation source temperature on low-temperature absorptivity for a number of representative materials is shown in Fig. 5-10. Polished aluminum (curve 15) and anodized (surface-oxidized) aluminum (curve 13) are representative of metals and nonmetals, respectively. Figure 5-10 thus demonstrates the generalization that metals and nonmetals respond *in opposite directions* with regard to changes in the radiation source temperature. Since the effective solar temperature is 5800 K (10,440°R), the extreme right-hand side of Fig. 5-10 provides surface absorptivity data relevant to solar energy applications. The dependence of emittance and absorptance on the real and imaginary components of the refractive index and on the geometric structure of the surface layer is quite complex. However, a number of generalizations concerning the radiative properties of opaque surfaces are possible. These are summarized in the following discussion.

Polished Metals

1. In the infrared region, the magnitude of the monochromatic emissivity ε_λ is small and is dependent on free-electron contributions. Emissivity is also a function of the ratio of resistivity to wavelength r/λ, as depicted in Fig. 5-11. At shorter wavelengths, bound-electron contributions become significant, ε_λ is larger in magnitude, and it sometimes exhibits a maximum value. In the visible spectrum, common values for ε_λ are 0.4 to 0.8 and ε_λ decreases slightly as temperature increases. For $0.7 < \lambda < 1.5$ μm, ε_λ is approximately independent of temperature. For $\lambda > 8$ μm, ε_λ is approximately proportional to the square root of temperature since $\varepsilon_\lambda \propto \sqrt{r}$ and $r \propto T$. Here the Drude or Hagen-Rubens relation applies, that is, $\varepsilon_{\lambda,n} \approx 0.0365\sqrt{r/\lambda}$, where r has units of ohm-meters and λ is measured in micrometers.

2. Total emittance is substantially proportional to absolute temperature, and at moderate temperatures $\varepsilon_n = 0.058T\sqrt{rT}$, where T is measured in kelvins.

3. The total absorptance of a metal at temperature T_1 with respect to radiation from a black or gray source at temperature T_2 is equal to the emissivity evaluated at the geometric mean of T_1 and T_2. Figure 5-11 gives values of ε_λ and $\varepsilon_{\lambda,n}$, and their ratio, as a function of the product rT (solid lines). Although Fig. 5-11 is based on free-electron

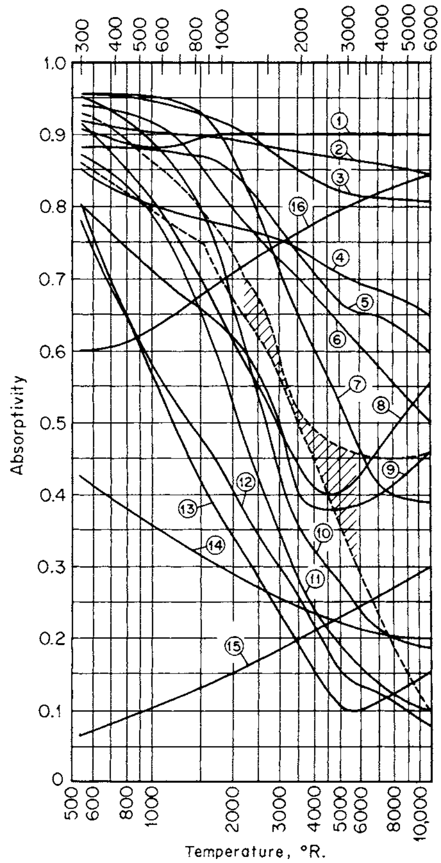

FIG. 5-10 Variation of absorptivity with temperature of radiation source. (1) Slate composition roofing. (2) Linoleum, red brown. (3) Asbestos slate. (4) Soft rubber, gray. (5) Concrete. (6) Porcelain. (7) Vitreous enamel, white. (8) Red brick. (9) Cork. (10) White dutch tile. (11) White chamotte. (12) MgO, evaporated. (13) Anodized aluminum. (14) Aluminum paint. (15) Polished aluminum. (16) Graphite. The two dashed lines bound the limits of data on gray paving brick, asbestos paper, wood, various cloths, plaster of paris, lithopone, and paper. To convert degrees Rankine to kelvins, multiply by (5.556)(10^{-1}).

*In the literature, *emittance* and *emissivity* are often used interchangeably. NIST (the National Institute of Standards and Technology) recommends use of the suffix *-ivity* for pure materials with optically smooth surfaces, and *-ance* for rough and contaminated surfaces. Most real engineering materials fall into the latter category.

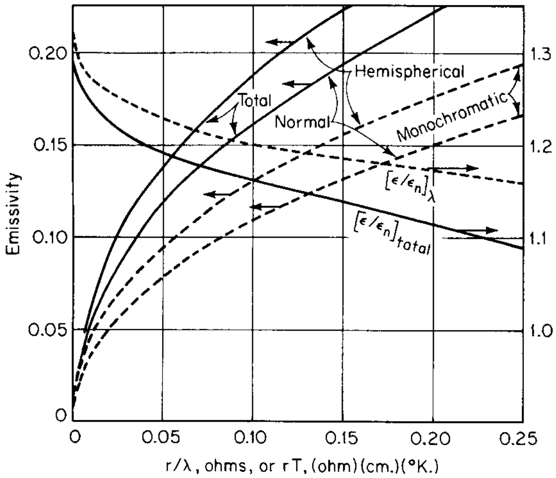

FIG. 5-11 Hemispherical and normal emissivities of metals and their ratio. Dashed lines: monochromatic (spectral) values versus r/λ. Solid lines: total values versus rT. To convert ohm-centimeter-kelvins to ohm-meter-kelvins, multiply by 10^{-2}.

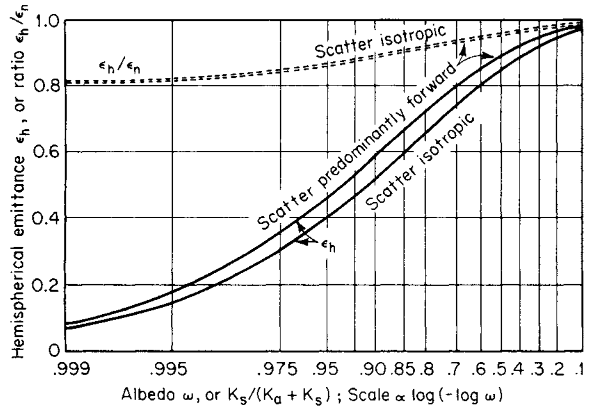

FIG. 5-12 Hemispherical emittance ε_h and the ratio of hemispherical to normal emittance $\varepsilon_h/\varepsilon_n$ for a semi-infinite absorbing-scattering medium.

contributions to emissivity in the far infrared, the relations for total emissivity are remarkably good even at high temperatures. Unless extraordinary efforts are taken to prevent oxidation, a metallic surface may exhibit an emittance or absorptance which may be several times that of a polished specimen. For example, the emittance of iron and steel depends strongly on the degree of oxidation and roughness. Clean iron and steel surfaces have an emittance from 0.05 to 0.45 at ambient temperatures and 0.4 to 0.7 at high temperatures. Oxidized and/or roughened iron and steel surfaces have values of emittance ranging from 0.6 to 0.95 at low temperatures to 0.9 to 0.95 at high temperatures.

Refractory Materials For refractory materials, the dependence of emittance and absorptance on grain size and impurity concentrations is quite important.

1. Most refractory materials are characterized by $0.8 < \varepsilon_\lambda < 1.0$ for the wavelength region $2 < \lambda < 4$ μm. The monochromatic emissivity ε_λ decreases rapidly toward shorter wavelengths for materials that are white in the visible range but demonstrates high values for black materials such as FeO and Cr_2O_3. Small concentrations of FeO and Cr_2O_3, or other colored oxides, can cause marked increases in the emittance of materials that are normally white. The sensitivity of the emittance of refractory oxides to small additions of absorbing materials is demonstrated by the results of calculations presented in Fig. 5-12. Figure 5-12 shows the emittance of a semi-infinite absorbing-scattering medium as a function of its *albedo* $\omega \equiv K_S/(K_a + K_S)$, where K_a and K_S are the scatter and absorption coefficients, respectively. These results are relevant to the radiative properties of fibrous materials, paints, oxide coatings, refractory materials, and other *particulate* media. They demonstrate that over the relatively small range $1 - \omega = 0.005$ to 0.1, the hemispherical emittance ε_h increases from approximately 0.15 to 1.0. For refractory materials, ε_λ varies little with temperature, with the exception of some white oxides which at high temperatures become good emitters in the visible spectrum as a consequence of the induced electronic transitions.

2. For refractory materials at ambient temperatures, the total emittance ε is generally high (0.7 to 1.0). Total refractory emittance decreases with increasing temperature, such that a temperature increase from 1000 to 1570°C may result in a 20 to 30 percent reduction in ε.

3. Emittance and absorptance increase with increase in grain size over a grain size range of 1 to 200 μm.

4. The ratio $\varepsilon_h/\varepsilon_n$ of hemispherical to normal emissivity of polished surfaces varies with refractive index n; e.g., the ratio decreases from a value of 1.0 when $n = 1.0$ to a value of 0.93 when $n = 1.5$ (common glass) and increases back to 0.96 at $n = 3.0$.

5. As shown in Fig. 5-12, for a surface composed of particulate matter which scatters isotropically, the ratio $\varepsilon_h/\varepsilon_n$ varies from 1.0 when $\omega < 0.1$ to about 0.8 when $\omega = 0.999$.

6. The total absorptance exhibits a decrease with an increase in temperature of the radiation source similar to the decrease in emittance with an increase in the emitter temperature.

Figure 5-10 shows a regular variation of $\alpha_{1,2}$ with T_2. When T_2 is not very different from T_1, $\alpha_{1,2} = \varepsilon_1(T_2/T_1)^m$. It may be shown that Eq. (5-107*b*) is then approximated by

$$Q_{1,2} = (1 + m/4)\varepsilon_{av} A_1 \sigma(T_1^4 - T_2^4) \tag{5-110}$$

where ε_{av} is evaluated at the arithmetic mean of T_1 and T_2. For metals $m \approx 0.5$ while for nonmetals m is small and negative.

Table 5-4 illustrates values of emittance for materials encountered in engineering practice. It is based on a critical evaluation of early emissivity data. Table 5-4 demonstrates the wide variation possible in the emissivity of a particular material due to variations in surface roughness and thermal pretreatment. With few exceptions the data in Table 5-4 refer to emittances ε_n normal to the surface. The hemispherical emittance ε_h is usually slightly smaller, as demonstrated by the ratio $\varepsilon_h/\varepsilon_n$ depicted in Fig. 5-12. More recent data support the range of emittance values given in Table 5-4 and their dependence on surface conditions. An extensive compilation is provided by Goldsmith, Waterman, and Hirschorn (*Thermophysical Properties of Matter*, Purdue University, Touloukian, ed., Plenum, 1970–1979).

For opaque materials the reflectance ρ is the complement of the absorptance. The directional distribution of the reflected radiation depends on the material, its degree of roughness or grain size, and, if a metal, its state of oxidation. Polished surfaces of homogeneous materials are specular reflectors. In contrast, the intensity of the radiation reflected from a perfectly diffuse or *Lambert surface* is independent of direction. The directional distribution of reflectance of many oxidized metals, refractory materials, and natural products approximates that of a perfectly diffuse reflector. A better model, adequate for many calculation purposes, is achieved by assuming that the total reflectance is the sum of diffuse and specular components ρ_D and ρ_S, as discussed in a subsequent section.

VIEW FACTORS AND DIRECT EXCHANGE AREAS

Consider radiative interchange between two *finite* black surface area elements A_1 and A_2 separated by a transparent medium. Since they are black, the surfaces emit isotropically and totally absorb all incident radiant energy. It is desired to compute the fraction of radiant energy, per unit emissive power E_1, leaving A_1 in all directions which is intercepted and absorbed by A_2. The required quantity is defined as the **direct view factor** and is assigned the notation $F_{1,2}$. Since the *net radiant energy interchange* $Q_{1,2} \equiv A_1F_{1,2}E_1 - A_2F_{2,1}E_2$ *between* surfaces A_1 and A_2 must be zero when their temperatures are equal, it follows

TABLE 5-4 Normal Total Emissivity of Various Surfaces

A. Metals and Their Oxides

Surface	*t*, °F*	Emissivity*
Aluminum		
Highly polished plate, 98.3% pure	440–1070	0.039–0.057
Polished plate	73	0.040

*When two temperatures and two emissivities are given, they correspond, first to first and second to second, and linear interpolation is permissible. °C = (°F − 32)/1.8.

†Although this value is probably high, it is given for comparison with the data by the same investigator to show the effect of oil layers. See Aluminum, Part A of this table.

thermodynamically that $A_1F_{1,2} = A_2F_{2,1}$. The product of area and view factor $\overline{s_1s_2} \equiv A_1F_{1,2}$, which has the dimensions of area, is termed the **direct surface-to-surface exchange area** for finite black surfaces. Clearly, direct exchange areas are symmetric with respect to their subscripts, that is, $\overline{s_is_j} = \overline{s_js_i}$, but view factors are not symmetric unless the associated surface areas are equal. This property is referred to as the **symmetry** or **reciprocity relation** for direct exchange areas. The shorthand notation $\overline{s_1s_2} \equiv \overline{12} = \overline{21}$ for direct exchange areas is often found useful in mathematical developments.

Equation (5-101) may also be restated as

$$\frac{\partial^2 \overline{s_is_j}}{\partial A_i\,\partial A_j} = \frac{\cos\phi_i \cos\phi_j}{\pi r^2} \qquad (5\text{-}111)$$

which leads directly to the required definition of the direct exchange area as a double surface integral

$$\overline{s_is_j} = \oiint_{A_i}\oiint_{A_j} \frac{\cos\phi_i \cos\phi_j}{\pi r^2}\, dA_j\, dA_i \qquad (5\text{-}112)$$

All terms in Eq. (5-112) have been previously defined.

Suppose now that Eq. (5-112) is integrated over the entire confining surface of an **enclosure** which has been subdivided into M finite area elements. Each of the M surface *zones* must then satisfy certain **conservation relations** involving *all* the direct exchange areas in the enclosure

$$\sum_{j=1}^{M} \overline{s_is_j} = A_i \quad \text{for } 1 \le i \le M \qquad (5\text{-}113a)$$

or in terms of view factors

$$\sum_{j=1}^{M} F_{i,j} = 1 \quad \text{for } 1 \le i \le M \qquad (5\text{-}113b)$$

Contour integration is commonly used to simplify the evaluation of Eq. (5-112) for specific geometries; see Modest (op. cit., Chap. 4) or Siegel and Howell (op. cit., Chap. 5). The formulas for two particularly useful view factors involving perpendicular rectangles of area xz and yz with common edge z and equal parallel rectangles of area xy and distance of separation z are given for **perpendicular rectangles** with common dimension z

$$(\pi\cdot X)\cdot F_{X,Y} = X\tan^{-1}\frac{1}{X} + Y\tan^{-1}\frac{1}{Y} - \sqrt{X^2+Y^2}\tan^{-1}\sqrt{\frac{1}{X^2+Y^2}}$$
$$+ \frac{1}{4}\ln\left\{\frac{(1+X^2)(1+Y^2)}{1+X^2+Y^2}\left[\frac{X^2(1+X^2+Y^2)}{(1+X^2)(X^2+Y^2)}\right]^{X^2}\left[\frac{Y^2(1+X^2+Y^2)}{(1+Y^2)(X^2+Y^2)}\right]^{Y^2}\right\} \qquad (5\text{-}114a)$$

and for **parallel rectangles**, separated by distance z,

$$\left(\frac{\pi\cdot X\cdot Y}{2}\right)\cdot F_{X,Y} = \ln\left[\frac{(1+X^2)(1+Y^2)}{1+X^2+Y^2}\right]^{1/2} + X\sqrt{1+Y^2}\tan^{-1}\frac{X}{\sqrt{1+Y^2}}$$
$$+ Y\sqrt{1+X^2}\tan^{-1}\frac{Y}{\sqrt{1+X^2}} - X\tan^{-1}X - Y\tan^{-1}Y \qquad (5\text{-}114b)$$

In Eqs. (5-114) X and Y are normalized whereby $X = x/z$ and $Y = y/z$ and the corresponding *dimensional* direct surface areas are given by $\overline{s_xs_y} = xzF_{X,Y}$ and $\overline{s_xs_y} = xyF_{X,Y}$, respectively.

The exchange area between any two area elements of a sphere is independent of their relative shape and position and is simply the product of the areas, divided by the area of the entire sphere; i.e., any spot on a sphere has equal views of all other spots.

Figure 5-13, curves 1 through 4, shows view factors for selected parallel opposed disks, squares, and 2:1 rectangles and parallel rectangles with one infinite dimension as a function of the ratio of the

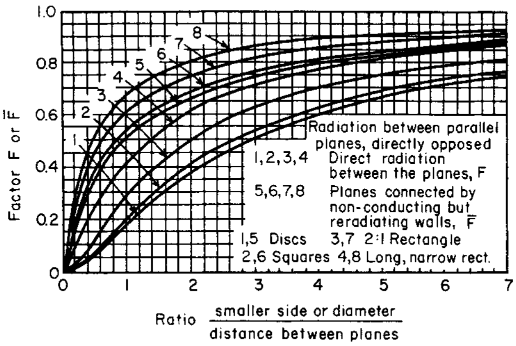

FIG. 5-13 Radiation between parallel planes, directly opposed.

smaller diameter or side to the distance of separation. Curves 2 through 4 of Fig. 5-13, for opposed rectangles, can be computed with Eq. (5-114*b*). The view factors for two finite coaxial coextensive cylinders of radii $r \le R$ and height L are shown in Fig. 5-14. The direct view factors for an infinite plane parallel to a system of rows of parallel tubes (see Fig. 5-16) are given as curves 1 and 3 of Fig. 5-15. The view factors for this two-dimensional geometry can be readily calculated by using the **crossed-strings method.**

The crossed-strings method, due to Hottel (*Radiative Transfer*, McGraw-Hill, New York, 1967), is stated as follows: "The exchange area for two-dimensional surfaces, A_1 and A_2, per unit length (in the infinite dimension) is given by the sum of the lengths of crossed strings from the ends of A_1 to the ends of A_2 less the sum of the uncrossed strings from and to the same points all divided by 2." The strings must be drawn so that all the flux from one surface to the other must cross each of a pair of crossed strings and neither of the pair of uncrossed strings. If one surface can see the other around both sides of an obstruction, two more pairs of strings are involved. The calculation procedure is demonstrated by evaluation of the tube-to-tube view factor for one row of a tube bank, as illustrated in Example 7.

Example 7: The Crossed-Strings Method Figure 5-16 depicts the transverse cross section of two infinitely long, parallel circular tubes of diameter D and center-to-center distance of separation C. Use the crossed-strings method to formulate the tube-to-tube direct exchange area and view factor $\overline{s_ts_t}$ and $F_{t,t}$, respectively.

Solution: The circumferential area of each tube is $A_t = \pi D$ per unit length in the infinite dimension for this two-dimensional geometry. Application of the crossed-strings procedure then yields simply

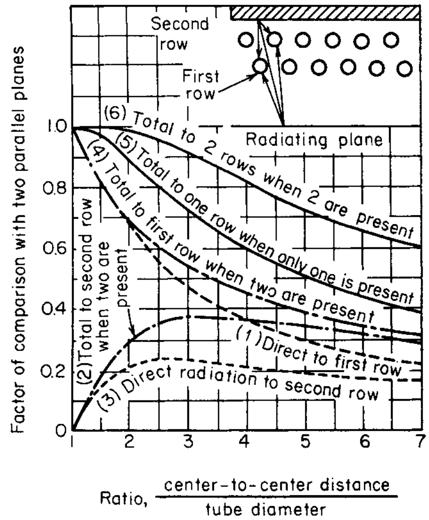

FIG. 5-15 Distribution of radiation to rows of tubes irradiated from one side. Dashed lines: direct view factor F from plane to tubes. Solid lines: total view factor $\bar{F}$ for black tubes backed by a refractory surface.

$$\overline{s_ts_t} = \frac{2(EFGH - HJ)}{2} = D[\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R]$$

and $$F_{t,t} = \overline{s_ts_t}/A_t = [\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R]/\pi$$

where $EFGH$ and $HJ = C$ are the indicated line segments and $R \equiv C/D \ge 1$. Curve 1 of Fig. 5-15, denoted by $F_{p,t}$, is a function of $F_{t,t}$, that is, $F_{p,t} = (\pi/R)(\frac{1}{2} - F_{t,t})$.

The **Yamauti principle** [Yamauti, *Res. Electrotech Lab. (Tokyo)*, **148** (1924); **194** (1927); **250** (1929)] is stated as follows; *The exchange areas between two pairs of surfaces are equal when there is a one-to-one correspondence for all sets of symmetrically positioned pairs of differential elements in the two surface combinations*. Figure 5-17 illustrates the Yamauti principle applied to surfaces in perpendicular planes having a common edge. With reference to Fig. 5-17, the Yamauti principle states that the diagonally opposed exchange areas are equal, that is, $\overline{(1)(4)} = \overline{(2)(3)}$. Figure 5-17 also shows a more complex geometric construction for displaced cylinders for which the Yamauti principle also applies. Collectively the three terms *reciprocity* or *symmetry principle, conservation*

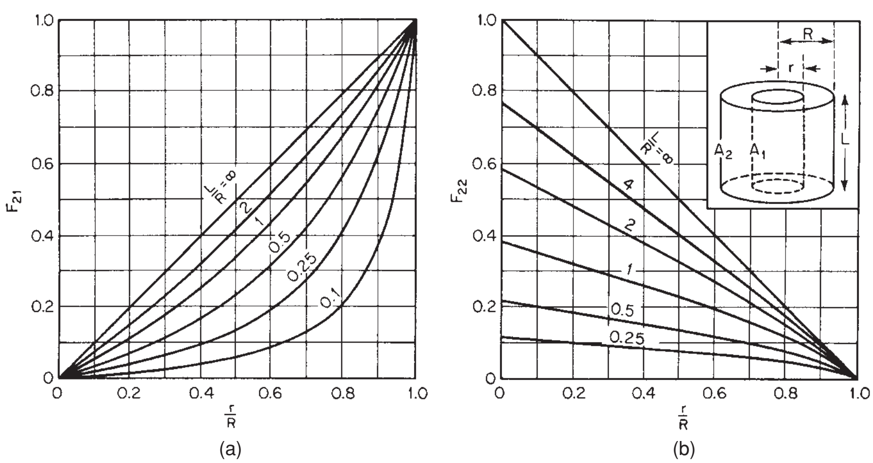

FIG. 5-14 View factors for a system of two concentric coaxial cylinders of equal length. (*a*) Inner surface of outer cylinder to inner cylinder. (*b*) Inner surface of outer cylinder to itself.

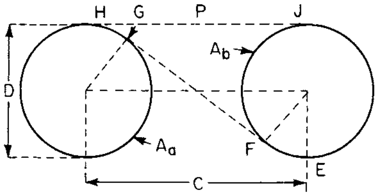

FIG. 5-16 Direct exchange between parallel circular tubes.

principle, and *Yamauti principle* are referred to as **view factor or exchange area algebra.**

Example 8: Illustration of Exchange Area Algebra Figure 5-17 shows a graphical construction depicting four perpendicular opposed rectangles with a common edge. *Numerically* evaluate the direct exchange areas and view factors for the diagonally opposed (shaded) rectangles A_1 and A_4, that is, $\overline{(1)(4)}$, as well as $\overline{(1)(3+4)}$. The dimensions of the rectangular construction are shown in Fig. 5-17 as $x = 3$, $y = 2$, and $z = 1$.

Solution: Using shorthand notation for direct exchange areas, the conservation principle yields

$$\overline{(1+2)(3+4)} = \overline{(1+2)(3)} + \overline{(1+2)(4)} = \overline{(1)(3)} + \overline{(2)(3)} + \overline{(1)(4)} + \overline{(2)(4)}$$

Now by the Yamauti principle we have $\overline{(1)(4)} \equiv \overline{(2)(3)}$. Combination of these two relations yields the first result $\overline{(1)(4)} = [\overline{(1+2)(3+4)} - \overline{(1)(3)} - \overline{(2)(4)}]/2$. For $\overline{(1)(3+4)}$, again conservation yields $\overline{(1)(3+4)} = \overline{(1)(3)} + \overline{(1)(4)}$, and substitution of the expression for $\overline{(1)(4)}$ just obtained yields the second result, that is, $\overline{(1)(3+4)} = [\overline{(1+2)(3+4)} + \overline{(1)(3)} - \overline{(2)(4)}]/2.0$. All three required direct exchange areas in these two relations are readily evaluated from Eq. (5-114*a*). Moreover, these equations apply to opposed *parallel* rectangles as well as rectangles with a common edge oriented at *any angle*. Numerically it follows from Eq. (5-114*a*) that for $X = \frac{1}{3}$, $Y = \frac{2}{3}$, and $z = 3$ that $\overline{(1+2)(3+4)} = 0.95990$; for $X = 1$, $Y = 2$, and $z = 1$ that $\overline{(1)(3)} = 0.23285$; and for $X = ½$, $Y = 1$, and $z = 2$ that $\overline{(2)(4)} = 0.585747$. Since $A_1 = 1.0$, this leads to $\overline{s_1 s_4} = F_{1,4} = (0.95990 - 0.23285 - 0.584747)/2.0 = 0.07115$ and $\overline{s_1 s_{3+4}} = F_{1,3+4} = (0.95990 + 0.23285 - 0.584747)/2.0 = 0.30400$.

Many literature sources document closed-form algebraic expressions for view factors. Particularly comprehensive references include the compendia by Modest (op. cit., App. D) and Siegel and Howell (op. cit., App. C). The appendices for both of these textbooks also provide a wealth of resource information for radiative transfer. Appendix F of Modest, e.g., references an extensive listing of Fortan computer codes for a variety of radiation calculations which include view factors. These codes are archived in the dedicated Internet web site maintained by the publisher. The textbook by Siegel and Howell also includes an extensive database of view factors archived on a CD-ROM and includes a reference to an author-maintained Internet web site. Other historical sources for view factors include Hottel and Sarofim (op. cit., Chap. 2) and Hamilton and Morgan (NACA-TN 2836, December 1952).

RADIATIVE EXCHANGE IN ENCLOSURES—THE ZONE METHOD

Total Exchange Areas When an enclosure contains *reflective* surface zones, allowance must be made for not only the radiant energy transferred *directly* between any two zones but also the additional transfer attendant to *however many multiple reflections* which occur among the intervening reflective surfaces. Under such circumstances,

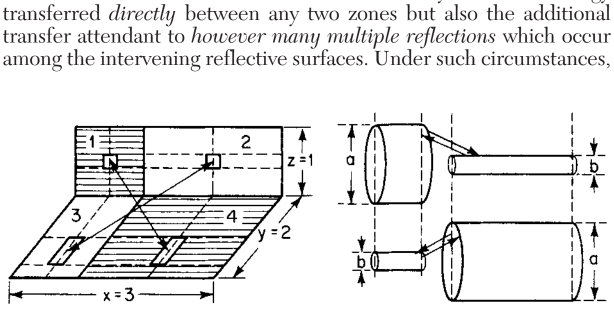

FIG. 5-17 Illustration of the Yamauti principle.

it can be shown that the *net* radiative flux $Q_{i,j}$ between all such surface zone pairs A_i and A_j, making full allowance for all multiple reflections, may be computed from

$$Q_{i,j} = \sigma(A_i \mathcal{F}_{i,j} T_j^4 - A_j \mathcal{F}_{j,i} T_i^4) \tag{5-115}$$

Here, $\mathcal{F}_{i,j}$ is defined as the **total surface-to-surface view factor** *from* A_i to A_j, and the quantity $\overline{S_i S_j} \equiv A_i \mathcal{F}_{i,j}$ is defined as the corresponding **total surface-to-surface exchange area**. In analogy with the direct exchange areas, the total surface-to-surface exchange areas are also symmetric and thus obey reciprocity, that is, $A_i \mathcal{F}_{i,j} = A_j \mathcal{F}_{j,i}$ or $\overline{S_i S_j} = \overline{S_j S_i}$. When applied to an enclosure, *total* exchange areas and view factors also must satisfy appropriate conservation relations. Total exchange areas are functions of the *geometry and radiative properties of the entire enclosure.* They are also independent of temperature if all surfaces and any radiatively participating media are gray. The following subsection presents a general **matrix method** for the *explicit* evaluation of total exchange areas from direct exchange areas and other enclosure parameters.

In what follows, conventional matrix notation is strictly employed as in $\mathbf{A} = [a_{i,j}]$ wherein the scalar subscripts always denote the row and column indices, respectively, and all **matrix entities** defined here are denoted by **boldface** notation. Section 3 of this handbook, "Mathematics," provides an especially convenient reference for introductory matrix algebra and matrix computations.

General Matrix Formulation The **zone method** is perhaps the simplest numerical quadrature of the governing *integral equations* for radiative transfer. It may be derived from first principles by starting with the *equation of transfer* for radiation intensity. The zone method *always conserves radiant energy* since the spatial discretization utilizes macroscopic energy balances involving *spatially averaged* radiative flux quantities. Because large sets of linear algebraic equations can arise in this process, *matrix algebra* provides the most compact notation and the most expeditious methods of solution. The mathematical approach presented here is a matrix generalization of the original *(scalar)* development of the zone method due to Hottel and Sarofim (op. cit.). The present matrix development is abstracted from that introduced by Noble [Noble, J. J., *Int. J. Heat Mass Transfer*, **18,** 261–269 (1975)].

Consider an arbitrary three-dimensional enclosure of total volume V and surface area A which confines an absorbing-emitting medium (gas). Let the enclosure be subdivided (zoned) into M finite surface area and N finite volume elements, each small enough that all such *zones* are substantially isothermal. The mathematical development in this section is restricted by the following conditions and/or assumptions:

1. The gas temperatures are given a priori.
2. Allowance is made for gas-to-surface radiative transfer.
3. Radiative transfer with respect to the confined gas is either monochromatic or gray. The gray gas absorption coefficient is denoted here by $K(\text{m}^{-1})$. In subsequent sections the monochromatic absorption coefficient is denoted by $K_\lambda(\lambda)$.
4. All surface emissivities are assumed to be gray and thus independent of temperature.
5. Surface emission and reflection are isotropic or diffuse.
6. The gas does not scatter.

Noble (op. cit.) has extended the present matrix methodology to the case where the gaseous absorbing-emitting medium also *scatters isotropically*.

In matrix notation the blackbody emissive powers for all surface and volume zones comprising the zoned enclosure are designated as $\mathbf{E} = [E_i] = [\sigma T_i^4]$, an $M \times 1$ vector, and $\mathbf{E}_g = [E_{g,i}] = [\sigma T_{g,i}^4]$, an $N \times 1$ vector, respectively. Moreover, all surface zones are characterized by three $M \times M$ diagonal matrices for zone area $\mathbf{AI} = [A_i \cdot \delta_{i,j}]$, diffuse emissivity $\varepsilon\mathbf{I} = [\varepsilon_i \cdot \delta_{i,j}]$, and diffuse reflectivity, $\rho\mathbf{I} = [(1 - \varepsilon_i) \cdot \delta_{i,j}]$, respectively . Here $\delta_{i,j}$ is the **Kronecker delta** (that is, $\delta_{i,j} = 1$ for $i = j$ and $\delta_{i,j} = 0$ for $i \neq j$).

Two arrays of direct exchange areas are now defined; i.e., the matrix $\overline{\mathbf{ss}} = [\overline{s_i s_j}]$ is the $M \times M$ array of **direct surface-to-surface exchange areas,** and the matrix $\overline{\mathbf{sg}} = [\overline{s_i g_j}]$ is the $M \times N$ array of **direct gas-to-surface exchange areas.** Here the scalar elements of $\overline{\mathbf{ss}}$ and $\overline{\mathbf{sg}}$ are computed from the integrals

$$\overline{s_i s_j} = \oint\!\!\oint_{A_i} \oint\!\!\oint_{A_j} \frac{e^{-Kr}}{\pi r^2} \cos\phi_i \cos\phi_j \, dA_j \, dA_i \tag{5-116a}$$

$$\overline{s_i g_j} = \oiint_{A_i} \iiint_{V_j} K \frac{e^{-Kr}}{\pi r^2} \cos \phi i \, dV_j \, dA_i \qquad (5\text{-}116b)$$

Equation (5-116*a*) is a generalization of Eq. (5-112) for the case $K \neq 0$ while $\overline{s_i g_j}$ is a new quantity, which arises *only* for the case $K \neq 0$.

Matrix characterization of the radiative energy balance at each surface zone is facilitated via definition of three $M \times 1$ vectors; the radiative surface fluxes $\mathbf{Q} = [Q_i]$, with units of watts; and the vectors $\mathbf{H} = [H_i]$ and $\mathbf{W} = [W_i]$ both having units of W/m². The arrays **H** and **W** define the *incident* and *leaving* flux *densities*, respectively, at each surface zone. The variable **W** is also referred to in the literature as the **radiosity** or **exitance.** Since $\mathbf{W} \equiv \varepsilon\mathbf{I}\cdot\mathbf{E} + \rho\mathbf{I}\cdot\mathbf{H}$, the radiative flux at each surface zone is also defined in terms of **E, H,** and **W** by three equivalent matrix relations, namely,

$$\mathbf{Q} = \mathbf{AI}\cdot[\mathbf{W} - \mathbf{H}] = \varepsilon\mathbf{AI}\cdot[\mathbf{E} - \mathbf{H}] = \rho\mathbf{I}^{-1}\cdot\varepsilon\mathbf{AI}\cdot[\mathbf{E} - \mathbf{W}] \qquad (5\text{-}117)$$

where the third form is valid *if and only if the matrix inverse* $\rho\mathbf{I}^{-1}$ *exists*. Two other ancillary matrix expressions are

$$\varepsilon\mathbf{AI}\cdot\mathbf{E} = \rho\mathbf{I}\cdot\mathbf{Q} + \varepsilon\mathbf{AI}\cdot\mathbf{W} \quad \text{and} \quad \mathbf{AI}\cdot\mathbf{H} = \overline{\mathbf{ss}}\cdot\mathbf{W} + \overline{\mathbf{sg}}\cdot\mathbf{E}_g \qquad (5\text{-}117a,b)$$

which lead to

$$\varepsilon\mathbf{I}\cdot\mathbf{E} = [\mathbf{I} - \rho\mathbf{I}\cdot\mathbf{AI}^{-1}\cdot\overline{\mathbf{ss}}]\cdot\mathbf{W} - \rho\mathbf{I}\cdot\mathbf{AI}^{-1}\,\overline{\mathbf{sg}}\cdot\mathbf{E}_g. \qquad (5\text{-}117c)$$

The latter relation is especially useful in radiation pyrometry where true wall temperatures must be computed from wall radiosities.

Explicit Matrix Solution for Total Exchange Areas For gray or monochromatic transfer, the **primary working relation** for zoning calculations via the matrix method is

$$\mathbf{Q} = \varepsilon\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{E} - \overline{\mathbf{SS}}\cdot\mathbf{E} - \overline{\mathbf{SG}}\cdot\mathbf{E}_g \qquad [M \times 1] \qquad (5\text{-}118)$$

Equation (5-118) makes full allowance for multiple reflections in an enclosure of any degree of complexity. To apply Eq. (5-118) for design or simulation purposes, the gas temperatures must be known and surface boundary conditions must be specified for each and every surface zone in the form of *either* E_i or Q_i. In application of Eq. (5-118), *physically impossible values* of E_i may well result if *physically unrealistic* values of Q_i are specified.

In Eq. (5-118), $\overline{\mathbf{SS}}$ and $\overline{\mathbf{SG}}$ are defined as the *required* arrays of **total surface-to-surface exchange areas** and **total gas-to-surface exchange areas,** respectively. The matrices for total exchange areas are calculated *explicitly* from the corresponding arrays of direct exchange areas and the other enclosure parameters by the following matrix formulas:

Surface-to-surface exchange $\quad \overline{\mathbf{SS}} = \varepsilon\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\overline{\mathbf{ss}}\cdot\varepsilon\mathbf{I} \quad [M \times M] \quad$ (5-118*a*)

Gas-to-surface exchange $\quad \overline{\mathbf{SG}} = \varepsilon\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\overline{\mathbf{sg}} \quad [M \times N] \quad$ (5-118*b*)

where in Eqs. (5-118), **R** is the explicit **inverse reflectivity matrix,** defined as

$$\mathbf{R} = [\mathbf{AI} - \overline{\mathbf{ss}}\cdot\rho\mathbf{I}]^{-1} \qquad [M \times M] \qquad (5\text{-}118c)$$

While the **R** matrix is generally not symmetric, the matrix product $\rho\mathbf{I}\cdot\mathbf{R}$ is *always* symmetric. This fact proves useful for error checking.

The most computationally significant aspect of the matrix method is that the inverse reflectivity matrix **R** *always exists* for any physically meaningful enclosure problem. More precisely, **R** always exists provided that $K \neq 0$. For a transparent medium, **R** exists provided that there *formally* exists at least one surface zone A_i such that $\varepsilon_i \neq 0$. An important computational corollary of this statement for *transparent media* is that the matrix $[\mathbf{AI} - \overline{\mathbf{ss}}]$ is *always singular* and demonstrates *matrix rank* $M - 1$ (Noble, op. cit.).

Finally, the four matrix arrays $\overline{\mathbf{ss}}$, $\overline{\mathbf{gs}}$, $\overline{\mathbf{SS}}$, and $\overline{\mathbf{SG}}$ of direct and total exchange areas must satisfy **matrix conservation relations,** i.e.,

Direct exchange areas $\quad \mathbf{AI}\cdot\mathbf{1}_M = \overline{\mathbf{ss}}\cdot\mathbf{1}_M + \overline{\mathbf{sg}}\cdot\mathbf{1}_N \quad$ (5-119*a*)

Total exchange areas $\quad \varepsilon\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{1}_M = \overline{\mathbf{SS}}\cdot\mathbf{1}_M + \overline{\mathbf{SG}}\cdot\mathbf{1}_N \quad$ (5-119*b*)

Here $\mathbf{1}_M$ is an $M \times 1$ column vector all of whose elements are unity. If $\varepsilon\mathbf{I} = \mathbf{I}$ or equivalently, $\rho\mathbf{I} = \mathbf{0}$, Eq. (5-118*c*) reduces to $\mathbf{R} = \mathbf{AI}^{-1}$ with the result that Eqs. (5-118*a*) and (5-118*b*) degenerate to simply $\overline{\mathbf{SS}} = \overline{\mathbf{ss}}$ and $\overline{\mathbf{SG}} = \overline{\mathbf{sg}}$. Further, while the array **SS** is always symmetric, the array **SG** is generally not square.

For purposes of digital computation, it is good practice to enter all data for direct exchange surface-to-surface areas $\overline{\mathbf{ss}}$ with a precision of *at least* five significant figures. This need arises because all the scalar elements of $\overline{\mathbf{sg}}$ can be calculated *arithmetically* from appropriate direct surface-to-surface exchange areas by using view factor algebra rather than via the definition of the defining integral, Eq. (5-116*b*). This process often involves small arithmetic differences between two numbers of nearly equal magnitude, and numerical significance is easily lost.

Computer implementation of the matrix method proves straightforward, given the availability of modern software applications. In particular, several especially user-friendly GUI mathematical utilities are available that perform matrix computations using *essentially algebraic notation*. Many simple zoning problems may be solved with spreadsheets. For large M and N, the matrix method can involve management of a large amount of data. Error checks based on symmetry and conservation by calculation of the row sums of the four arrays of direct and total exchange areas then prove indispensable.

Zone Methodology and Conventions For a transparent medium, no more than $\Sigma = M(M-1)/2$ of the M^2 elements of the $\overline{\mathbf{ss}}$ array are *unique*. Further, surface zones are characterized into two generic types. **Source-sink zones** are defined as those for which temperature is specified and whose radiative flux Q_i is to be determined. For **flux zones,** conversely, these conditions are reversed. When both types of zone are present in an enclosure, Eq. (5-118) may be *partitioned* to produce a more efficient computational algorithm. Let $M = M_s + M_f$ represent the total number of surface zones where M_s is the number of source-sink zones and M_f is the number of flux zones. The flux zones are the *last to be numbered.* Equation (5-118) is then partitioned as follows:

$$\begin{bmatrix}\mathbf{Q}_1\\ \mathbf{Q}_2\end{bmatrix} = \begin{bmatrix}\varepsilon\mathbf{AI}_{1,1} & \mathbf{0}\\ \mathbf{0} & \varepsilon\mathbf{AI}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overline{\mathbf{SS}}_{1,1} & \overline{\mathbf{SS}}_{1,2}\\ \overline{\mathbf{SS}}_{2,1} & \overline{\mathbf{SS}}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overline{\mathbf{SG}}_1\\ \overline{\mathbf{SG}}_2\end{bmatrix}\cdot\mathbf{E}_g \qquad (5\text{-}120)$$

Here the dimensions of the submatrices $\varepsilon\mathbf{AI}_{1,1}$ and $\overline{\mathbf{SS}}_{1,1}$ are both $M_s \times M_s$ and $\overline{\mathbf{SG}}_1$ has dimensions $M_s \times N$. Partition algebra then yields the following two matrix equations for $\mathbf{Q}_1$, the $M_s \times 1$ vector of unknown source-sink fluxes and $\mathbf{E}_2$, the $M_f \times 1$ vector of unknown emissive powers for the flux zones, i.e.,

$$\mathbf{E}_2 = [\varepsilon\mathbf{AI}_{2,2} - \overline{\mathbf{SS}}_{2,2}]^{-1}\cdot[\mathbf{Q}_2 + \overline{\mathbf{SS}}_{2,1}\cdot\mathbf{E}_1 + \overline{\mathbf{SG}}_2\cdot\mathbf{E}_g] \qquad (5\text{-}120a)$$

$$\mathbf{Q}_1 = \varepsilon\mathbf{AI}_{1,1}\cdot\mathbf{E}_1 - \overline{\mathbf{SS}}_{1,1}\cdot\mathbf{E}_1 - \overline{\mathbf{SS}}_{1,2}\cdot\mathrm{E}_2 - \overline{\mathbf{SG}}_1\cdot\mathbf{E}_g \qquad (5\text{-}120b)$$

The inverse matrix in Eq. (5-120*a*) formally does not exist if there is at least one flux zone such that $\varepsilon_i = 0$. However, well-behaved results are usually obtained with Eq. (5-120*a*) by utilizing a *notional zero*, say, $\varepsilon_i \approx 10^{-5}$, to simulate $\varepsilon_i = 0$. Computationally, $\mathbf{E}_2$ is first obtained from Eq. (5-120*a*) and then substituted into either Eq. (5-120*b*) or Eq. (5-118).

Surface zones need not be *contiguous.* For example, in a symmetric enclosure, zones on opposite sides of the plane of symmetry may be "lumped" into a single zone for computational purposes. Lumping nonsymmetrical zones is also possible as long as the zone temperatures and emissivities are equal.

An **adiabatic refractory surface** of area A_r and emissivity ε_r, for which $Q_r = 0$, proves quite important in practice. A nearly radiatively adiabatic refractory surface occurs when differences between internal conduction and convection and external heat losses through the refractory wall are small compared with the *magnitude* of the *incident* and *leaving* radiation fluxes. For *any* surface zone, the radiant flux is given by $Q = A(W - H) = \varepsilon A(E - H)$ and $Q = \varepsilon A/\rho(E - W)$ (if $\rho \neq 0$). These equations then lead to the result that if $Q_r = 0$, $E_r = H_r = W_r$ *for all* $0 \le \varepsilon_r \le 1$. *Sufficient conditions* for modeling an adiabatic refractory zone are thus *either* to put $\varepsilon_r = 0$ *or* to specify *directly* that $Q_r = 0$ with $\varepsilon_r \neq 0$. If $\varepsilon_r = 0$, $\overline{S_r S_j} = 0$ for all $1 \le j \le M$ which leads directly *by definition* to $Q_r = 0$. For $\varepsilon_r = 0$, the refractory emissive power E_r *never enters the zoning calculations.* For the special case of $K = 0$ and $M_r = 1$, a single (lumped) refractory, with $Q_r = 0$ and $\varepsilon_r \neq 0$, $\overline{S_r S_j} \neq 0$ and the refractory emissive power may be calculated from Eq. (5-120*a*) as a weighted sum of all *other known blackbody emissive powers* which

characterize the enclosure, i.e.,

$$E_r = \frac{\sum_{j=1}^{M_S} \overline{S_r S_j} \cdot E_j}{\sum_{j=1}^{M_S} \overline{S_r S_j}} \qquad \text{with } j \neq r \tag{5-121}$$

Equation (5-121) specifically *includes* those zones which may not have a *direct* view of the refractory. When $Q_r = 0$, the refractory surface is said to be in **radiative equilibrium** with the entire enclosure. Equation (5-121) is indeterminate if $\varepsilon_r = 0$. If $\varepsilon_r = 0$, E_r does indeed exist and may be evaluated with use of the statement $E_r = H_r = W_r$. It transpires, however, that E_r is *independent of* ε_r *for all* $0 \le \varepsilon_r \le 1$. Moreover, since $W_r = H_r$ when $Q_r = 0$, for all $0 \le \varepsilon_r \le 1$, the value specified for ε_r is irrelevant to radiative transfer in the *entire enclosure*. In particular it follows that if $Q_r = 0$, then the *vectors* **W, H,** and **Q** *for the entire enclosure* are also independent of all $0 \le \varepsilon_r \le 1.0$. A surface zone for which $\varepsilon_i = 0$ is termed a **perfect diffuse mirror.** A perfect diffuse mirror is thus also an adiabatic surface zone. The matrix method automatically deals with *all* options for flux and adiabatic refractory surfaces.

The Limiting Case of a Transparent Medium For the special case of a transparent medium, $K = 0$, many practical engineering applications can be modeled with the zone method. These include combustion-fired muffle furnaces and electrical resistance furnaces. When $K \to 0$, $\overline{\mathbf{sg}} \to \mathbf{0}$ and $\overline{\mathbf{SG}} \to \mathbf{0}$. Equations (5-118) through (5-119) then reduce to three simple matrix relations

$$\mathbf{Q} = \varepsilon\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{E} - \overline{\mathbf{SS}} \cdot \mathbf{E} \tag{5-122a}$$

$$\overline{\mathbf{SS}} = \varepsilon\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{R} \cdot \overline{\mathbf{ss}} \cdot \varepsilon\mathbf{I} \tag{5-122b}$$

with again

$$\mathbf{R} \equiv [\mathbf{AI} - \overline{\mathbf{ss}} \cdot \rho\mathbf{I}]^{-1} \tag{5-122c}$$

The radiant surface flux vector **Q,** as computed from Eq. (5-122*a*), *always* satisfies the (scalar) conservation condition $\mathbf{1}_M^T \cdot \mathbf{Q} = \mathbf{0}$ or $\sum_{i=1}^{M} Q_i = 0$, which is a statement of the overall *radiant* energy balance. The matrix conservation relations also simplify to

$$\mathbf{AI} \cdot \mathbf{1}_M = \overline{\mathbf{ss}} \cdot \mathbf{1}_M \tag{5-123a}$$

$$\varepsilon\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{1}_M = \overline{\mathbf{SS}} \cdot \mathbf{1}_M \tag{5-123b}$$

And the $M \times M$ arrays for *all* the direct and total view factors can be readily computed from

$$\mathbf{F} = \mathbf{AI}^{-1} \cdot \overline{\mathbf{ss}} \tag{5-124a}$$

and

$$\mathcal{F} = \mathbf{AI}^{-1} \cdot \overline{\mathbf{SS}} \tag{5-124b}$$

where the following matrix conservation relations must also be satisfied,

$$\mathbf{F} \cdot \mathbf{1}_M = \mathbf{1}_M \tag{5-125a}$$

and

$$\mathcal{F} \cdot \mathbf{1}_M = \varepsilon\mathbf{I} \cdot \mathbf{1}_M \tag{5-125b}$$

The Two-Zone Enclosure Figure 5-18 depicts four simple enclosure geometries which are particularly useful for engineering calculations characterized by only *two* surface zones. For $M = 2$, the reflectivity matrix **R** is readily evaluated in *closed form* since an explicit algebraic inversion formula is available for a 2×2 matrix. In this case knowledge of only $\Sigma = 1$ direct exchange area is required. Direct evaluation of Eqs. (5-122) then leads to

$$\overline{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1 A_1 - \overline{S_1 S_2} & \overline{S_1 S_2} \\ \overline{S_1 S_2} & \varepsilon_2 A_2 - \overline{S_1 S_2} \end{bmatrix} \tag{5-126}$$

where

$$\overline{S_1 S_2} = \frac{1}{\left(\dfrac{1}{\overline{s_1 s_2}} + \dfrac{\rho_1}{\varepsilon_1 A_1} + \dfrac{\rho_2}{\varepsilon_2 A_2} \right)} \tag{5-127}$$

Equation (5-127) is of general utility for any two-zone system for which $\varepsilon_i \neq 0$.

The total exchange areas for the four geometries shown in Fig. 5-18 follow directly from Eqs. (5-126) and (5-127).

1. A planar surface A_1 completely surrounded by a second surface $A_2 > A_1$. Here $F_{1,1} = 0$, $F_{1,2} = 1$, and $\overline{s_1 s_2} = A_1$, resulting in

$$\overline{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1 \rho_2 A_1^2 + \varepsilon_2 \rho_1 A_1 A_2 & \varepsilon_1 \varepsilon_2 A_1 A_2 \\ \varepsilon_1 \varepsilon_2 A_1 A_2 & \varepsilon_2 A_2^2 + \varepsilon_1 (\rho_2 - \varepsilon_2) A_1 A_2 \end{bmatrix} / [\varepsilon_1 \rho_2 A_1 + \varepsilon_2 A_2]$$

and in particular

$$\overline{S_1 S_2} = \frac{A_1}{1/\varepsilon_1 + (A_1/A_2)(\rho_2/\varepsilon_2)} \tag{5-127a}$$

In the limiting case, where A_1 has no negative curvature and is completely surrounded by a very much larger surface A_2 such that $A_1 \ll A_2$, Eq. (5-127*a*) leads to the even simpler result that $\overline{S_1 S_2} = \varepsilon_1 \cdot A_1$.

2. Two parallel plates of equal area which are large compared to their distance of separation (infinite parallel plates). Case 2 is a limiting form of case 1 with $A_1 = A_2$. Algebraic manipulation then results in

$$\overline{\mathbf{SS}} = \begin{bmatrix} (\varepsilon_1 + \varepsilon_2 - 2\varepsilon_1\varepsilon_2) \cdot A_1 & \varepsilon_1 \varepsilon_2 A_1 \\ \varepsilon_1 \varepsilon_2 A_1 & (\varepsilon_1 + \varepsilon_2 - 2\varepsilon_1\varepsilon_2) A_1 \end{bmatrix} / [\varepsilon_1 + \varepsilon_2 - \varepsilon_1\varepsilon_2]$$

and in particular

$$\overline{S_1 S_2} = \frac{A_1}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} \tag{5-127b}$$

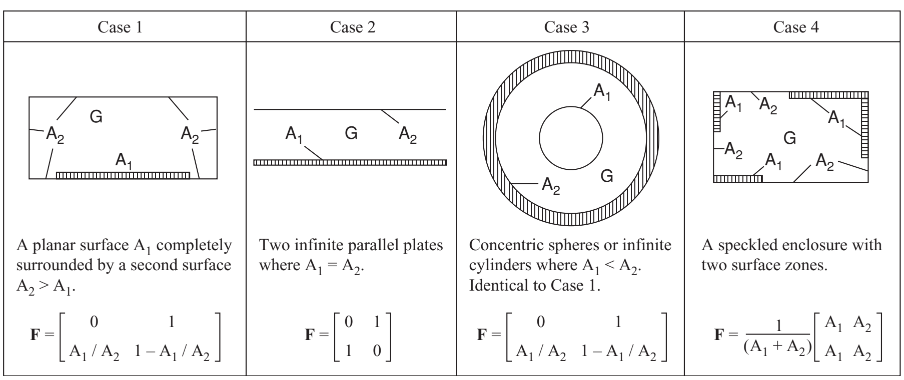

FIG. 5-18 Four enclosure geometries characterized by two surface zones and one volume zone. (Marks' Standard Handbook for Mechanical Engineers, *McGraw-Hill, New York, 1999, p. 4-73, Table 4.3.5.*)

3. Concentric spheres or cylinders where $A_2 > A_1$. Case 3 is mathematically identical to case 1.

4. A **speckled enclosure** with two surface zones. Here $\mathbf{F} = \frac{1}{A_1 + A_2}\begin{bmatrix} A_1 & A_2 \\ A_1 & A_2 \end{bmatrix}$ such that $\overline{\mathbf{ss}} = \frac{1}{A_1 + A_2}\begin{bmatrix} A_1^2 & A_1A_2 \\ A_1A_2 & A_2 \end{bmatrix}$ and Eqs. (5-126) and (5-127) then produce

$$\overline{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1^2 A_1^2 & \varepsilon_1\varepsilon_2 A_1 A_2 \\ \varepsilon_1\varepsilon_2 A_1 A_2 & \varepsilon_2^2 A_2^2 \end{bmatrix} / [\varepsilon_1 A_1 + \varepsilon_2 A_2]$$

with the particular result

$$\overline{S_1S_2} = \frac{1}{1/(\varepsilon_1 A_1) + 1/(\varepsilon_2 A_2)} \tag{5-127c}$$

Physically, a two-zone speckled enclosure is characterized by the fact that the view factor from any point on the enclosure surface to the sink zone is identical to that from any other point on the bounding surface. This is only possible when the two zones are "intimately mixed." The seemingly simplistic concept of a speckled enclosure provides a surprisingly useful *default option* in engineering calculations when the *actual* enclosure geometries are quite complex.

Multizone Enclosures [M ≥ 3] Again assume $K = 0$. The major numerical effort involved in implementation of the zone method is the evaluation of the inverse reflection matrix **R**. For $M = 3$, explicit closed-form algebraic formulas *do indeed exist* for the nine scalar elements of the inverse of any arbitrary nonsingular matrix. These formulas are so algebraically complex, however, that it proves impractical to present universal closed-form expressions for the total exchange areas, as has been done for the case $M = 2$. Fortunately, many practical furnace configurations can be idealized with zoning such that only relatively simple *hand calculation procedures are required*. Here the enclosure is modeled with only $M = 3$ surface zones, e.g., a single source, a single sink, and a lumped adiabatic refractory zone. This approach is sometimes termed the **SSR model.** The SSR model assumes that all adiabatic refractory surfaces are *perfect diffuse mirrors*. To implement the SSR procedure, it is necessary to develop *specialized algebraic formulas* and to define a *third black view factor* $\overline{F}_{i,j}$ with an *overbar* as follows.

Refractory Augmented Black View Factors $\overline{F}_{i,j}$ Let $M = M_r + M_b$, where M_b is the number of black surface zones and M_r is the number of adiabatic refractory zones. Assume $\varepsilon_r = 0$ or $\rho_r = 1$ or, equivalently, that all adiabatic refractory surfaces are *perfect diffuse mirrors.* The view factor $\overline{F}_{i,j}$ is then defined as the **refractory augmented black view factor**, i.e., the direct view factor between *any two* black source-sink zones, A_i **and** A_j, *with full allowance for reflections from all intervening refractory surfaces*. The quantity $\overline{F}_{i,j}$ shall be referred to as ***F*-bar,** for expediency.

Consider the special situation where $M_b = 2$, with any number of refractory zones $M_r \geq 1$. By use of appropriate row and column reduction of the reflectivity matrix **R,** an especially useful relation can be derived that allows computation of the conventional total exchange area $\overline{S_iS_j}$ from the *corresponding refractory augmented black view factor* $\overline{F}_{i,j}$

$$\overline{S_1S_2} = \frac{1}{\left(\frac{\rho_1}{\varepsilon_1 A_1} + \frac{\rho_2}{\varepsilon_2 A_2} + \frac{1}{A_1\overline{F}_{1,2}}\right)} \tag{5-128a}$$

or

$$\mathcal{F}_{1,2} = \frac{1}{\left(\frac{\rho_1}{\varepsilon_1} + \left(\frac{A_1}{A_2}\right)\cdot\frac{\rho_2}{\varepsilon_2} + \frac{1}{\overline{F}_{1,2}}\right)} \tag{5-128b}$$

where $\varepsilon_i \neq 0$. Notice that Eq. (5-128*a*) appears *deceptively similar* to Eq. (5-127). Collectively, Eqs. (5-128) along with various formulas to compute $\overline{F}_{i,j}$ (*F*-bar) are sometimes called the three-zone source/sink/refractory **SSR model.**

The following formulas permit the calculation of $\overline{F}_{i,j}$ from requisite *direct* exchange areas. For the special case where the enclosure is divided into *any number of* black source-sink zones, $M_b \geq 2$, and the remainder of the enclosure is lumped together into a single refractory zone ($M_r = 1$) with total area A_r and uniform average temperature T_r, then the direct refractory augmented exchange area for the black zone pairs is given by

$$A_i\overline{F}_{i,j} = A_j\overline{F}_{j,i} = \overline{s_is_j} + \frac{\overline{s_is_r}\cdot\overline{s_rs_j}}{A_r - \overline{s_rs_r}} \qquad \text{for } 1 \leq i,j \leq M_b \tag{5-129}$$

For the special case $M_b = 2$ and $M_r = 1$, Eq. (5-129) then simplifies to

$$A_1\overline{F}_{1,2} = A_2\overline{F}_{2,1} = \overline{s_1s_2} + \frac{1}{1/\overline{s_1s_r} + 1/\overline{s_2s_r}} \tag{5-130}$$

and if $\overline{s_1s_1} = \overline{s_2s_2} = 0$, Eq. (5-130) further reduces to

$$A_1\overline{F}_{1,2} = \overline{s_1s_2} + \frac{1}{1/(A_1 - \overline{s_1s_2}) + 1/(A_2 - \overline{s_2s_1})} = \frac{A_1A_2 - (\overline{s_1s_2})^2}{A_1 + A_2 - 2\overline{s_1s_2}} \tag{5-131}$$

which necessitates the evaluation of only one direct exchange area. Let the M_r refractory zones be numbered *last*. Then the $M_b \times M_b$ *array* of refractory augmented direct exchange areas $[A_i\overline{F}_{i,j}]$ is symmetric and satisfies and the conservation relation

$$[A_i\cdot\overline{F}_{i,j}]\cdot\mathbf{1}_{M_b} = \mathbf{AI}\cdot\mathbf{1}_{M_b} \tag{5-132a}$$

with

$$\overline{\mathbf{F}}\cdot\mathbf{1}_{M_b} = \mathbf{1}_{M_b} \tag{5-132b}$$

Temporarily denote $\overline{S_1S_2}]_R$ as the value of $\overline{S_1S_2}$ computed from Eq. (5-128*a*) which assumes $\varepsilon_r = 0$. It remains to demonstrate the relationship between $\overline{S_1S_2}]_R$ and the total exchange area $\overline{S_1S_2}$ computed from the matrix method for $M = 3$ when zone 3 is an adiabatic refractory for which $Q_3 = 0$ and $\varepsilon_3 \neq 0$. Let $\Theta_i = (E_i - E_2)/(E_1 - E_2)$ denote the dimensionless emissive power where $E_1 > E_2$ such that $\Theta_1 = 1$ and $\Theta_2 = 0$. The dimensionless refractory emissive power may then be calculated from Eq. (5-121) as $\Theta_3 = \overline{S_3S_1}/[\overline{S_3S_1} + \overline{S_3S_2}]$, which when substituted into Eq. (5-122*a*) leads to $\overline{S_1S_2}]_R = \overline{S_1S_2} + \overline{S_2S_3}\cdot\Theta_3 = \overline{S_1S_2} + \overline{S_1S_3}\cdot\overline{S_3S_2}/[\overline{S_3S_1} + \overline{S_3S_2}]$. Thus $\overline{S_1S_2}]_R$ is clearly the *refractory-aided* total exchange area between zone 1 and zone 2 and *not* $\overline{S_1S_2}$ as calculated by the matrix method in general. That is, $\overline{S_1S_2}]_R$ includes not only the radiant energy originating at zone 1 and arriving at zone 2 directly and by reflection from zones 2 and 3, but also radiation originating at zone 1 that is *absorbed* by zone 3 and then wholly reemitted to zone 2; that is, $H_3 = W_3 = E_3$.

Evaluation of any total view factor $\mathcal{F}_{i,j}$ using the requisite refractory augmented black view factor $\overline{F}_{i,j}$ obviously requires that the latter be readily available and/or capable of calculation. The refractory augmented view factor $\overline{F}_{i,j}$ is documented for a few geometrically simple cases and can be calculated or approximated for others. If A_1 and A_2 are equal parallel disks, squares, or rectangles, connected by nonconducting but reradiating refractory surfaces, then $\overline{F}_{i,j}$ is given by Fig. 5-13 in curves 5 to 8. Let A_1 represent an infinite plane and A_2 represent one or two rows of infinite parallel tubes. If the only other surface is an adiabatic refractory surface located behind the tubes, $\overline{F}_{2,1}$ is then given by curve 5 or 6 of Fig. 5-15.

Experience has shown that the simple SSR model can yield quite useful results for a host of practical engineering applications without resorting to digital computation. The error due to representation of the source and sink by single zones is often small, even if the views of the enclosure from different parts of the same zone are dissimilar, provided the surface emissivities are near unity. The error is also small if the temperature variation of the refractory is small. Any degree of accuracy can, of course, be obtained via the matrix method for arbitrarily large M and N by using a digital computer. From a computational viewpoint, when $M \geq 4$, the matrix method *must be used*. The matrix method must also be used for finer-scale calculations such as more detailed wall *temperature and flux density profiles*.

The Electrical Network Analog At each surface zone the *total* radiant flux is proportional to the difference between E_i and W_i, as indicated by the equation $Q_i = (\varepsilon_i A_i \rho_i)(E_i - W_i)$. The *net* flux between zones i and j is also given by $Q_{i,j} = \overline{s_is_j}(W_i - W_j)$, where $Q_i = \sum_{j=1}^{M} Q_{i,j}$, for all $1 \leq i \leq M$, is the *total* heat flux leaving each zone. These relations

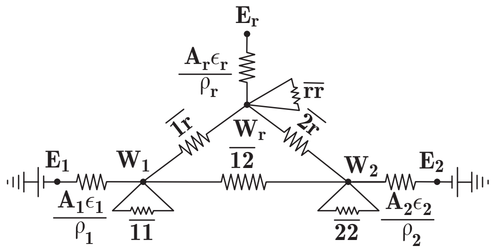

FIG. 5-19 Generalized electrical network analog for a three-zone enclosure. Here A_1 and A_2 are gray surfaces and A_r is a radiatively adiabatic surface. (*Hottel, H. C., and A. F. Sarofim*, Radiative Transfer, *McGraw-Hill, New York, 1967, p. 91.*)

suggest a *visual* electrical analog in which E_i and W_i are analogous to voltage potentials. The quantities $\varepsilon_i A_i/\rho_i$ and $\overline{s_i s_j}$ are analogous to conductances (reciprocal impedances), and Q_i or $Q_{i,j}$ is analogous to electric currents. Such an electrical analog has been developed by Oppenheim [Oppenheim, A. K., *Trans. ASME*, **78,** 725–735 (1956)].

Figure 5-19 illustrates a generalized electrical network analogy for a three-zone enclosure consisting of one refractory zone and two gray zones A_1 and A_2. The potential points E_i and W_i are separated by conductances $\varepsilon_i A_i/\rho_i$. The emissive powers E_1, E_2 represent potential sources or sinks, while W_1, W_2, and W_r are internal node points. In this construction the nodal point representing each surface is connected to that of every other surface it can see directly. Figure 5-19 can be used to formulate the total exchange area S_1S_2 for the SSR model virtually by inspection. The refractory zone is first characterized by a floating potential such that $E_r = W_r$. Next, the resistance for the parallel "current paths" between the internal nodes W_1 and W_2 is defined by $\dfrac{1}{A_1\overline{F}_{1,2}} \equiv \dfrac{1}{\overline{s_1s_2} + 1/(1/\overline{s_1s_r} + 1/\overline{s_2s_r})}$ which is identical to Eq. (5-130). Finally, the overall impedance between the source E_1 and the sink E_2 is represented simply by three resistors in series and is thus given by

$$\frac{1}{\overline{S_1S_2}} = \frac{\rho_1}{\varepsilon_1 A_1} + \frac{1}{A_1\overline{F}_{1,2}} + \frac{\rho_2}{\varepsilon_2 A_2}$$

or

$$\overline{S_1S_2} = \frac{1}{\dfrac{\rho_1}{\varepsilon_1 A_1} + \dfrac{\rho_2}{\varepsilon_2 A_2} + \dfrac{1}{A_1\overline{F}_{1,2}}} \qquad (5\text{-}133)$$

This result is identically that for the SSR model as obtained previously in Eq. (5-128*a*). This equation is also valid for $M_r \geq 1$ as long as $M_b = 2$. The electrical network analog methodology can be generalized for enclosures having $M > 3$.

Some Examples from Furnace Design The theory of the past several subsections is best understood in the context of two engineering examples involving furnace modeling. The engineering idealization of the **equivalent gray plane concept** is introduced first. Figure 5-20 depicts a common furnace configuration in which the heating source is two refractory-backed, internally fired tube banks. Clearly the overall geometry for even this common furnace configuration is too complex to be modeled in an expeditious manner by anything other than *a simple engineering idealization*. Thus the furnace shown in Fig. 5-20 is modeled in Example 10, by *partitioning* the entire enclosure into two subordinate furnace compartments. The approach first defines an imaginary gray plane A_2, located on the inward-facing side of the tube assemblies. Second, the total exchange area between the tubes to this *equivalent* gray plane is calculated, making full allowance for the reflection from the refractory tube backing. The plane-to-tube view factor is then *defined* to be the emissivity of the required equivalent gray plane whose temperature is further assumed to be that of the tubes. This procedure guarantees continuity of the radiant flux *into* the interior radiant portion of the furnace arising from a moderately complicated *external* source.

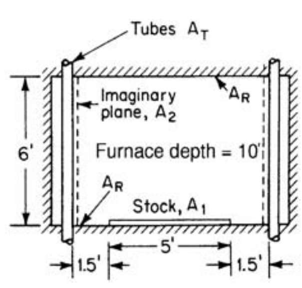

FIG. 5-20 Furnace chamber cross section. To convert feet to meters, multiply by 0.3048.

Example 9 demonstrates classical zoning calculations for radiation pyrometry in furnace applications. Example 10 is a classical furnace design calculation via zoning an enclosure with a *diathermanous* atmosphere and $M = 4$. The latter calculation can only be addressed with the matrix method. The results of Example 10 demonstrate the relative insensitivity of zoning to $M > 3$ and the engineering utility of the SSR model.

Example 9: Radiation Pyrometry A long tunnel furnace is heated by electrical resistance coils embedded in the ceiling. The stock travels on a floor-mounted conveyer belt and has an estimated emissivity of 0.7. The sidewalls are unheated refractories with emissivity 0.55, and the ceiling emissivity is 0.8. The furnace cross section is rectangular with height 1 m and width 2 m. A total radiation pyrometer is sighted on the walls and indicates the following apparent temperatures: ceiling, 1340°C; sidewall readings average about 1145°C; and the load indicates about 900°C. (*a*) What are the true temperatures of the furnace walls and stock? (*b*) What is the net heat flux at each surface? (*c*) How do the matrix method and SSR models compare?

Three-zone model, M = 3:

Zone 1: Source (top)

Zone 2: Sink (bottom)

Zone 3: Refractory (lumped sides)

Physical constants:

$$T_0 \equiv 273.15\ \text{K} \qquad \sigma \equiv 5.670400 \times 10^{-8}\,\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}$$

Enclosure input parameters:

$$H_e := 1\ \text{m} \quad W_e := 2\ \text{m} \quad L_e := 1\ \text{m} \quad A_1 := W_e\cdot L_e \quad A_2 := A_1 \quad A_3 := 2H_e\cdot L_e$$

$$\varepsilon_1 := .8 \quad \varepsilon_2 := .7 \quad \varepsilon_3 := .55 \quad \rho_1 := 1-\varepsilon_1 \quad \rho_2 := 1-\varepsilon_2 \quad \rho_3 := 1-\varepsilon_3$$

$$\mathbf{AI} := \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix} \quad \boldsymbol{\varepsilon}\mathbf{I} := \begin{bmatrix} \varepsilon_1 & 0 & 0 \\ 0 & \varepsilon_2 & 0 \\ 0 & 0 & \varepsilon_3 \end{bmatrix} \quad \boldsymbol{\rho}\mathbf{I} := \begin{bmatrix} \rho_1 & 0 & 0 \\ 0 & \rho_2 & 0 \\ 0 & 0 & \rho_3 \end{bmatrix}$$

$$\mathbf{AI} := \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix}\text{m}^2 \quad \boldsymbol{\varepsilon}\mathbf{I} := \begin{bmatrix} 0.8 & 0 & 0 \\ 0 & 0.7 & 0 \\ 0 & 0 & 0.55 \end{bmatrix} \quad \boldsymbol{\rho}\mathbf{I} := \begin{bmatrix} 0.2 & 0 & 0 \\ 0 & 0.3 & 0 \\ 0 & 0 & 0.45 \end{bmatrix}$$

Compute direct exchange areas by using crossed strings (Σ = 3):

$$ss_{11} := 0 \quad ss_{22} := 0 \quad ss_{33} := 2\left(\sqrt{H_e^2 + W_e^2} - W_e\right)L_e \quad ss_{33} := 0.4721\ \text{m}^2$$

From symmetry and conservation, there are three linear simultaneous results for the off-diagonal elements of **ss:**

$$\begin{bmatrix} \overline{12} \\ \overline{13} \\ \overline{23} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}^{-1} \begin{bmatrix} A_1 - \overline{11} \\ A_2 - \overline{22} \\ A_3 - \overline{33} \end{bmatrix} = \frac{1}{2}\begin{bmatrix} 1 & 1 & -1 \\ 1 & -1 & 1 \\ -1 & 1 & 1 \end{bmatrix}$$

$$\times \begin{bmatrix} A_1 - \overline{11} \\ A_2 - \overline{22} \\ A_3 - \overline{33} \end{bmatrix} = \frac{1}{2}\begin{bmatrix} +A_1 + A_2 - A_3 - \overline{11} - \overline{22} + \overline{33} \\ +A_1 - A_2 + A_3 - \overline{11} + \overline{22} - \overline{33} \\ -A_1 + A_2 + A_3 + \overline{11} - \overline{22} - \overline{33} \end{bmatrix}$$

Thus

$$ss_{12} := 0.5\,(A_1 + A_2 - A_3 + ss_{33})$$
$$ss_{13} := 0.5\,(A_1 - A_2 + A_3 - ss_{33}) \quad ss_{23} := 0.5\,(-A_1 + A_2 + A_3 - ss_{33})$$

$$\overline{\overline{\mathbf{ss}}} := \begin{bmatrix} ss_{11} & ss_{12} & ss_{13} \\ ss_{12} & ss_{22} & ss_{23} \\ ss_{13} & ss_{23} & ss_{33} \end{bmatrix} \quad \overline{\overline{\mathbf{ss}}} := \begin{bmatrix} 0 & 1.2361 & 0.7639 \\ 1.2361 & 0 & 0.7639 \\ 0.7639 & 0.7639 & 0.4721 \end{bmatrix}\text{m}^2 \quad (\text{AI} - \overline{\overline{\mathbf{ss}}})\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\text{m}^2$$

Compute radiosities W from pyrometer temperature readings:

$$\mathbf{T_{wc}} := \begin{bmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{bmatrix} C \quad \mathbf{W} := \sigma\left(\mathbf{T_{wc}} \cdot \frac{K}{C} + T_0\right)^4 \quad \mathbf{W} := \begin{bmatrix} 384.0 \\ 107.4 \\ 229.4 \end{bmatrix} \frac{kW}{m^2}$$

Matrix wall flux density relations and heat flux calculations based on W:

$$\mathbf{H} := \mathbf{AI^{-1}ss{\cdot}W} \qquad \mathbf{Q} := \mathbf{AI(W - H)} \qquad \mathbf{E} := \mathbf{(\varepsilon I{\cdot}AI)^{-1}{\cdot}Q + H}$$

$$\mathbf{H} := \begin{bmatrix} 154.0 \\ 324.9 \\ 241.8 \end{bmatrix} \frac{kW}{m^2} \quad \mathbf{Q} := \begin{bmatrix} 460.0 \\ -435.0 \\ -25.0 \end{bmatrix} kW \quad \mathbf{E} := \begin{bmatrix} 441.5 \\ 14.2 \\ 219.1 \end{bmatrix} \frac{kW}{m^2}$$

The sidewalls act as near-adiabatic surfaces since the heat loss through each sidewall is only about 2.7 percent of the total heat flux originating at the source.

Actual temperatures versus pyrometer readings:

$$\mathbf{T} := \left[\left(\frac{E}{\sigma}\right)^{0.25} - T_0\right]\frac{C}{K} \quad \mathbf{T} = \begin{bmatrix} 1397.3 \\ 434.1 \\ 1128.9 \end{bmatrix} C \quad \text{versus} \quad \mathbf{T_{wc}} = \begin{bmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{bmatrix} C$$

Compare SSR model versus matrix method [use Eqs. (5-128*a*) and (5-130)]: From Eq. (5-130)

$$\text{ssbar}_{12} := ss_{1,2} + \cfrac{1}{\cfrac{1}{ss_{1,3}} + \cfrac{1}{ss_{2,3}}} \qquad \text{ssbar}_{12} = 1.6180\ m^2$$

And from Eq. (5-128*a*)

$$\text{SSR}_{12} := \cfrac{1}{\cfrac{\rho_1}{\varepsilon_1{\cdot}A_1} + \cfrac{\rho_2}{\varepsilon_2{\cdot}A_2} + \cfrac{1}{\text{ssbar}_{12}}} \qquad \text{SSR}_{12} = 1.0446\ m^2$$

With the numerical result $\quad Q_{12} := \text{SSR}_{12}(E_1 - E_2) \qquad Q_{12} = 446.3\ kW$

Thus the SSR model produces $Q_{12} = 446.3$ kW versus the measured value $Q_1 = 460.0$ kW or a discrepency of about 3.0 percent. Mathematically the SSR model assumes a value of $\varepsilon_3 = 0.0$, which precludes the sidewall heat loss of $Q_3 = -25.0$ kW. This assumption accounts for *all* of the difference between the two values. It remains to compare SSR_{12} and $\text{SS}_{1,2}$ computed by the matrix method.

Compute total exchange areas ($\varepsilon_3 = 0.55$):

$$\mathbf{R} := (\mathbf{AI} - \overline{\mathbf{ss}}{\cdot}\boldsymbol{\rho}\mathbf{I})^{-1}$$

$$\overline{\overline{\mathbf{SS}}} := \boldsymbol{\varepsilon}\mathbf{I{\cdot}AI{\cdot}R{\cdot}}\overline{\mathbf{ss}}{\cdot}\boldsymbol{\varepsilon}\mathbf{I} \quad \overline{\overline{\mathbf{SS}}} = \begin{bmatrix} 0.2948 & 0.8284 & 0.4769 \\ 0.8284 & 0.1761 & 0.3955 \\ 0.4769 & 0.3955 & 0.2277 \end{bmatrix} m^2 \quad (\boldsymbol{\varepsilon}\mathbf{I{\cdot}AI} - \overline{\overline{\mathbf{SS}}}) \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} m^2$$

Clearly SSR_{21} and $\text{SS}_{1,2}$ are unequal. But if

$$\Theta_3 := \frac{SS_{3,1}}{SS_{3,1} + SS_{3,2}}$$

define

$$\text{SSA}_{12} := SS_{1,2} + SS_{2,3}{\cdot}\Theta_3$$

and

$$\Theta_3 := 0.5466 \quad \text{SSA}_{12} = 1.0446\ m^2 \quad E_r := E_2 + (E_1 - E_2){\cdot}\Theta_3 \quad E_r = 247.8\ \frac{kW}{m^2}$$

Numerically the matrix method predicts $\text{SSA}_{12} = 1.0446$ m² for $Q_3 = 0$ and $\varepsilon_3 = 0.55$, which is identical to $\text{SSR}_{1,2}$ for the SSR model. Thus $\text{SSR}_{1,2} = \text{SSA}_{12}$ is the *refractory-aided* total exchange area between zone 1 and zone 2. The SSR model also predicts $E_r = 247.8$ kW/m² versus the experimental value $E_3 = 219.1$ kW/m² (1172.6C vs. 1128.9C), which is also a consequence of the actual 25.0-kW refractory heat loss.

(This example was developed as a MATHCAD 14® worksheet. Mathcad is a registered trademark of Parametric Technology Corporation.)

Example 10: Furnace Simulation via Zoning The furnace chamber depicted in Fig. 5-20 is heated by combustion gases passing through 20 vertical radiant tubes which are backed by refractory sidewalls. The tubes have an outside diameter of D = 5 in (12.7 cm) mounted on C = 12 in (4.72 cm) centers and a gray body emissivity of 0.8. The interior (radiant) portion of the furnace is a 6 × 8 × 10 ft rectangular parallelepiped with a total surface area of 376 ft² (34.932 m²). A 50-ft² (4.645-m²) sink is positioned centrally on the floor of the furnace. The tube and sink temperatures are measured with embedded thermocouples as 1500 and 1200°F, respectively. The gray refractory emissivity may be taken as 0.5. While all *other* refractories are assumed to be radiatively adiabatic, the roof of the furnace is estimated to lose heat to the surroundings with a *flux density* (W/m²) equal to 5 percent of the source and sink emissive power difference. An estimate of the radiant flux arriving at the sink is required, as well as estimates for the roof and average refractory temperatures in consideration of refractory service life.

Part (a): Equivalent Gray Plane Emissivity Algebraically compute the equivalent gray plane emissivity for the refractory-backed tube bank idealized by the imaginary plane A_2, depicted in Fig. 5-15.

Solution: Let zone 1 represent *one* tube and zone 2 represent the *effective* plane 2, that is, the *unit cell* for the tube bank. Thus $A_1 = \pi D$ and $A_2 = C$ are the corresponding zone areas, respectively (per unit vertical dimension). This notation is consistent with Example 3. Also put $\varepsilon_1 = 0.8$ with $\varepsilon_2 = 1.0$ and define R = C/D = 12/5 = 2.4. The gray plane effective emissivity is then calculated as the total view factor for the effective plane to tubes, that is, $\mathcal{F}_{2,1} \equiv \underline{\underline{\varepsilon}}_2$. For R = 2.4, Fig. 5-15, curve 5, yields the refractory augmented view factor $\overline{F}_{2,1} \approx 0.81$. Then $\mathcal{F}_{2,1}$ is calculated from Eq. (5-128*b*) as $\mathcal{F}_{2,1} = \dfrac{1}{0/1 + (2.4/\pi){\cdot}0.2/0.8 + 1/0.81} \approx 0.702$.

A more accurate value is obtained via the matrix method as $\mathcal{F}_{2,1} = 0.70295$.

Part (b): Radiant Furnace Chamber with Heat Loss
Four-zone model, M = 4: Use matrix method.
Zone 1: Sink (floor)
Zone 2: Source (lumped sides)
Zone 3: Refractory (roof)
Zone 4: Refractory (ends and floor strips)

Physical constants:

$$T_0 \equiv 273.15\ K \quad \sigma \equiv 5.6704 \times 10^{-8} \frac{W}{m^2{\cdot}K^4}$$

Enclosure input parameters:

$A_1 := 50\ ft^2 \quad A_2 := 120\ ft^2 \quad A_3 := 80\ ft^2 \quad A_4 := 126\ ft^2 \quad D := 5\ in \quad H := 6\ ft$

$\varepsilon_1 := .9 \quad \varepsilon_2 := .70295 \quad \varepsilon_3 := .5 \quad \varepsilon_4 := .5 \quad \mathbf{I_4} := \text{identity}(4)$

$$\boldsymbol{\varepsilon}\mathbf{I} = \begin{bmatrix} 0.9 & 0 & 0 & 0 \\ 0 & 0.7029 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0 & 0.5 \end{bmatrix} \quad \boldsymbol{\rho}\mathbf{I} := \mathbf{I_4} - \boldsymbol{\varepsilon}\mathbf{I} \quad \boldsymbol{\rho}\mathbf{I} = \begin{bmatrix} 0.1 & 0 & 0 & 0 \\ 0 & 0.2971 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0 & 0.5 \end{bmatrix}$$

Compute direct exchange areas: There are $\sum = 6$ unique direct exchange areas. These are obtained from Eqs. (5-114) and view factor algebra. The final array of direct exchange areas is:

$$\overline{\mathbf{ss}} = \begin{bmatrix} 0 & 1.559 & 1.575 & 1.511 \\ 1.559 & 2.078 & 2.839 & 4.673 \\ 1.575 & 2.839 & 0 & 3.018 \\ 1.511 & 4.673 & 3.018 & 2.503 \end{bmatrix} m^2 \quad \mathbf{AI} = \begin{bmatrix} 4.645 & 0 & 0 & 0 \\ 0 & 11.148 & 0 & 0 \\ 0 & 0 & 7.432 & 0 \\ 0 & 0 & 0 & 11.706 \end{bmatrix} m^2$$

Compute total exchange areas:

$$\mathbf{R} := (\mathbf{AI} - \overline{\mathbf{ss}}{\cdot}\boldsymbol{\rho}\mathbf{I})^{-1}$$

$$\overline{\overline{\mathbf{SS}}} := \boldsymbol{\varepsilon}\mathbf{I{\cdot}AI{\cdot}R{\cdot}ss{\cdot}}\boldsymbol{\varepsilon}\mathbf{I} \qquad \overline{\overline{\mathbf{SS}}} = \begin{bmatrix} 0.405 & 1.669 & 0.955 & 1.152 \\ 1.669 & 2.272 & 1.465 & 2.431 \\ 0.955 & 1.465 & 0.234 & 1.063 \\ 1.152 & 2.431 & 1.063 & 1.207 \end{bmatrix} m^2$$

Check matrix conservation via row-sums:

$$(\mathbf{AI} - \overline{\mathbf{ss}}) \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} m^2 \quad (\boldsymbol{\varepsilon}\mathbf{I{\cdot}AI} - \overline{\overline{\mathbf{SS}}}) \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} m^2$$

Emissive power and wall flux input data:

$$\mathbf{T_F} := \begin{bmatrix} 1200 \\ 1500 \\ 32 \\ 32 \end{bmatrix} F \qquad \mathbf{T} := \frac{5}{9}(\mathbf{T_F} - 32\ F)\frac{C}{F} \qquad \mathbf{E} := \sigma\left(\mathbf{T}{\cdot}\frac{K}{C} + T_0\right)^4$$

$$\mathbf{T} = \begin{bmatrix} 648.9 \\ 815.6 \\ 0.0 \\ 0.0 \end{bmatrix} C \qquad \mathbf{E} = \begin{bmatrix} 40.98 \\ 79.66 \\ 0.32 \\ 0.32 \end{bmatrix} \frac{kW}{m^2}$$

$$Q_3 := -0.05{\cdot}A_3(E_2 - E_1) \qquad Q_3 = -14.37\ kW \qquad Q_4 := 0$$

Compute refractory emissive powers from known flux inputs Q_3 and Q_4 using partitioned matrix equations [Eq. (5-120b)]:

$$\mathbf{E_R} := \begin{bmatrix} \varepsilon_3 \cdot A_3 - SS_{3,3} & -SS_{3,4} \\ -SS_{4,3} & \varepsilon_4 \cdot A_4 - SS_{4,4} \end{bmatrix}^{-1} \cdot \begin{bmatrix} Q_3 + SS_{3,1} \cdot E_1 + SS_{3,2} \cdot E_2 \\ Q_4 + SS_{4,1} \cdot E_1 + SS_{4,2} \cdot E_2 \end{bmatrix}$$

$$\mathbf{E_R} = \begin{bmatrix} 60.68 \\ 65.73 \end{bmatrix} \frac{kW}{m^2} \qquad \mathbf{E} := \begin{bmatrix} E_1 \\ E_2 \\ E_{R_1} \\ E_{R_2} \end{bmatrix} \qquad \mathbf{E} = \begin{bmatrix} 40.98 \\ 79.66 \\ 60.68 \\ 65.73 \end{bmatrix} \frac{kW}{m^2}$$

Compute flux values and final zone temperatures:

$$\mathbf{Q} := \varepsilon \mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{E} - \overline{\mathbf{SS}} \cdot \mathbf{E} \qquad \mathbf{T} := \left[\left(\frac{\mathbf{E}}{\sigma} \right)^{0.25} - T_0 \right] \frac{C}{K}$$

$$\mathbf{Q} = \begin{bmatrix} -111.87 \\ 126.24 \\ -14.37 \\ 0.00 \end{bmatrix} kW \qquad \mathbf{T} = \begin{bmatrix} 648.9 \\ 815.6 \\ 743.9 \\ 764.5 \end{bmatrix} C$$

Auxiliary calculations for tube area and effective tube emissivity:

$$A_{Tubes} := 20\pi \cdot D \cdot H \qquad \varepsilon_{Tubes} := \frac{Q_2}{A_{Tubes}(E_2 - E_1)} \qquad A_{Tubes} = 14.59 \text{ m}^2 \qquad \varepsilon_{Tubes} = 0.2237$$

Notes: (1) Results for Q and T here are independent of ε_3 and ε_4 with the exception of T_3, which is indeed a function of ε_3. (2) The total surface area of the tubes is $A_{Tubes} = 14.59$ m^2. Suppose the tubes were totally surrounded by a *black* enclosure at the temperature of the sink. The hypothetical emissivity of the tubes would then be $\varepsilon_{Tubes} = 0.224$. (3) A 5 percent roof heat loss is consistent with practical measurement errors. A sensitivity test was performed with $M = 3$, 4, and 5 with and without roof heat loss. The SSR model corresponds to $M = 3$ with zero heat loss. For $M = 5$, zone 4 corresponded to the furnace ends and zone 5 corresponded to the floor strips. The results are summarized in the following table. With the exception of the temperature of the floor strips, the computed results are seen to be remarkably insensitive to M.

Effect of Zone Number M on Computed Results

	Zero roof heat loss			5 percent roof heat loss		
	$M = 3$	$M = 4$	$M = 5$	$M = 3$	$M = 4$	$M = 5$
			Temperature, °C			
T_3	765.8	762.0	762.4	756.2	743.9	744.3
T_4	NA	768.4	765.0	NA	764.5	761.1
T_5	NA	NA	780.9	NA	NA	776.7
			Heat flux, kW			
Q_1	−117.657	−117.275	−116.251	−112.601	−111.870	−110.877
Q_2	117.657	117.275	116.251	126.975	126.244	125.251
Q_3	0.000	0.000	0.000	−14.374	−14.374	−14.374
Q_4	NA	0.000	0.000	NA	0.00	0.00
Q_5	NA	NA	0.000	NA	NA	0.00

Allowance for Specular Reflection If the assumption that all surface zones are diffuse emitters and reflectors is relaxed, the zoning equations become much more complex. Here, all surface parameters become functions of the *angles of incidence and reflection* of the radiation beams at each surface. In practice, such details of reflectance and emission are seldom known. When they are, the Monte Carlo method of tracing a large number of beams emitted from random positions and in random initial directions is probably the best method of obtaining a solution. Siegel and Howell (op. cit., Chap. 10) and Modest (op. cit., Chap. 20) review the utilization of the Monte Carlo approach to a variety of radiant transfer applications. Among these is the Monte Carlo calculation of direct exchange areas for very complex geometries. Monte Carlo techniques are generally *not used* in practice for simpler engineering applications.

A simple *engineering* approach to specular reflection is the so-called **diffuse plus specular reflection model**. Here the total reflectivity $\rho_i = 1 - \varepsilon_i = \rho_{Si} + \rho_{Di}$ is represented as the sum of a *diffuse component* ρ_{Si} and a *specular component* ρ_{Di}. The method yields analytical results for a number of two surface zone geometries. In particular, the following equation is obtained for exchange between concentric spheres or infinitely long coaxial cylinders for which $A_1 < A_2$:

$$\overline{S_1S_2} = \frac{A_1}{\left(\frac{1}{\varepsilon_1} + \frac{\rho_2}{\varepsilon_2} \cdot \frac{A_1}{A_2} + \frac{\rho_{S2}}{(1 - \rho_{S2})} [1 - A_1/A_2] \right)} \tag{5-134}$$

For $\rho_{D1} = \rho_{D2} = 0$ (or equivalently $\rho_1 = \rho_{S1}$ with $\rho_2 = \rho_{S2}$), Eq. (5-134) yields the limiting case for wholly specular reflection, i.e.

Specular limit

$$\overline{S_1S_2} = \frac{A_1}{\left(\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1 \right)} \tag{5-134a}$$

which is independent of the area ratio, A_1/A_2. It is important to notice that Eq. (5-124*a*) is *similar* to Eq. (5-127*b*) but the emissivities here are defined as $\varepsilon_1 \equiv 1 - \rho_{S1}$ and $\varepsilon_2 \equiv 1 - \rho_{S2}$. When surface reflection is wholly diffuse [$\rho_{S1} = \rho_{S2} = 0$ or $\rho_1 = \rho_{D1}$ with $\rho_2 = \rho_{D2}$], Eq. (5-134) results in a formula *identical* to Eq. (5-127*a*), viz.

Diffuse limit

$$\overline{S_1S_2} = \frac{A_1}{\left[\frac{1}{\varepsilon_1} + \left(\frac{A_1}{A_2} \right) \frac{\rho_2}{\varepsilon_2} \right]} \tag{5-134b, 5-127a}$$

For the case of (infinite) parallel flat plates where $A_1 = A_2$, Eq. (5-134) leads to a general formula *similar* to Eq. (5-134*a*) but with the stipulation here that $\varepsilon_1 \equiv 1 - \rho_{D1} - \rho_{S1}$ and $\varepsilon_2 \equiv 1 - \rho_{D2} - \rho_{S2}$.

Another particularly interesting limit of Eq. (5-134) occurs when $A_2 \gg A_1$, which might represent a small sphere irradiated by an infinite surroundings which can reflect radiation originating at A_1 back to A_1. That is to say, even though $A_2 \to \infty$, the "self" total exchange area does not necessarily vanish, to wit

$$\overline{S_1S_1} = \frac{\varepsilon_1^2 \cdot \rho_{s2} \cdot A_1}{[1 - \rho_1 \cdot \rho_{s2}]} \quad \text{and} \quad \overline{S_1S_2} = \frac{\varepsilon_1(1 - \rho_{s2}) \cdot A_1}{[1 - \rho_1 \cdot \rho_{s2}]} \tag{5-134c,d}$$

which again exhibit diffuse and specular limits. The diffuse plus specular reflection model becomes significantly more complex for geometries with $M \geq 3$ where digital computation is usually required.

An Exact Solution to the Integral Equations—The Hohlraum Exact solutions of the fundamental *integral equations* for radiative transfer are available for only a few simple cases. One of these is the evaluation of the emittance from a small aperture, of area A_1, in the surface of an isothermal spherical cavity of radius R. In German, this geometry is termed a *hohlraum* or hollow space. For this special case the radiosity W is constant over the inner surface of the cavity. It then follows that the ratio W/E is given by

$$W/E = \frac{\varepsilon}{1 - \rho[1 - A_1/(4\pi R^2)]} \tag{5-135}$$

where ε and $\rho = 1 - \varepsilon$ are the diffuse emissivity and reflectivity of the interior cavity surface, respectively. The ratio W/E is the effective emittance of the aperture as sensed by an external narrow-angle receiver (radiometer) viewing the cavity interior. Assume that the cavity is constructed of a rough material whose (diffuse) emissivity is $\varepsilon = 0.5$. As a point of reference, if the cavity is to simulate a blackbody emitter to better than 98 percent of an ideal theoretical blackbody, Eq. (5-135) then predicts that the ratio of the aperture to sphere areas $A_1/(4\pi R^2)$ must be less than 2 percent. Equation (5-135) has practical utility in the experimental design of calibration standards for laboratory radiometers.

RADIATION FROM GASES AND SUSPENDED PARTICULATE MATTER

Introduction Flame radiation originates as a result of emission from water vapor and carbon dioxide in the hot gaseous combustion

products and from the presence of particulate matter. The latter includes emission from burning of microscopic and submicroscopic soot particles, and from large suspended particles of coal, coke, or ash. Thermal radiation owing to the presence of water vapor and carbon dioxide is not visible. The characteristic blue color of clean natural gas flames is due to chemiluminescence of the excited intermediates in the flame which contribute negligibly to the radiation from combustion products.

Gas Emissivities Radiant transfer in a gaseous medium is characterized by three quantities; the gas emissivity, gas absorptivity, and gas transmissivity. Gas emissivity refers to radiation originating within a gas volume which is incident on some reference surface. Gas absorptivity and transmissivity, however, refer to the absorption and transmission of radiation from some *external* surface radiation source characterized by some radiation temperature T_1. The sum of the gas absorptivity and transmissivity must, by definition, be unity. Gas absorptivity may be calculated from an appropriate gas emissivity. The gas emissivity is a function only of the gas temperature T_g while the absorptivity and transmissivity are functions of *both* T_g and T_1.

The **standard hemispherical monochromatic gas emissivity** is defined as the direct volume-to-surface exchange area for a hemispherical gas volume to an infinitesimal area element located at the center of the planar base. Consider monochromatic transfer in a *black* hemispherical enclosure of radius R that confines an isothermal volume of gas at temperature T_g. The temperature of the bounding surfaces is T_1. Let A_2 denote the area of the finite hemispherical surface and dA_1 denote an infinitesimal element of area located at the center of the planar base. The (dimensionless) monochromatic direct exchange area for exchange between the finite hemispherical surface A_2 and dA_1 then follows from direct integration of Eq. (5-116*a*) as

$$\frac{\partial(\overline{s_1 s_2})_\lambda}{\partial A_1} = \int_{\phi_1=0}^{\pi/2} \frac{e^{-K_\lambda R}}{\pi R^2} \cos\phi_1 \, 2\pi R^2 \sin\phi_1 \, d\phi_1 = e^{-K_\lambda R} \qquad (5\text{-}136a)$$

and from conservation there results

$$\frac{\partial(\overline{s_1 g})_\lambda}{\partial A_1} = 1 - e^{-K_\lambda R} \qquad (5\text{-}136b)$$

Note that Eq. (5-136*b*) is identical to the expression for the gas emissivity for a column of path length R. In Eqs. (5-136) the gas absorption coefficient is a function of gas temperature, composition, and wavelength, that is, $K_\lambda = K_\lambda(T,\lambda)$. The net monochromatic radiant flux density at dA_1 due to irradiation from the gas volume is then given by

$$q_{1g,\lambda} = \frac{\partial(\overline{s_1 g})_\lambda}{\partial A_1}(E_{1,\lambda} - E_{g,\lambda}) \equiv \alpha_{g1,\lambda} E_{1,\lambda} - \varepsilon_{g,\lambda} E_{g,\lambda} \qquad (5\text{-}137)$$

In Eq. (5-137), $\varepsilon_{g,\lambda}(T,\lambda) = 1 - \exp(-K_\lambda R)$ is defined as the monochromatic or *spectral gas emissivity* and $\alpha_{g,\lambda}(T,\lambda) = \varepsilon_{g,\lambda}(T,\lambda)$.

If Eq. (5-137) is integrated with respect to wavelength over the entire EM spectrum, an expression for the *total* flux density is obtained

$$q_{1,g} = \alpha_{g,1} E_1 - \varepsilon_g E_g \qquad (5\text{-}138)$$

where
$$\varepsilon_g(T_g) = \int_{\lambda=0}^{\infty} \varepsilon_\lambda(T_g,\lambda) \cdot \frac{E_{b,\lambda}(T_g,\lambda)}{E_b(T_g)} \, d\lambda \qquad (5\text{-}138a)$$

and
$$\alpha_{g,1}(T_1,T_g) = \int_{\lambda=0}^{\infty} \alpha_{g,\lambda}(T_g,\lambda) \cdot \frac{E_{b,\lambda}(T_1,\lambda)}{E_b(T_1)} \, d\lambda \qquad (5\text{-}138b)$$

define the *total* gas emissivity and absorptivity, respectively. The notation used here is analogous to that used for surface emissivity and absorptivity as previously defined. For a *real* gas $\varepsilon_g = \alpha_{g,1}$ only if $T_1 = T_g$, while for a *gray* gas mass of arbitrarily shaped volume $\varepsilon_g = \alpha_{g,1} = \partial(\overline{s_1 g})/\partial A_1$ is independent of temperature. Because $K_\lambda(T,\lambda)$ is also a function of the composition of the radiating species, it is necessary in what follows to define a second absorption coefficient $k_{p,\lambda}$, where $K_\lambda = k_{p,\lambda} p$. Here p is the partial pressure of the radiating species, and $k_{p,\lambda}$, with units of $(\text{atm}\cdot\text{m})^{-1}$, is referred to as the *monochromatic line absorption coefficient*.

Mean Beam Lengths It is always possible to represent the emissivity of an arbitrarily shaped volume of gray gas (and thus the corresponding direct gas-to-surface exchange area) with an equivalent sphere of radius $R = L_M$. In this context the hemispherical radius $R = L_M$ is referred to as the **mean beam length** of the arbitrary gas volume. Consider, e.g., an isothermal gas layer at temperature T_g confined by two infinite parallel plates separated by distance L. Direct integration of Eq. (5-116*a*) and use of conservation yield a closed-form expression for the requisite surface-gas direct exchange area

$$\frac{\partial(\overline{s_1 g})}{\partial A_1} = [1 - 2E_3(KL)] \qquad (5\text{-}139a)$$

where $E_n(z) = \int_{t=1}^{\infty} \frac{e^{-z \cdot t}}{t^n} \, dt$ is defined as the ***n*th-order exponential integral** which is readily available. Employing the definition of gas emissivity, the **mean beam length** between the plates L_M is then defined by the expression

$$\varepsilon_g = [1 - 2E_3(KL)] \equiv 1 - e^{-KL_M} \qquad (5\text{-}139b)$$

Solution of Eq. (5-139*b*) yields $KL_M = -\ln[2E_3(KL)]$, and it is apparent that KL_M is a function of KL. Since $E_n(0) = 1/(n-1)$ for $n > 1$, the mean beam length approximation also correctly predicts the gas emissivity as zero when $K = 0$ and $K \to \infty$.

In the limit $K \to 0$, power series expansion of both sides of the Eq. (5-139*b*) leads to $KL_M \to 2KL \equiv KL_{M0}$, where $L_M \equiv L_{M0} = 2L$. Here L_{M0} is defined as the **optically thin mean beam length** for radiant transfer from the entire *infinite* planar gas layer to a differential element of surface area on one of the plates. The optically thin mean beam length for two infinite parallel plates is thus simply *twice* the plate spacing L. In a similar manner it may be shown that for a sphere of diameter D, $L_{M0} = \frac{2}{3} D$, and for an infinitely long cylinder $L_{M0} = D$. A useful default formula for an arbitrary enclosure of volume V and area A is given by $L_{M0} = 4V/A$. This expression predicts $L_{M0} = \frac{8}{9} R$ for the standard hemisphere of radius R because the optically thin mean beam length is averaged over the *entire* hemispherical enclosure.

Use of the optically thin value of the mean beam length yields values of gas emissivities or exchange areas that are too high. It is thus necessary to introduce a dimensionless constant $\beta \le 1$ and define some new **average mean beam length** such that $KL_M \equiv \beta KL_{M0}$. For the case of parallel plates, we now require that the mean beam length exactly predict the gas emissivity for a *third* value of KL. In this example we find $\beta = -\ln[2E_3(KL)]/2KL$ and for $KL = 0.193095$ there results $\beta = 0.880$. The value $\beta = 0.880$ is not wholly arbitrary. It also happens to minimize the error defined by the so-called shape correction factor $\phi = [\partial(\overline{s_1 g})/\partial A_1]/(1 - e^{-KL_M})$ for all $KL > 0$. The required *average* mean beam length for all $KL > 0$ is then taken simply as $L_M = 0.88 L_{M0} = 1.76L$. The error in this approximation is less than 5 percent.

For an arbitrary geometry, the average mean beam length is defined as the radius of a hemisphere of gas which predicts values of the direct exchange area $\overline{s_1 g}/A_1 = [1 - \exp(-KL_M)]$, subject to the optimization condition indicated above. It is has been found that the error introduced by using average mean beam lengths to approximate direct exchange areas is sufficiently small to be appropriate for many engineering calculations. When $\beta = L_M/L_{M0}$ is evaluated for a large number of geometries, it is found that $0.8 < \beta < 0.95$. It is recommended here that $\beta = 0.88$ be employed in lieu of any further geometric information. For a single-gas zone, all the requisite direct exchange areas can be approximated for engineering purposes in terms of a *single* appropriately defined average mean beam length.

Emissivities of Combustion Products Absorption or emission of radiation by the constituents of gaseous combustion products is determined primarily by vibrational and rotational transitions between the energy levels of the gaseous molecules. Changes in both vibrational and rotational energy states gives rise to *discrete* spectral lines. Rotational lines accompanying vibrational transitions usually overlap, forming a so-called vibration-rotation band. These bands are thus associated with the major vibrational frequencies of the molecules.

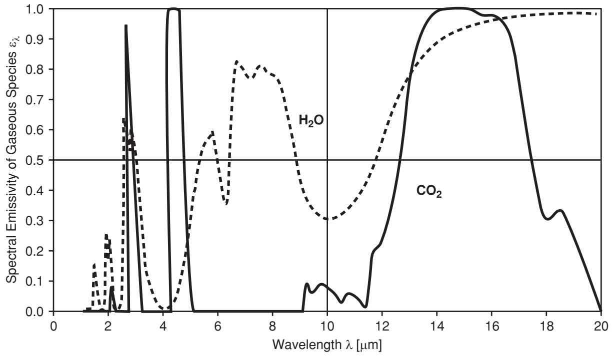

FIG. 5-21 Spectral emittances for carbon dioxide and water vapor after RADCAL. $p_cL = p_wL = 0.36$ atm·m, $T_g = 1500$ K.

Each spectral line is characterized by an absorption coefficient $k_{p,\lambda}$ which exhibits a maximum at some central characteristic wavelength or wave number $\eta_0 = 1/\lambda_0$ and is described by a Lorentz* probability distribution. Since the widths of spectral lines are dependent on collisions with other molecules, the absorption coefficient will also depend upon the composition of the combustion gases and the total system pressure. This brief discussion of gas spectroscopy is intended as an introduction to the factors controlling absorption coefficients and thus the factors which govern the empirical correlations to be presented for gas emissivities and absorptivities.

Figure 5-21 shows computed values of the spectral emissivity $\varepsilon_{g,\lambda} \equiv \varepsilon_{g,\lambda}(T,pL,\lambda)$ as a function of wavelength for an equimolar mixture of carbon dioxide and water vapor for a gas temperature of 1500 K, partial pressure of 0.18 atm, and a path length $L = 2$ m. Three principal absorption-emission bands for CO_2 are seen to be centered on 2.7, 4.3, and 15 μm. Two weaker bands at 2 and 9.7 μm are also evident. Three principal absorption-emission bands for water vapor are also identified near 2.7, 6.6, and 20 μm with lesser bands at 1.17, 1.36, and 1.87 μm. The *total* emissivity ε_g and absorptivity $\alpha_{g,1}$ are calculated by integration with respect to wavelength of the spectral emissivities, using Eqs. (5-138) in a manner similar to the development of total surface properties.

Spectral Emissivities Highly resolved spectral emissivities can be generated at ambient temperatures from the HITRAN database (*hi*gh-resolution *tran*smission molecular absorption) that has been developed for atmospheric models [Rothman, L. S., Chance, K., and Goldman, A., eds., *J. Quant. Spectroscopy & Radiative Trans.*, **82** (1–4), 2003]. This database includes the chemical species: H_2O, CO_2, O_3, N_2O, CO, CH_4, O_2, NO, SO_2, NO_2, NH_3, HNO_3, OH, HF, HCl, HBr, ClO, OCS, H_2CO, HOCl, N_2, HCN, CH_3C, HCl, H_2O_2, C_2H_2, C_2H_6, PH_3, COF_2, SF_6, H_2S, and HCO_2H. These data have been extended to high temperature for CO_2 and H_2O, allowing for the changes in the population of different energy levels and in the line half width [Denison, M. K., and Webb, B. W., *Heat Transfer*, **2**, 19–24 (1994)]. The resolution in the single-line models of emissivities is far greater than that needed in engineering calculations. A number of models are available that average the emissivities over narrow-wavelength regimes or over the entire band. An extensive set of measurements of narrowband parameters performed at NASA (Ludwig, C., et al., *Handbook of Infrared Radiation from Combustion Gases*, NASA SP-3080, 1973) has been used to develop the RADCAL computer code to obtain spectral emissivities for CO_2, H_2O, CH_4, CO, and soot (Grosshandler, W. L., "RADCAL," NIST Technical Note 1402, 1993). The exponential wideband model is available for emissions averaged over a band for H_2O, CO_2, CO, CH_4, NO, SO_2, N_2O, NH_3, and C_2H_2 [Edwards, D. K., and Menard, W. A., *Appl. Optics*, **3,** 621–625 (1964)]. The line and band models have the advantages of being able to account for complexities in determining emissivities of line broadening due to changes in composition and pressure, exchange with spectrally selective walls, and greater accuracy in formulating fluxes in gases with temperature gradients. These models can be used to generate the total emissivities and absorptivies that will be used in this chapter. RADCAL is a command-line FORTRAN code which is available in the public domain on the Internet.

*Spectral lines are conventionally described in terms of wave number $\eta = 1/\lambda$, with each line having a peak absorption at wave number η_0. The Lorentz distribution is defined as $k_\eta/S = \dfrac{b_c}{\pi[b_c^2 + (\eta - \eta_o)^2]}$ where S is the integral of k_η over all wave numbers. The parameter S is known as the integrated line intensity, and b_c is defined as the collision line half-width, i.e., the half-width of the line is one-half of its peak centerline value. The units of k_η are m^{-1} atm^{-1}.

Total Emissivities and Absorptivities Total emissivities and absorptivities for water vapor and carbon dioxide at present are still based on data embodied in the classical **Hottel emissivity charts.** These data have been adjusted with the more recent measurements in RADCAL and used to develop the correlations of emissivities given in Table 5-5. Two empirical correlations which permit hand calculation of emissivities for water vapor, carbon dioxide, and *four* mixtures of the two gases are presented in Table 5-5. The first section of Table 5-5 provides data for the two constants b and n in the empirical relation

$$\overline{\varepsilon_g T_g} = b[pL - 0.015]^n \qquad (5\text{-}140a)$$

while the second section of Table 5-5 utilizes the *four* constants in the empirical correlation

$$\log(\overline{\varepsilon_g T_g}) = a_0 + a_1 \log(pL) + a_2 \log^2(pL) + a_3 \log^3(pL) \qquad (5\text{-}140b)$$

In both cases the empirical constants are given for the three temperatures of 1000, 1500, and 2000 K. Table 5-5 also includes some six values for the partial pressure ratios p_W/p_C of water vapor to carbon dioxide, namely, 0, 0.5, 1.0, 2.0, 3.0, and ∞. These ratios correspond to composition values of $p_C/(p_C + p_W) = 1/(1 + p_W/p_C)$ of 0, 1/3, 1/2, 2/3, 3/4, and unity. For emissivity calculations at other temperatures and mixture compositions, linear interpolation of the constants is recommended.

The absorptivity can be obtained from the emissivity with aid of Table 5-5 by using the following functional equivalence.

$$\overline{\alpha_{g,1} T_1} = [\overline{\varepsilon_g T_1}(pL \cdot T_1/T_g)]\left(\frac{T_g}{T_1}\right)^{0.5} \qquad (5\text{-}141)$$

Verbally, the absorptivity computed from Eq. (5-141) by using the correlations in Table 5-5 is based on a value for gas emissivity ε_g calculated at a temperature T_1 and at a partial-pressure path-length product of $(p_C + p_W)LT_1/T_g$. The absorptivity is then equal to this value of gas emissivity multiplied by $(T_g/T_1)^{0.5}$. It is recommended that spectrally based models such as RADCAL (loc. cit.) be used particularly when extrapolating beyond the temperature, pressure, or partial-pressure-length product ranges presented in Table 5-5.

A comparison of the results of the predictions of Table 5-5 with values obtained via the integration of the spectral results calculated from the narrowband model in RADCAL is provided in Fig. 5-22. Here calculations are shown for $p_CL = p_WL = 0.12$ atm·m and a gas temperature of 1500 K. The RADCAL predictions are 20 percent higher than the measurements at low values of pL and are 5 percent higher at the large values of pL. An extensive comparison of different sources of emissivity data shows that disparities up to 20 percent are to be expected at the current time [Lallemant, N., Sayre, A., and Weber, R., *Prog. Energy Combust. Sci.*, **22,** 543–574, (1996)]. However, smaller errors result for the range of the total emissivity measurements presented in the Hottel emissivity tables. This is demonstrated in Example 11.

Example 11: Calculations of Gas Emissivity and Absorptivity Consider a slab of gas confined between two infinite parallel plates with a distance of separation of $L = 1$ m. The gas pressure is 101.325 kPa (1 atm), and the gas temperature is 1500 K (2240°F). The gas is an equimolar mixture of CO_2 and H_2O, each with a partial pressure of 12 kPa ($p_C = p_W = 0.12$ atm). The radiative flux to one of its bounding surfaces has been calculated by using RADCAL for two cases. For case (*a*) the flux to the bounding surface is 68.3 kW/m² when the emitting gas is backed by a black surface at an ambient temperature of 300 K (80°F). This (cold) back surface contributes less than 1 percent to the flux. In case (*b*), the flux is calculated as 106.2 kW/m² when the gas is backed by a black surface at a temperature of 1000 K (1340°F). In this example, gas emissivity and

NOTE: $p_w/(p_w + p_c)$ of ⅓, ½, ⅔, and ¾ may be used to cover the ranges 0.2–0.4, 0.4–0.6, 0.6–0.7, and 0.7–0.8, respectively, with a maximum error in ε_g of 5 percent at pL = 6.5 m·atm, less at lower pL's. Linear interpolation reduces the error generally to less than 1 percent. Linear interpolation or extrapolation on T introduces an error generally below 2 percent, less than the accuracy of the original data.

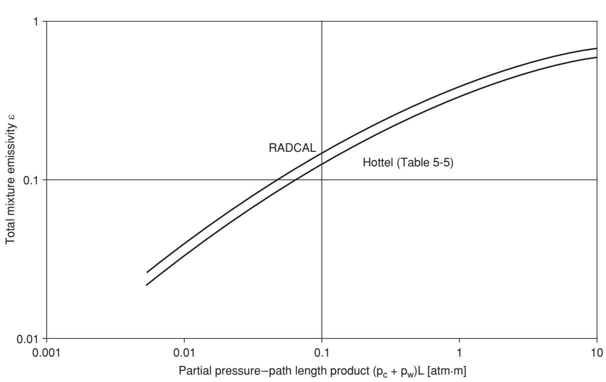

FIG. 5-22 Comparison of Hottel and RADCAL total gas emissivities. Equimolal gas mixture of CO_2 and H_2O with $p_c = p_w = 0.12$ atm and T_g = 1500 K.

absorptivity are to be computed from these flux values and compared with values obtained by using Table 5-5.

Case (a): The flux incident on the surface is equal to $\varepsilon_g \cdot \sigma \cdot T_g^4 = 68.3$ kW/m²; therefore, $\varepsilon_g = 68{,}300/(5.6704 \times 10^{-8} \cdot 1500^4) = 0.238$. To utilize Table 5-5, the mean beam length for the gas is calculated from the relation $L_M = 0.88 L_{M0} = 0.88 \cdot 2L = 1.76$ m. For T_g = 1500 K and $(p_C + p_W)L_M = 0.24(1.76) = 0.422$ atm·m, the two-constant correlation in Table 5-5 yields $\varepsilon_g = 0.230$ and the four-constant correlation yields $\varepsilon_g = 0.234$. These results are clearly in excellent agreement with the predicted value of $\varepsilon_g = 0.238$ obtained from RADCAL.

Case (b): The flux incident on the surface (106.2 kW/m²) is the sum of that contributed by (1) gas emission $\varepsilon_g \cdot \sigma \cdot T_g^4 = 68.3$ kW/m² and (2) emission from the opposing surface corrected for absorption by the intervening gas using the gas transmissivity, that is, $\tau_{g,1} \sigma \cdot T_1^4$ where $\tau_{g,1} = 1 - \alpha_{g,1}$. Therefore $\alpha_{g,1} = [1 - (106{,}200 - 68{,}300)/(5.6704 \times 10^{-8} \cdot 1000^4)] = 0.332$. Using Table 5-5, the two-constant and four-constant gas emissivities evaluated at T_1 = 1000 K and $pL = 0.4224 \cdot (1000/1500) = 0.282$ atm·m are $\varepsilon_g = 0.2654$ and $\varepsilon_g = 0.2707$, respectively. Multiplication by the factor $(T_g / T_1)^{0.5} = (1500 / 1000)^{0.5} = 1.225$ produces the final values of the two corresponding gas absorptivities $\alpha_{g,1} = 0.325$ and $\alpha_{g,1} = 0.332$, respectively. Again the agreement with RADCAL is excellent.

Other Gases The most extensive available data for gas emissivity are those for carbon dioxide and water vapor because of their importance in the radiation from the products of fossil fuel combustion. Selected data for other species present in combustion gases are provided in Table 5-6.

Flames and Particle Clouds

Luminous Flames Luminosity conventionally refers to soot radiation. At atmospheric pressure, soot is formed in locally fuel-rich portions of flames in amounts that usually correspond to less than 1 percent of the carbon in the fuel. Because soot particles are small relative to the wavelength of the radiation of interest in flames (primary particle diameters of soot are of the order of 20 nm compared to wavelengths of interest of 500 to 8000 nm), the incident radiation permeates the particles, and the absorption is proportional to the volume of the particles. In the limit of $r_p/\lambda << 1$, the Rayleigh limit, the monochromatic emissivity ε_λ is given by

$$\varepsilon_\lambda = 1 - \exp(-K\cdot f_v\cdot L/\lambda) \tag{5-142}$$

where f_v is the volumetric soot concentration, L is the path length in the same units as the wavelength λ, and K is dimensionless. The value K will vary with fuel type, experimental conditions, and the temperature history of the soot. The values of K for a wide range of systems are within a factor of about 2 of one another. The single most important variable governing the value of K is the hydrogen/carbon ratio of the soot, and the value of K increases as the H/C ratio decreases. A value of $K = 9.9$ is recommended on the basis of seven studies involving 29 fuels [Mulholland, G. W., and Croarkin, C., *Fire and Materials*, **24,** 227–230 (2000)].

The total emissivity of soot ε_S can be obtained by substituting ε_λ from Eq. (5-142) for ε_λ in Eq. (5-138*a*) to yield

$$\varepsilon_S = \int_{\lambda=0}^{\infty} \varepsilon_\lambda \frac{E_{b,\lambda}(T_g,\lambda)}{E_b(T_g)}\, d\lambda = 1 - \frac{15}{4}\left[\Psi^{(3)}(1 + K\cdot f_v\cdot L\cdot T/c_2)\right]$$

$$\cong (1 + K\cdot f_v\cdot L\cdot T/c_2)^{-4} \tag{5-143}$$

Here $\Psi^{(3)}(x)$ is defined as the pentagamma function of x and c_2 (m·K) is again Planck's second constant. The approximate relation in Eq. (5-143) is accurate to better than 1 percent for arguments yielding values of $\varepsilon_S < 0.7$. At present, the largest uncertainty in estimating total soot emissivities is in the estimation of the soot volume fraction f_v. Soot forms in the fuel-rich zones of flames. Soot formation rates are a function of fuel type, mixing rate, local equivalence ratio Φ, temperature, and pressure. The equivalence ratio is defined as the quotient of the actual to stoichiometric fuel-to-oxidant ratio $\Phi = [F/O]_{Act}/[F/O]_{Stoich}$. Soot formation increases with the aromaticity or C/H ratio of fuels with benzene, α-methyl naphthalene, and acetylene having a high propensity to form soot and methane having a low soot formation propensity. Oxygenated fuels, such as alcohols, emit little soot. In practical turbulent diffusion flames, soot forms on the fuel side of the flame front. In premixed flames, at a given temperature, the rate of soot formation increases rapidly for $\Phi > 2$. For temperatures above 1500 K, soot burns out rapidly (in less than 0.1s) under fuel-lean conditions, $\Phi < 1$. Because of this rapid soot burnout, soot is usually localized in a relatively small fraction of a furnace or combustor volume. Long, poorly mixed diffusion flames promote soot formation while highly backmixed combustors can burn soot-free. In a typical flame at atmospheric pressure, maximum volumetric soot concentrations are found to be in the range $10^{-7} < f_v < 10^{-6}$. This corresponds to a soot formation of about 1.5 to 15 percent of the carbon in the fuel. When f_v is to be calculated at high pressures, allowance must be made for the significant increase in soot formation with pressure and for the inverse proportionality of f_v with respect to pressure. Great progress is being made in the ability to calculate soot in premixed flames. For example, predicted and measured soot concentration have been compared in a well-stirred reactor operated over a wide range of temperatures and equivalence ratios [Brown, N.J. Revzan, K. L., Frenklach, M., *Twenty-seventh Symposium (International) on Combustion*, pp. 1573–1580, 1998]. Moreover, CFD (computational fluid dynamics) and population dynamics modeling have been used to simulate soot formation in a turbulent non-premixed ethylene-air flame [Zucca, A., Marchisio, D. L., Barresi, A. A., Fox, R. O., *Chem. Eng. Sci.,* 2005]. The importance of soot radiation varies widely between combustors. In large boilers the soot is confined to small volumes and is of only local importance. In gas turbines, cooling the combustor liner is of primary importance so that only small incremental soot radiation is of concern. In high-temperature glass tanks, the presence of soot adds 0.1 to 0.2 to emissivities of oil-fired flames. In natural gas-fired flames, efforts to augment flame emissivities with soot generation have generally been unsuccessful. The contributions of soot to the radiation from pool fires often dominates, and thus the presence of soot in such flames directly impacts the safe separation distances from dikes around oil tanks and the location of flares with respect to oil rigs.

Clouds of Large Black Particles The emissivity ε_M of a cloud of black particles with a large perimeter-to-wavelength ratio is

$$\varepsilon_M = 1 - \exp[-(a/v)L] \tag{5-144}$$

where a/v is the projected area of the particles per unit volume of space. If the particles have no negative curvature (the particle does not "see" any of itself) and are randomly oriented, $a = a'/4$, where a' is the actual surface area. If the particles are uniform, $a/v = cA = cA'/4$, where A and A' are the projected and total areas of each particle and c is the number concentration of particles. For spherical particles this leads to

$$\varepsilon_M = 1 - \exp[-(\pi/4)cd_p^2L] = 1 - \exp(-1.5f_vL/d_p) \tag{5-145}$$

As an example, consider a heavy fuel oil ($CH_{1.5}$, specific gravity, 0.95) atomized to a mean surface particle diameter of d_p burned with

20 percent excess air to produce coke-residue particles having the original drop diameter and suspended in combustion products at 1204°C (2200°F). The flame emissivity due to the particles along a path of L m, with d_p measured in micrometers, is

$$\varepsilon_M = 1 - \exp(-24.3L/d_p) \tag{5-146}$$

For 200-μm particles and L = 3.05 m, the particle contribution to emissivity is calculated as 0.31.

Clouds of Nonblack Particles For nonblack particles, emissivity calculations are complicated by multiple scatter of the radiation reflected by each particle. The emissivity ε_M of a cloud of gray particles of individual emissivity ε_1 can be estimated by the use of a simple modification Eq. (5-144), i.e.,

$$\varepsilon_M = 1 - \exp[-\varepsilon_1(a/v)L] \tag{5-147}$$

Equation (5-147) predicts that $\varepsilon_M \rightarrow 1$ as $L \rightarrow \infty$. This is *impossible* in a scattering system, and use of Eq. (5-147) is restricted to values of the optical thickness $(a/v)\ L < 2$. Instead, the asymptotic value of ε_M is obtained from Fig. 5-12 as $\varepsilon_M = \varepsilon_h$ (lim $L \rightarrow \infty$), where the albedo ω is replaced by the particle-surface reflectance $\omega = 1 - \varepsilon_1$. Particles with perimeter-to-wavelength ratios of 0.5 to 5.0 can be analyzed, with significant mathematical complexity, by use of the the *Mie equations* (Bohren, C. F., and Huffman, D. R., *Absorption and Scattering of Light by Small Particles*, Wiley, 1998).

Combined Gas, Soot, and Particulate Emission In a mixture of emitting species, the emission of each constituent is attenuated on its way to the system boundary by absorption by all other constituents. The transmissivity of a mixture is the product of the transmissivities of its component parts. This statement is a corollary of Beer's law. For present purposes, the transmissivity of "species k" is defined as $\tau_k = 1 - \varepsilon_k$. For a mixture of combustion products consisting of carbon dioxide, water vapor, soot, and oil coke or char particles, the total emissivity ε_T at any wavelength can therefore be obtained from

$$(1 - \varepsilon_T)_\lambda = (1 - \varepsilon_C)_\lambda(1 - \varepsilon_W)_\lambda(1 - \varepsilon_S)_\lambda(1 - \varepsilon_M)_\lambda \tag{5-148}$$

where the subscripts denote the four flame species. The total emissivity is then obtained by integrating Eq. (5-148) over the entire EM energy spectrum, taking into account the variability of ε_C, ε_W, and ε_S with respect to wavelength. In Eq. (5-148), ε_M is independent of wavelength because absorbing char or coke particles are effectively blackbody absorbers. Computer programs for spectral emissivity, such as RADCAL (loc. cit.), perform the integration with respect to wavelength for obtaining total emissivity. Corrections for the overlap of vibration-rotation bands of CO_2 and H_2O are automatically included in the correlations for ε_g for mixtures of these gases. The monochromatic soot emissivity is higher at shorter wavelengths, resulting in higher attenuations of the bands at 2.7 μm for CO_2 and H_2O than at longer wavelengths. The following equation is recommended for calculating the emissivity ε_{g+S} of a mixture of CO_2, H_2O, and soot

$$\varepsilon_{g+S} = \varepsilon_g + \varepsilon_S - M\cdot\varepsilon_g\varepsilon_S \tag{5-149}$$

where M can be represented with acceptable error by the dimensionless function

$$M = 1.12 - 0.27\cdot(T/1000) + 2.7 \times 10^5 f_v\cdot L \tag{5-150}$$

In Eq. (5-150), T has units of kelvins and L is measured in meters. Since coke or char emissivities are gray, their addition to those of the CO_2, H_2O, and soot follows simply from Eq. (5-148) as

$$\varepsilon_T = \varepsilon_{g+S} + \varepsilon_M - \varepsilon_{g+S}\varepsilon_M \tag{5-151}$$

with the definition $1 - \varepsilon_{g+S} \equiv (1 - \varepsilon_C)(1 - \varepsilon_W)(1 - \varepsilon_S)$.

RADIATIVE EXCHANGE WITH PARTICIPATING MEDIA

Energy Balances for Volume Zones—The Radiation Source Term Reconsider a generalized enclosure with N volume zones confining a *gray* gas. When the N gas temperatures are *unknown*, an *additional* set of N equations is required in the form of radiant energy balances for each volume zone. These N equations are given by the *definition* of the N-vector for the **net radiant volume absorption** $\mathbf{S'} = [S'_j]$ for each volume zone

$$\mathbf{S'} = \overline{\mathbf{GS}}\cdot\mathbf{E} + \overline{\mathbf{GG}}\cdot\mathbf{E_g} - 4K\mathbf{VI}\cdot\mathbf{E_g} \qquad [N \times 1] \tag{5-152}$$

The radiative source term is a discretized formulation of the *net radiant absorption* for each volume zone which may be incorporated as a *source term* into numerical approximations for the generalized *energy equation.* As such, it permits formulation of energy balances on each zone that may include conductive and convective heat transfer. For $K \rightarrow 0$, $\overline{\mathbf{GS}} \rightarrow 0$, and $\overline{\mathbf{GG}} \rightarrow 0$ leading to $\mathbf{S'} \rightarrow \mathbf{0_N}$. When $K \neq 0$ and $\mathbf{S'} = \mathbf{0_N}$, the gas is said to be in a state of *radiative equilibrium.* In the notation usually associated with the discrete ordinate (DO) and finite volume (FV) methods, see Modest (op. cit., Chap. 16), one would write $S'_i/V_i = K[G - 4\cdot E_g] = -\nabla\cdot\vec{q}_r$. Here $H_g = G/4$ is the average flux density incident on a given volume zone from all other surface and volume zones. The DO and FV methods are currently available options as "RTE-solvers" in complex simulations of combustion systems using *computational fluid dynamics* (CFD).*

Implementation of Eq. (5-152) necessitates the definition of two additional *symmetric* $N \times N$ arrays of exchange areas, namely, $\overline{\mathbf{gg}} = [\overline{g_ig_j}]$ and $\overline{\mathbf{GG}} = [\overline{G_iG_j}]$. In Eq. (5-152) $\mathbf{VI} = [Vj\cdot\delta_{ij}]$ is an $N \times N$ diagonal matrix of zone volumes. The total exchange areas in Eq. (5-151) are *explicit* functions of the direct exchange areas as follows:

Surface-to-gas exchange

$$\overline{\mathbf{GS}} = \overline{\mathbf{SG}}^T \qquad [N \times M] \tag{5-153a}$$

Gas-to-gas exchange

$$\overline{\mathbf{GG}} = \overline{\mathbf{gg}} + \overline{\mathbf{sg}}^T\cdot\rho\mathbf{I}\cdot\mathbf{R}\cdot\overline{\mathbf{sg}} \qquad [N \times M] \tag{5-153b}$$

The matrices $\overline{\mathbf{gg}} = [\overline{g_ig_j}]$ and $\overline{\mathbf{GG}} = [\overline{G_iG_j}]$ must also satisfy the following **matrix conservation relations:**

Direct exchange areas: $4K\mathbf{VI}\cdot\mathbf{1}_N = \overline{\mathbf{gs}}\cdot\mathbf{1}_M + \overline{\mathbf{gg}}\cdot\mathbf{1}_N$ (5-154*a*)

Total exchange areas: $4K\mathbf{VI}\cdot\mathbf{1}_N = \overline{\mathbf{GS}}\cdot\mathbf{1}_M + \overline{\mathbf{GG}}\cdot\mathbf{1}_N$ (5-154*b*)

The formal integral definition of the direct gas-gas exchange area is

$$\overline{g_ig_j} = \iiint_{V_i}\iiint_{V_j} K^2 \frac{e^{-Kr}}{\pi r^2}\, dV_j\, dV_i \tag{5-155}$$

Clearly, when $K = 0$, the two direct exchange areas involving a gas zone $\overline{\mathbf{g_is_j}}$ and $\overline{\mathbf{g_ig_j}}$ vanish. Computationally it is *never* necessary to make resort to Eq. (5-155) for calculation of $\overline{g_ig_j}$. This is so because $\overline{s_ig_j}$, $\overline{g_is_j}$, and $\overline{g_ig_j}$ may *all* be calculated *arithmetically* from appropriate values of $\overline{s_is_j}$ by using associated conservation relations and view factor algebra.

Weighted Sum of Gray Gas (WSGG) Spectral Model Even in simple engineering calculations, the assumption of a gray gas is almost never a good one. The zone method is now further generalized to make allowance for nongray radiative transfer via incorporation of the **weighted sum of gray gas** (WSGG) spectral model. Hottel has shown that the emissivity $\varepsilon_g(T,L)$ of an absorbing-emitting gas mixture containing CO_2 and H_2O of known composition can be approximated by a *weighted sum of P gray gases*

$$\varepsilon_g(T,L) \approx \sum_{p=1}^{P} a_p(T)(1 - e^{-K_pL}) \tag{5-156a}$$

where

$$\sum_{p=1}^{P} a_p(T) = 1.0 \tag{5-156b}$$

In Eqs. (5-156), K_p is some gray gas absorption coefficient and L is some appropriate path length. In practice, Eqs. (5-156) usually yield acceptable accuracy for $P \leq 3$. For $P = 1$, Eqs. (5-156) degenerate to the case of a single gray gas.

*To further clarify the mathematical differences between zoning and the DO and FV methods recognize that (neglecting scatter) the matrix expressions $\mathbf{H} = \mathbf{AI}^{-1}\cdot\overline{\mathbf{ss}}\cdot\mathbf{W} + \mathbf{AI}^{-1}\cdot\overline{\mathbf{sg}}\cdot\mathbf{E_g}$ and $4K\cdot\mathbf{H_g} = \mathbf{VI}^{-1}\cdot\overline{\mathbf{gs}}\cdot\mathbf{W} + \mathbf{VI}^{-1}\cdot\overline{\mathbf{gg}}\cdot\mathbf{E_g}$ represent spatial discretizations of the integral form(s) of the RTE applied at any point (zone) on the boundary or interior of an enclosure, respectively, for a gray gas.

The Clear plus Gray Gas WSGG Spectral Model In principle, the emissivity of all gases approaches unity for infinite path length L. In practice, however, the gas emissivity may fall considerably short of unity for representative values of pL. This behavior results because of the *band* nature of real gas spectral absorption and emission whereby there is usually no significant overlap between dominant absorption bands. Mathematically, this physical phenomenon is modeled by defining one of the gray gas components in the WSGG spectral model to be *transparent*.

For $P = 2$ and path length L_M, Eqs. (5-156) yield the following expression for the gas emissivity

$$\varepsilon_g = a_1(1 - e^{-K_1L_M}) + a_2(1 - e^{-K_2L_M}) \tag{5-157}$$

In Eq. (5-157) if $K_1 = 0$ and $a_2 \neq 0$, the limiting value of gas emissivity is $\varepsilon_g(T,\infty) \to a_2$. Put $K_1 = 0$ in Eq. (5-157), $a_g = a_2$, and define $\tau_g = e^{-K_2L_M}$ as the gray gas transmissivity. Equation (5-157) then simplifies to

$$\varepsilon_g = a_g(1 - \tau_g) \tag{5-158}$$

It is important to note in Eq. (5-158) that $0 \leq a_g,\ \tau_g \leq 1.0$ while $0 \leq \varepsilon_g \leq a_g$.

Equation (5-158) constitutes a two-parameter model which may be fitted with only *two* empirical emissivity data points. To obtain the constants a_g and τ_g in Eq. (5-158) at fixed composition and temperature, denote the two emissivity data points as $\varepsilon_{g,2} = \varepsilon_g(2pL) > \varepsilon_{g,1} = \varepsilon_g(pL)$ and recognize that $\varepsilon_{g,1} = a_g(1 - \tau_g)$ and $\varepsilon_{g,2} = a_g(1 - \tau_g^2) = a_g(1 - \tau_g)(1 + \tau_g) = \varepsilon_{g,1}(1 + \tau_g)$. These relations lead directly to the final emissivity fitting equations

$$\tau_g = \frac{\varepsilon_{g,2}}{\varepsilon_{g,1}} - 1 \tag{5-159a}$$

and

$$a_g = \frac{\varepsilon_{g,1}}{2 - \varepsilon_{g,2}/\varepsilon_{g,1}} \tag{5-159b}$$

The clear plus gray WSGG spectral model also readily leads to values for gas *absorptivity* and *transmissivity*, with respect to some appropriate surface radiation source at temperature T_1, for example,

$$\alpha_{g,1} = a_{g,1}(1 - \tau_g) \tag{5-160a}$$

and

$$\tau_{g,1} = a_{g,1} \cdot \tau_g \tag{5-160b}$$

In Eqs. (5-160) the *gray* gas transmissivity τ_g is taken to be identical to that obtained for the gas emissivity ε_g. The constant $a_{g,1}$ in Eq. (5-160*a*) is then obtained with knowledge of *one additional empirical value* for $\alpha_{g,1}$ which may also be obtained from the correlations in Table 5-5. Notice further in the definitions of the three parameters ε_g, $\alpha_{g,1}$, and $\tau_{g,1}$ that *all* the temperature dependence is forced into the *two* WSGG constants a_g and $a_{g,1}$.

The *three* clear plus gray WSGG constants a_g, $a_{g,1}$, and τ_g are functions of total pressure, temperature, and mixture composition. It is not necessary to ascribe any particular physical significance to them. Rather, they may simply be visualized as three constants that happen to fit the gas emissivity data. It is noteworthy that *three* constants are far fewer than the number required to calculate gas emissivity data from fundamental spectroscopic data. The two constants a_g and $a_{g,1}$ defined in Eqs. (5-158) and (5-160) can, however, be interpreted *physically* in a particularly simple manner. Suppose the gas absorption spectrum is idealized by *many* absorption bands (boxes), *all* of which are characterized by the *identical* absorption coefficient K. The a's might then be calculated from the total blackbody energy fraction F_b (λT) defined in Eqs. (5-105) and (5-106). That is, a_g simply represents the total *energy fraction* of the blackbody energy distribution in which the gas *absorbs*. This concept may be further generalized to real gas absorption spectra via the *wideband stepwise gray spectral box model* (Modest, op. cit., Chap. 14).

When $P \geq 3$, exponential curve-fitting procedures for the WSGG spectral model become significantly more difficult for hand computation but are quite routine with the aid of a variety of readily available mathematical software utilities. The clear plus gray WSGG fitting procedure is demonstrated in Example 8.

The Zone Method and Directed Exchange Areas Spectral dependence of real gas spectral properties is now introduced into the zone method via the WSGG spectral model. It is still assumed, however, that all surface zones are gray isotropic emitters and absorbers.

General Matrix Representation We first define a new set of four **directed exchange areas** $\overleftarrow{\mathbf{SS}}$, $\overleftarrow{\mathbf{SG}}$, $\overleftarrow{\mathbf{GS}}$, and $\overleftarrow{\mathbf{GG}}$ which are denoted by an overarrow. The directed exchange areas are obtained from the total exchange areas for gray gases by simple matrix multiplication using weighting factors derived from the WSGG spectral model. The directed exchange areas are denoted by an overarrow to indicate the "sending" and "receiving" zone. The a-weighting factors for transfer originating at a gas zone $a_{g,i}$ are derived from WSGG gas *emissivity* calculations, while those for transfers originating at a surface zone, a_i are derived from appropriate WSGG gas *absorptivity* calculations. Let $\mathbf{agI}_p = [a_{p,g,i}\delta_{i,j}]$ and $\mathbf{aI}_p = [a_{p,i}\delta_{i,j}]$ represent the P $[M \times M]$ and $[N \times N]$ *diagonal* matrices comprised of the appropriate WSGG *a* constants. The *directed* exchange areas are then computed from the associated *total* gray gas exchange areas via simple *diagonal* matrix multiplication.

$$\overleftarrow{\mathbf{SS}} = \sum_{p=1}^{P} \overline{\mathbf{SS}}_p \cdot \mathbf{aI}_p \qquad [M \times M] \tag{5-161a}$$

$$\overleftarrow{\mathbf{SG}} = \sum_{p=1}^{P} \overline{\mathbf{SG}}_p \cdot \mathbf{agI}_p \qquad [M \times N] \tag{5-161b}$$

$$\overleftarrow{\mathbf{GS}} = \sum_{p=1}^{P} \overline{\mathbf{GS}}_p \cdot \mathbf{aI}_p \qquad [M \times N] \tag{5-161c}$$

$$\overleftarrow{\mathbf{GG}} = \sum_{p=1}^{P} \overline{\mathbf{GG}}_p \cdot \mathbf{agI}_p \qquad [N \times N] \tag{5-161d}$$

with

$$\overleftarrow{\mathbf{KI}} = \sum_{p=1}^{P} \mathbf{KI}_p \cdot \mathbf{agI}_p \qquad [N \times N] \tag{5-161e}$$

In contrast to the *total* exchange areas which are always independent of temperature, the four *directed* arrays $\overleftarrow{\mathbf{SS}}$, $\overleftarrow{\mathbf{SG}}$, $\overleftarrow{\mathbf{GS}}$, and $\overleftarrow{\mathbf{GG}}$ are dependent on the temperatures of each and every zone, i.e., as in $a_{p,i} = a_p(T_i)$. Moreover, in contrast to *total* exchange areas, the *directed* arrays $\overleftarrow{\mathbf{SS}}$ and $\overleftarrow{\mathbf{GG}}$ are generally not symmetric and $\overleftarrow{\mathbf{GS}} \neq \overleftarrow{\mathbf{SG}}^T$. Finally, since the directed exchange areas are temperature-*dependent*, iteration may be required to update the $\mathbf{aI}_p$ and $\mathbf{a}_g\mathbf{I}_p$ arrays during the course of a calculation. There is a great deal of latitude with regard to fitting the WSGG *a* constants in these matrix equations, especially if $N > 1$ and composition variations are to be allowed for in the gas. An extensive discussion of *a* fitting for $N > 1$ is beyond the scope of this presentation. Details of the fitting procedure, however, are presented in Example 12 in the context of a single-gas zone.

Having formulated the directed exchange areas, the governing matrix equations for the radiative flux equations at each surface zone and the radiant source term are then given as follows:

$$\mathbf{Q} = \varepsilon\mathbf{AI} \cdot \mathbf{E} - \overleftarrow{\mathbf{SS}} \cdot \mathbf{E} - \overleftarrow{\mathbf{SG}} \cdot \mathbf{E}_g \tag{5-162a}$$

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g + \overleftarrow{\mathbf{GS}} \cdot \mathbf{E} - 4\overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{E}_g \tag{5-162b}$$

or the alternative forms

$$\mathbf{Q} = [\mathbf{EI} \cdot \overrightarrow{\mathbf{SS}} - \overleftarrow{\mathbf{SS}} \cdot \mathbf{EI}] \cdot \mathbf{1}_M + [\mathbf{EI} \cdot \overrightarrow{\mathbf{SG}} - \overleftarrow{\mathbf{SG}} \cdot \mathbf{E}_g\mathbf{I}] \cdot \mathbf{1}_N \tag{5-163a}$$

$$\mathbf{S}' = -[\mathbf{E}_g\mathbf{I} \cdot \overrightarrow{\mathbf{GS}} - \overleftarrow{\mathbf{GS}} \cdot \mathbf{EI}] \cdot \mathbf{1}_M - [\mathbf{E}_g\mathbf{I} \cdot \overrightarrow{\mathbf{GG}} - \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g\mathbf{I}] \cdot \mathbf{1}_N \tag{5-163b}$$

It may be *proved* that the $\mathbf{Q}$ and $\mathbf{S}'$ vectors computed from Eqs. (5-162) and (5-163) always *exactly* satisfy the overall (scalar) *radiant* energy balance $\mathbf{1}_M^T \cdot \mathbf{Q} = \mathbf{1}_N^T \cdot \mathbf{S}'$. In words, the total radiant gas emission for all gas zones in the enclosure must always exactly equal the total radiant energy received at all surface zones which comprise the enclosure. In Eqs. (5-162) and (5-163), the following definitions are employed for the *four forward-directed* exchange areas

$$\overrightarrow{\mathbf{SS}} = \overleftarrow{\mathbf{SS}}^T \qquad \overrightarrow{\mathbf{SG}} = \overleftarrow{\mathbf{GS}}^T \qquad \overrightarrow{\mathbf{GS}} = \overleftarrow{\mathbf{SG}}^T \qquad \overrightarrow{\mathbf{GG}} = \overleftarrow{\mathbf{GG}}^T \tag{5-64a,b,c,d}$$

such that formally there are some *eight* matrices of directed exchange areas. The four *backward-directed* arrays of directed exchange areas must satisfy the following conservation relations

$$\overleftarrow{\mathbf{SS}}\cdot\mathbf{1}_M + \overleftarrow{\mathbf{SG}}\cdot\mathbf{1}_N = \varepsilon\mathbf{I}\cdot\mathbf{AI}\cdot\mathbf{1}_M \tag{5-165a}$$

$$4\overleftarrow{\mathbf{KI}}\cdot\mathbf{VI}\cdot\mathbf{1}_N = \overleftarrow{\mathbf{GS}}\cdot\mathbf{1}_M + \overleftarrow{\mathbf{GG}}\cdot\mathbf{1}_N \tag{5-165b}$$

Subject to the restrictions of no scatter and diffuse surface emission and reflection, the above equations are the most general matrix statement possible for the zone method. When $P = 1$, the *directed* exchange areas all reduce to the *total* exchange areas for a single gray gas. If, in addition, $K = 0$, the much simpler case of radiative transfer in a transparent medium results. If, in addition, all surface zones are *black*, the direct, total, and directed exchange areas are all identical.

Allowance for Flux Zones As in the case of a transparent medium, we now distinguish between source and flux surface zones. Let $M = M_s + M_f$ represent the total number of surface zones where M_s is the number of source-sink zones and M_f is the number of flux zones. The flux zones are the *last to be numbered.* To accomplish this, partition the surface emissive power and flux vectors as $\mathbf{E} = \begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix}$ and $\mathbf{Q} = \begin{bmatrix}\mathbf{Q}_1\\ \mathbf{Q}_2\end{bmatrix}$, where the subscript 1 denotes surface source/sink zones whose emissive power $\mathbf{E}_1$ is specified a priori, and subscript 2 denotes surface flux zones of unknown emissive power vector $\mathbf{E}_2$ and known radiative flux vector $\mathbf{Q}_2$. Suppose the radiative source vector $\mathbf{S}'$ is *known*. Appropriate partitioning of Eqs. (5-162) then produces

$$\begin{bmatrix}\mathbf{Q}_1\\ \mathbf{Q}_2\end{bmatrix} = \begin{bmatrix}\varepsilon\mathbf{AI}_{1,1} & \mathbf{0}\\ \mathbf{0} & \varepsilon\mathbf{AI}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix}\begin{bmatrix}\overleftarrow{\mathbf{SS}}_{1,2} & \overleftarrow{\mathbf{SS}}_{1,2}\\ \overleftarrow{\mathbf{SS}}_{2,1} & \overleftarrow{\mathbf{SS}}_{2,2}\end{bmatrix}\cdot\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overleftarrow{\mathbf{SG}}_1\\ \overleftarrow{\mathbf{SG}}_1\end{bmatrix}\cdot\mathbf{E}_g \tag{5-166a}$$

and

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}}\cdot\mathbf{E}_g + \left[\overleftarrow{\mathbf{GS}}_1\ \ \overleftarrow{\mathbf{GS}}_2\right]\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - 4\overleftarrow{\mathbf{KI}}\cdot\mathbf{VI}\cdot\mathbf{E}_g \tag{5-166b}$$

where the definitions of the matrix partitions follow the conventions with respect to Eq. (5-120). Simultaneous solution of the *two* unknown vectors in Eqs. (5-166) then yields

$$\mathbf{E}_2 = \mathbf{RP}\cdot\left[\overleftarrow{\mathbf{SS}}_{2,1} + \overleftarrow{\mathbf{SG}}_2\cdot\mathbf{PP}\cdot\overleftarrow{\mathbf{GS}}_1\right]\cdot\mathbf{E}_1 + \mathbf{RP}\cdot\left[\mathbf{Q}_2 - \overleftarrow{\mathbf{SG}}_2\cdot\mathbf{PP}\cdot\mathbf{S}'\right] \tag{5-167a}$$

and

$$\mathbf{E}_g = \mathbf{PP}\cdot\left[\overleftarrow{\mathbf{GS}}_1\ \ \overleftarrow{\mathbf{GS}}_2\right]\begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \mathbf{PP}\cdot\mathbf{S}' \tag{5-167b}$$

where two auxiliary inverse matrices **RP** and **PP** are defined as

$$\mathbf{PP} = \left[4\overleftarrow{\mathbf{KI}}\cdot\mathbf{VI} - \overleftarrow{\mathbf{GG}}\right]^{-1} \tag{5-168a}$$

$$\mathbf{RP} = \left[\varepsilon\mathbf{AI}_{2,2} - \overleftarrow{\mathbf{SS}}_{2,2} - \overleftarrow{\mathbf{SG}}_2\cdot\mathbf{PP}\cdot\overleftarrow{\mathbf{GS}}_2\right]^{-1} \tag{5-168b}$$

The emissive power vectors $\mathbf{E}$ and $\mathbf{E}_g$ are then both *known* quantities for purposes of subsequent calculation.

Algebraic Formulas for a Single Gas Zone As shown in Fig. 5-10, the three-zone system with $M = 2$ and $N = 1$ can be employed to simulate a surprisingly large number of useful engineering geometries. These include two infinite parallel plates confining an absorbing-emitting medium; *any* two-surface zone system where a nonconvex surface zone is completely surrounded by a second zone (this includes concentric spheres and cylinders), and the speckled two-surface enclosure. As in the case of a transparent medium, the inverse reflectivity matrix $\mathbf{R}$ is capable of explicit matrix inversion for $M = 2$. This allows derivation of *explicit* algebraic equations for all the required *directed* exchange areas for the clear plus gray WSGG spectral model with $M = 1$ and 2 and $N = 1$.

The Limiting Case M = 1 and N = 1 The directed exchange areas for this special case correspond to a single well-mixed gas zone completely surrounded by a single surface zone A_1. Here the reflectivity matrix is a 1×1 scalar quantity which follows directly from the general matrix equations as $\mathbf{R} = [1/(A_1 - \overline{s_1s_1}\cdot\rho_1)]$. There are *two* WSCC clear plus gray constants a_1 and a_g, and only *one* unique direct exchange area which satisfies the conservation relation $\overline{s_1s_1} + \overline{s_1g} = A_1$. The only two physically meaningful directed exchange areas are those between the surface zone A_1 and the gas zone

$$\overleftarrow{S_1G} = \frac{a_g\cdot\varepsilon_1A_1\cdot\overline{s_1g}}{\varepsilon_1\cdot A_1 + \rho_1\cdot\overline{s_1g}} \tag{5-169a}$$

$$\overleftarrow{GS_1} = \frac{a_1\cdot\varepsilon_1A_1\cdot\overline{s_1g}}{\varepsilon_1\cdot A_1 + \rho_1\cdot\overline{s_1g}} \tag{5-169b}$$

The total radiative flux Q_1 at surface A_1 and the radiative source term $Q_1 = S$ are given by

$$Q_1 = \overleftarrow{GS_1}\cdot E_1 - \overleftarrow{S_1G}\cdot E_g \tag{5-169}$$

Directed Exchange Areas for M = 2 and N = 1 For this case there are *four* WSGG constants, i.e., a_1, a_2, a_g, and τ_g. There is one required value of K that is readily obtained from the equation $K = -\ln(\tau_g)/L_M$, where $\tau_g = \exp(-KL_M)$. For an enclosure with $M = 2$, $N = 1$, and $K \neq 0$, only *three unique* direct exchange areas are required because conservation stipulates $A_1 = \overline{s_1s_2} + \overline{s_1s_2} + \overline{s_1g}$ and $A_2 = \overline{s_1s_2} + \overline{s_2s_2} + \overline{s_2g}$. For $M = 2$ and $N = 1$, the matrix Eqs. (5-118) readily lead to the *general* gray gas matrix solution for $\overline{\mathbf{SS}}$ and $\overline{\mathbf{SG}}$ with $K \neq 0$ as

$$\overline{\mathbf{SS}} = \begin{bmatrix}\varepsilon_1A_1 - \overline{S_1S_2} - \overline{S_1G} & \overline{S_1S_2}\\ \overline{S_1S_1} & \varepsilon_2A_2 - \overline{S_1S_2} - \overline{S_2G}\end{bmatrix} \tag{5-170a}$$

where

$$\overline{S_1S_2} = \varepsilon_1\varepsilon_2A_1A_2\overline{s_1s_2}/\det\mathbf{R}^{-1} \tag{5-170b}$$

and $$\overline{\mathbf{SG}} = \begin{bmatrix}\varepsilon_1A_1[(A_2 - \rho_2\cdot\overline{s_2s_2})\cdot\overline{s_1g} + \rho_2\cdot\overline{s_1s_2}\cdot\overline{s_2g}]\\ \varepsilon_2A_2[(A_1 - \rho_1\cdot\overline{s_1s_1})\cdot\overline{s_2g} + \rho_1\cdot\overline{s_1s_2}\cdot\overline{s_1g}]\end{bmatrix}\Big/\det\mathbf{R}^{-1} \tag{5-170c}$$

with $\overline{\mathbf{GS}} = \overline{\mathbf{SG}}^{\mathrm{T}}$ and the indicated determinate of $\mathbf{R}^{-1}$ is evaluated algebraically as

$$\det\mathbf{R}^{-1} = (A_1 - \overline{s_1s_1}\cdot\rho_1)\cdot(A_2 - \overline{s_2s_2}\cdot\rho_2) - \rho_1\cdot\rho_2\cdot\overline{s_1s_2}^2 \tag{5-170d}$$

For the WSGG clear gas components we denote $\overline{\mathbf{SS}}\,\big]_{K=0} \equiv \overline{\mathbf{SS}}_0$ and $\overline{\mathbf{SG}}\,\big]_{K=0} \equiv \overline{\mathbf{SG}}_0 = \mathbf{0}.$ Finally the WSGG arrays of directed exchange areas are computed simply from a-weighted sums of the gray gas total exchange areas as

$$\overleftarrow{\mathbf{SS}} = \overline{\mathbf{SS}}_0\cdot\begin{bmatrix}1-a_1 & 0\\ 0 & 1-a_2\end{bmatrix} + \overline{\mathbf{SS}}\cdot\begin{bmatrix}a_1 & 0\\ 0 & a_2\end{bmatrix}$$

$$\overleftarrow{\mathbf{SG}} = \overline{\mathbf{SG}}\cdot a_g \tag{5-171a,b,c}$$

$$\overleftarrow{\mathbf{GS}} = \overleftarrow{\mathbf{GS}}\cdot\begin{bmatrix}a_1 & 0\\ 0 & a_2\end{bmatrix} \neq \overleftarrow{\mathbf{SG}}^T$$

and finally

$$\overleftarrow{\mathbf{GG}} = a_g\cdot 4KV - \overleftarrow{\mathbf{GS}}\cdot\begin{bmatrix}1\\ 1\end{bmatrix} \tag{5-171d}$$

The results of this development may be further expanded into algebraic form with the aid of Eq. (5-127) to yield the following

$$\overleftarrow{S_2S_1} = \frac{\varepsilon_1\varepsilon_2A_1A_2\cdot\overline{s_2s_1}]_0(1 - a_1)}{\varepsilon_1\varepsilon_1A_1A_2 + (\varepsilon_1A_1\rho_2 + \varepsilon_2A_2\rho_1)\overline{s_2s_1}]_0} + \frac{\varepsilon_1\varepsilon_2A_1A_2\overline{s_2s_1}\cdot a_1}{\det\mathbf{R}^{-1}} \tag{5-171e}$$

$$\overleftarrow{\mathbf{SG}} = \begin{bmatrix}\varepsilon_1A_1[(A_2 - \rho_2\cdot\overline{s_2s_2})\cdot\overline{s_1g} + \rho_2\cdot\overline{s_1s_2}\cdot\overline{s_2g}]a_g\\ \varepsilon_2A_2[(A_1 - \rho_1\cdot\overline{s_1s_1})\cdot\overline{s_2g} + \rho_1\cdot\overline{s_1s_2}\cdot\overline{s_1g}]a_g\end{bmatrix}\Big/\det\mathbf{R}^{-1} \tag{5-171f}$$

and $$\overleftarrow{\mathbf{GS}} = \left[\overleftarrow{GS_1}\ \ \overleftarrow{GS_2}\right] \tag{5-171g}$$

whose matrix elements are given by $\overleftarrow{GS}_1 \equiv \varepsilon_1 A_1[(A_2 - \rho_2 \cdot \overline{s_1 s_1}) \cdot \overline{s_1 g} + \rho_2 \cdot \overline{s_1 s_2} \cdot \overline{s_2 g}]a_1/\det \mathbf{R}^{-1}$ and $\overleftarrow{GS}_2 \equiv \varepsilon_2 A_2[(A_1 - \rho_1 \cdot \overline{s_1 s_1}) \cdot \overline{s_2 g} + \rho_1 \cdot \overline{s_1 s_2} \cdot \overline{s_1 g}]a_2/\det \mathbf{R}^{-1}$. Derivation of the scalar (algebraic) forms for the directed exchange areas here is done primarily for pedagogical purposes. Computationally, the only advantage is to obviate the need for a digital computer to evaluate a [2 × 2] matrix inverse.

Allowance for an Adiabatic Refractory with N = 1 and M = 2 Put $N = 1$ and $M = 2$, and let zone 2 represent the refractory surface. Let $Q_2 = 0$ and $\varepsilon_2 \neq 0$, and it then follows that we may define a *refractory-aided* directed exchange area $\overleftarrow{S_1 G_R}$ by

$$\overleftarrow{S_1 G_R} = \overleftarrow{S_1 G} + \frac{\overleftarrow{S_1 S_2} \cdot \overleftarrow{S_2 G}}{\overleftarrow{S_1 S_2} + \overleftarrow{S_2 G}} \tag{5-172a}$$

Assuming radiative equilibrium, the emissive power of the refractory may also be calculated from the companion equation

$$E_2 = \frac{\overleftarrow{S_2 S_1} \cdot E_1 + \overleftarrow{S_2 G} \cdot E_g}{\overleftarrow{S_2 S_1} + \overleftarrow{S_2 G}} \tag{5-172b}$$

In this circumstance, *all* the radiant energy originating in the gas volume is transferred to the *sole* sink zone A_1. Equation (5-172*a*) is thus tantamount to the statement that $Q_1 = S'$ or that the net emission from the source ultimately must arrive at the sink. Notice that if $\varepsilon_1 = 0$, Eq. (5-172*a*) leads to a physically incongruous statement since *all* the directed exchange areas would vanish and *no sink* would exist. Even for the simple case of $M = 2, N = 1$, the algebraic complexity of Eqs. (5-171) suggests that *numerical matrix manipulation* of directed exchange areas is to be preferred rather than calculations using algebraic formulas.

Engineering Approximations for Directed Exchange Areas Use of the preceding equations for directed exchange areas with $M = 2$, $N = 1$ and the WSGG clear plus gray gas spectral approximation requires knowledge of three independent direct exchange areas. It also formally requires evaluation of three WSGG weighting constants a_1, a_2, and a_g with respect to the three temperatures T_1, T_2, and T_g. Further simplifications may be made by assuming that radiant transfer for the *entire* enclosure is characterized by the *single* mean beam length $L_M = 0.88 \cdot 4 \cdot V/A$. The requisite direct exchange areas are then approximated by

$$\overline{\mathbf{ss}} = \tau_g \begin{bmatrix} A_1 \cdot F_{1,1} & A_1 \cdot F_{1,2} \\ A_2 \cdot F_{2,1} & A_2 \cdot F_{2,2} \end{bmatrix} \tag{5-173a}$$

with

$$\overline{\mathbf{sg}} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \tag{5-173b}$$

and for the particular case of a speckled enclosure

$$\overline{\mathbf{ss}} = \frac{\tau_g}{A_1 + A_2} \begin{bmatrix} A_1^2 & A_1 \cdot A_2 \\ A_1 \cdot A_2 & A_2^2 \end{bmatrix} \tag{5-174a}$$

also with

$$\overline{\mathbf{sg}} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \tag{5-174b}$$

where again τ_g is obtained from the WSGG fit of gas emissivity. These approximate formulas clearly obviate the need for *exact* values of the direct exchange areas and may be used in conjunction with Eqs. (5-171).

For engineering calculations, an additional simplification is sometimes warranted. Again characterize the system by a single mean beam length $L_M = 0.88 \cdot 4 \cdot V/A$ and employ the *identical* value of $\tau_g = KL_M$ for all surface-gas transfers. The three a constants *might* then be obtained by a WSGG data-fitting procedure for gas emissivity and gas absorptivity which utilizes the three different temperatures T_g, T_1, and T_2. For engineering purposes we choose a simpler method, however. First calculate values of ε_g and α_{g1} for gas temperature T_g with respect to the *dominant* (sink) temperature T_1. The *net* radiative flux between an isothermal gas mass at temperature T_g and a black isothermal bounding surface A_1 at temperature T_1 (the sink) is given by Eq. (5-138) as

$$Q_{1,g} = A_1 \sigma (\alpha_{g,1} T_1^4 - \varepsilon_g T_g^4) \tag{5-175}$$

It is clear that transfer from the gas to the surface and transfer from the surface into the gas are characterized by two different constants of proportionality, ε_g and $\alpha_{g,1}$. To allow for the difference between gas emissivity and absorptivity, it proves convenient to introduce a single *mean gas emissivity* defined by

$$\sigma[\varepsilon_g T_g^4 - \alpha_{g,1} T_1^4] = \varepsilon_m \sigma (T_g^4 - T_1^4) \tag{5-176a}$$

or

$$\varepsilon_m \equiv \frac{\varepsilon_g - \alpha_{g,1}(T_1/T_g)^4}{1 - (T_1/T_g)^4} \tag{5-176b}$$

The calculation then proceeds by computing *two* values of ε_m at the given T_g and T_1 temperature pair and the two values of pL_M and $2pL_M$. We thereby obtain the expression $\varepsilon_m = a_m(1 - \tau_m)$. It is then assumed that $a_1 = a_2 = a_g = a_m$ for use in Eqs. (5-171). This simplification may be used for $M > 2$ as long as $N = 1$. This simplification is illustrated in Example 12.

Example 12: WSGG Clear plus Gray Gas Emissivity Calculations Methane is burned to completion with 20 percent excess air (50 percent relative humidity at 298 K or 0.0088 mol water/mol dry air) in a furnace chamber of floor dimensions 3 × 10 m and height 5 m. The entire surface area of the enclosure is a gray sink with emissivity of 0.8 at temperature 1000 K. The confined gas is well stirred at a temperature of 1500 K. Evaluate the clear plus gray WSGG constants and the mean effective gas emissivity, and calculate the average radiative flux density to the enclosure surface.

Two-zone model, M = 1, N = 1: A single volume zone completely surrounded by a single sink surface zone.

Function definitions:

Gas emissivity: Eq. (5-140*a*) $\quad \varepsilon gF(T_g, pL, b, n) := b \cdot (pL - 0.015)^n \div T_g$

Gas absorptivity: Eq. (5-141) $\quad \alpha g1F(T_g, T_1, pL, b, n)$

$$:= \frac{\varepsilon gF(T_1, pL \cdot T_1 \div T_g, b, n) \cdot T_1 \cdot (T_g \div T_1)^{0.5}}{T_1}$$

Mean effective gas emissivity: Eq. (5-176*a*) $\quad \varepsilon_{gm}(\varepsilon_g, \alpha_g, T_g, T_1) := \dfrac{\varepsilon_g - \alpha_g \cdot (T_1 \div T_g)^4}{1 - (T_1 \div T_g)^4}$

Physical constants: $\quad \sigma \equiv 5.670400 \times 10^{-8} \dfrac{\text{W}}{\text{m}^2 \cdot \text{K}^4}$

Enclosure input parameters:

$T_g := 1500$ K $\quad T_1 := 1000$ K $\quad A_1 := 190$ m^2 $\quad V := 150$ m^3

$\varepsilon_1 := 0.8 \quad \rho_1 := 1 - \varepsilon_1 \quad \rho_1 = 0.2$

$E_1 := \sigma \cdot T_1^4 \quad E_g := \sigma \cdot T_g^4 \quad E_1 = 56.70 \dfrac{\text{kW}}{\text{m}^2} \quad E_g = 287.06 \dfrac{\text{kW}}{\text{m}^2}$

Stoichiometry yields the following mole table:

Mole Table: Basis 1.0 mol Methane

Species	MW	Moles in	Mass in	Moles out	Y out
CH_4	16.04	1.00000	16.04	0.00000	0.00000
O_2	32.00	2.40000	76.80	0.40000	0.03193
N_2	28.01	9.02857	252.93	9.02857	0.72061
CO_2	44.01	0.00000	0.00	1.00000	0.07981
H_2O	18.02	0.10057	1.81	2.10057	0.16765
Totals	27.742	12.52914	347.58	1.52914	1.00000

$p_W := .16765$ atm $\quad p_C := 0.07981$ atm $\quad p := p_W + p_C \quad p = 0.2475$ atm

$p_W \div p_C = 2.101$

The mean beam length is approximated by

$L_M := 0.88 \cdot 4 \cdot V \div A_1 \quad L_M = 2.7789$ m

and $\quad pL_M := p \cdot L_M \quad pL_M = 0.6877$ atm·m $\quad pL_M := 0.6877$

The gas emissivities and absorptivities are then calculated from the two constant correlation in Table 5-5 (column 5 with $p_w/p_c = 2.0$) as follows:

$\varepsilon_{g1} := \varepsilon gF(1500, pL_M, 540, .42) \quad \varepsilon_{g1} = 0.3048$

$\varepsilon_{g2} := \varepsilon gF(1500, 2pL_M, 540, .42)$ $\quad\varepsilon_{g2} = 0.4097$

$\alpha_{g11} := \alpha g1F(1500, 1000, pL_M, 444, .34)$ $\quad\alpha_{g11} = 0.4124$

$\alpha_{g12} := \alpha g1F(1500, 1000, 2pL_M, 444, .34)$ $\quad\alpha_{g12} = 0.5250$

Case (a): Compute Flux Density Using Exact Values of the WSGG Constants

$$\tau_g := \frac{\varepsilon_{g2}}{\varepsilon_{g1}} - 1 \qquad a_g := \frac{\varepsilon_{g1}}{1-\tau_g} \qquad \varepsilon_g := a_g\cdot(1-\tau_g) \qquad a_{g1} := \frac{\alpha_{g11}}{1-\tau_g}$$

$$\tau_g = 0.3442 \qquad a_g = 0.4647 \qquad \varepsilon_g = 0.3048 \qquad a_{g1} = 0.6289$$

and the WSGG gas absorption coefficient (which is necessary for calculation of direct exchange areas) is calculated as $K_1 := \frac{-(\ln \tau_g)}{L_M}$ or $K_1 = 0.3838\ \frac{1}{\text{m}}$

Compute directed exchange areas:
Eqs. (5-169)

$$s1g := (1-\tau_g)\cdot A_1 \qquad s1g = 124.61\ \text{m}^2$$

$$\text{DS1G} := \frac{a_g\cdot\varepsilon_1\cdot A_1\cdot s1g}{\varepsilon_1\cdot A_1 + \rho_1\cdot s1g} \qquad \text{DGS1} := \frac{a_{g1}\cdot\varepsilon_1\cdot A_1\cdot s1g}{\varepsilon_1\cdot A_1 + \rho_1\cdot s1g}$$

$$\text{DS1G} = 49.75\ \text{m}^2 \qquad \text{DGS1} = 67.32\ \text{m}^2$$

And finally the gas to sink flux density is computed as

$$Q_1 := \text{DGS1}\cdot E_1 - \text{DS1G}\cdot E_g \qquad Q_1 = -10464.0\ \text{kW} \qquad \frac{Q_1}{A_1} = -55.07\ \frac{\text{kW}}{\text{m}^2}$$

Case (b): Compute the Flux Density Using Mean Effective Gas Emissivity Approximation

$$\varepsilon_{gm1} := \varepsilon_{gm}(\varepsilon_{g1},\alpha_{g11},T_g,T_1) \qquad \varepsilon_{gm1} = 0.2783$$
$$\varepsilon_{gm2} := \varepsilon_{gm}(\varepsilon_{g2},\alpha_{g12},T_g,T_1) \qquad \varepsilon_{gm2} = 0.3813$$

$$\tau_m := \frac{\varepsilon_{gm2}}{\varepsilon_{gm1}} - 1 \qquad a_m := \frac{\varepsilon_{gm1}}{1-\tau_m} \qquad \varepsilon_{gm} := a_m\cdot(1-\tau_m)$$

$$\tau_m = 0.3701 \qquad a_m = 0.4418 \qquad \varepsilon_{gm} = 0.2783 \qquad s1g_m := (1-\tau_m)\cdot A_1$$

$$\text{S1G}_m := \frac{\varepsilon_1\cdot a_m\cdot s1g_m\cdot A_1}{\varepsilon_1\cdot A_1 + \rho_1\cdot s1g_m)} \qquad \text{S1G}_m = 45.68\ \text{m}^2 \qquad s1g_m = 119.67\ \text{m}^2$$

$$q_{1m} := \frac{\text{S1G}_m\cdot(E_1 - E_g)}{A_1} \qquad q_{1m} = -55.38\ \frac{\text{kW}}{\text{m}^2}$$

$$\text{compared with } \frac{Q_1}{A_1} = -55.07\ \frac{\text{kW}}{\text{m}^2}$$

The computed flux densities are nearly equal because there is a *single* sink zone A_1.

ENGINEERING MODELS FOR FUEL-FIRED FURNACES

Modern digital computation has evolved methodologies for the design and simulation of fuel-fired combustion chambers and furnaces which incorporate virtually *all* the transport phenomena, chemical kinetics, and thermodynamics studied by chemical engineers. Nonetheless, there still exist many furnace design circumstances where such computational sophistication is not always appropriate. Indeed, a practical need still exists for simple engineering models for purposes of conceptual process design, cost estimation, and the correlation of test performance data. In this section, the zone method is used to develop perhaps the simplest **computational template** available to address some of these practical engineering needs.

Input/Output Performance Parameters for Furnace Operation The term **firing density** is typically used to define the basic *operational input parameter* for fuel-fired furnaces. In practice, firing density is often defined as the input fuel feed rate per unit area (or volume) of furnace heat-transfer surface. Thus defined, the firing density is a *dimensional quantity*. Since the feed enthalpy rate $\dot{H}_f$ is proportional to the feed rate, we employ the sink area A_1 to define a **dimensionless firing density** as $N_{FD} = \dot{H}_f/\sigma T_{\text{Ref}}^4\cdot A_1$ where T_{Ref} is some characteristic reference temperature. In practice, gross furnace *output performance* is often described by using one of several *furnace efficiencies*. The most common is the **gas or gas-side furnace efficiency** η_g, defined as the total enthalpy transferred to furnace internals divided by the total available feed enthalpy. Here the total available feed enthalpy is defined to include the lower heating value (LHV) of the fuel plus any air preheat above an arbitrary ambient datum temperature. Under certain conditions the definition of furnace efficiency reduces to some variant of the simple equation $\eta_g = (T_{\text{Ref}} - T_{\text{out}})/(T_{\text{Ref}} - T_0)$ where again T_{Ref} is some reference temperature appropriate to the system in question.

The Long Plug Flow Furnace (LPFF) Model If a combustion chamber of cross-sectional area A_{Duct} and perimeter P_{Duct} is sufficiently long in the direction of flow, compared to its mean hydraulic radius, $L \gg R_h = A_{\text{Duct}}/P_{\text{Duct}}$, the radiative flux from the gas to the bounding surfaces can sometimes be adequately characterized by the *local* gas temperature. The physical rationale for this is that the *magnitudes* of the opposed upstream and downstream radiative fluxes through a cross section transverse to the direction of flow are sufficiently large as to substantially balance each other. Such a situation is not unusual in engineering practice and is referred to as the *long furnace approximation*. As a result, the radiative flux from the gas to the bounding surface may then be approximated using *two-dimensional* directed exchange areas, $\overleftarrow{S_1G}/A_1 \equiv \frac{\partial(\overleftarrow{S_1G})}{\partial A_1}$, calculated using methods as described previously.

Consider a duct of length L and perimeter P, and assume plug flow in the direction of flow z. Further assume high-intensity mixing at the entrance end of the chamber such that combustion is *complete* as the combustion products enter the duct. The duct then acts as a long heat exchanger in which heat is transferred to the walls at constant temperature T_1 by the combined effects of radiation and convection. Subject to the long furnace approximation, a differential energy balance on the duct then yields

$$\dot{m}\overline{C}_p\frac{dT_g}{dz} = P\left[\frac{\overleftarrow{S_1G}}{A_1}\sigma\left(T_g^4 - T_1^4\right) + h(T_g - T_1)\right] \qquad (5\text{-}177)$$

where $\dot{m}$ is the mass flow rate and $\overline{C}_p$ is the heat capacity per unit mass. Equation (5-177) is nonlinear with respect to temperature. To solve Eq. (5-177), first linearize the convective heat-transfer term in the right-hand side with the approximation $\Delta T = T_2 - T_1 \approx (T_2^4 - T_1^4)/4\overline{T}_{1,2}^3$ where $\overline{T}_{1,2} = (T_1 + T_2)/2$. This linearization underestimates ΔT by no more than 5 percent when $T_2/T_1 < 1.59$. Integration of Eq. (5-177) then leads to the solution

$$\ln\left[\frac{(T_{g,\text{out}} - T_1)(T_{g,\text{in}} + T_1)}{(T_{g,\text{out}} + T_1)(T_{g,\text{in}} - T_1)}\right] + 2.0\tan^{-1}\left[\frac{(T_{g,\text{in}} - T_{g,\text{out}})\cdot T_1}{\left(T_1^2 + T_{g,\text{in}}\cdot T_{g,\text{out}}\right)}\right] = -\frac{4}{D_{\text{eff}}} \qquad (5\text{-}178)$$

The LPFF model is described by only two dimensionless parameters, namely an *effective* firing density and a dimensionless sink temperature, viz.,

$$D_{\text{eff}} = \frac{N_{\text{FD}}}{\left(\frac{\overleftarrow{S_1G}}{A_1}\right) + N_{\text{CR}}} \quad \text{and} \quad \Theta_1 = T_1/T_{g,\text{in}} \qquad (5\text{-}178a,b)$$

Here the dimensionless firing density, N_{FD}, and a dimensionless convection-radiation number N_{CR} are defined as

$$N_{\text{FD}} = \frac{\dot{m}\,\overline{C}_p}{\sigma\cdot T_1^3 A_1} \quad \text{and} \quad N_{\text{CR}} = \frac{h}{4\sigma\overline{T}_{g,1}^3} \qquad (5\text{-}178c,d)$$

where $A_1 = PL$ is the duct surface area (the sink area), and $\overline{T}_{g,1} = (\overline{T}_g + T_1)/2$ is treated as a constant. This definition of the effective dimensionless firing density, D_{eff}, clearly delineates the relative

roles of radiation and convective heat transfer since radiation and convection are identified as *parallel* (*electrical*) *conductances*.

In analogy with a conventional heat exchanger, Eq. (5-178) displays two asymptotic limits. First define

$$\eta_f = \frac{T_{g,in} - T_{g,out}}{T_{g,in} - T_1} = 1 - \frac{T_{g,out} - T_1}{T_{g,in} - T_1} \tag{5-179}$$

as the efficiency of the long furnace. The two asymptotic limits with respect to firing density are then given by

$$D_{eff} \ll 1, \qquad T_{g,out} \to T_1 \qquad \eta_f \to 1 \tag{5-179a}$$

and

$$D_{eff} \gg 1, \qquad T_{g,out} \to T_{g,in}$$

$$\eta_f \to \frac{4}{D_{eff}\left[1 - \dfrac{R-1}{R+1} - 2\,\dfrac{R-1}{R^2+1}\right]} \tag{5-179b}$$

where $R \equiv T_{g,in}/T_1 = 1/\Theta_1$.

For low firing rates, the exit temperature of the furnace gases approaches that of the sink; i.e., sufficient residence time is provided for nearly complete heat removal from the gases. When the combustion chamber is overfired, only a small fraction of the available feed enthalpy heat is removed within the furnace. The exit gas temperature then remains essentially that of the inlet temperature, and the furnace efficiency tends asymptotically to zero.

It is important to recognize that the two-dimensional exchange area $\dfrac{\overleftarrow{S_1G}}{A_1} \equiv \dfrac{\partial(\overleftarrow{S_1G})}{\partial A_1}$ in the definition of D_{eff} can represent a *lumped* two-dimensional exchange area of somewhat arbitrary complexity. This quantity also contains *all* the information concerning furnace geometry and gas and surface emissivities. To compare the relative importance of radiation with respect to convection, suppose $h = 10$ Btu/(hr·ft²·°R) = 0.057 kW/(K·m²) and $\overline{T}_{g,1} = 1250$ K, which leads to the numerical value $N_{CR} = 0.128$; or, in general, N_{CR} is of order 0.1 or less. The importance of the radiation contribution is estimated by bounding the magnitude of the dimensionless directed exchange area. For the case of a single gas zone completely surrounded by a black enclosure, Eq. (5-169) reduces to simply $\overleftarrow{S_1G}/A_1 = \varepsilon_g \le 1.0$, and it is evident that the magnitude of the radiation contribution never exceeds unity. At high temperatures, radiative effects can easily dominate other modes of heat transfer by an order of magnitude or more. When mean beam length calculations are employed, use $L_M/D = 0.94$ for a cylindrical cross section of diameter D, and

$$L_{M0} = \frac{2H \cdot W}{H + W}$$

for a rectangular duct of height H and width W.

The Well-Stirred Combustion Chamber (WSCC) Model Many combustion chambers utilize high-momentum feed conditions with associated high-intensity mixing. The **well-stirred combustion chamber (WSCC) model** assumes a single gas zone and high-intensity mixing. Moreover, combustion and heat transfer are visualized to occur *simultaneously* within the combustion chamber. The WSCC model is characterized by some *six* temperatures which are listed in rank order as T_0, T_{air}, T_1, T_e, T_g, and T_f. Even though the combustion chamber is well mixed, it is *arbitrarily* assumed that the gas temperature within the enclosure T_g is *not necessarily equal* to the gas exit temperature T_e. Rather the two temperatures are related by the simple relation $\Delta T_{ge} \equiv T_g - T_e$, where $\Delta T_{ge} \approx 170$ K (as a representative value) is introduced as an *adjustable parameter* for purposes of data fitting and to make allowance for nonideal mixing. In addition, T_0 is the ambient temperature, T_{air} is the air preheat temperature, and T_f is a *pseudoadiabatic flame temperature*, as shall be explained in the following development. The condition $\Delta T_{ge} \equiv 0$ is intended to simulate a perfect continuous well-stirred reactor (CSTR).

Dimensional WSCC Approach A macroscopic enthalpy balance on the well-stirred combustion chamber is written as

$$-\Delta H = H_{In} - H_{Out} = Q_{Rad} + Q_{Con} + Q_{Ref} \tag{5-180}$$

Here $Q_{Rad} = \overleftarrow{S_1G_R}\sigma(T_g^4 - T_1^4)$ represents radiative heat transfer to the sink (with due allowance for the presence of any refractory surfaces). And the two terms $Q_{Con} = h_1A_1(T_g - T_1)$ and $Q_{Ref} = UA_R(T_g - T_0)$ formulate the convective heat transfer to the sink and *through* the refractory, respectively.

Formulation of the left-hand side of Eq. (5-180) requires representative thermodynamic data and information on the combustion stoichiometry. In particular, the former includes the lower heating value of the fuel, the temperature-dependent molal heat capacity of the inlet and outlet streams, and the air preheat temperature T_{air}. It proves especially convenient now to introduce the definition of a pseudoadiabatic flame temperature T_f, which is *not* the true adiabatic flame temperature, but rather is an adiabatic flame temperature based on the average heat capacity of the combustion products over the temperature interval $T_0 < T < T_e$. The calculation of T_f does not allow for dissociation of chemical species and is a surrogate for the total enthalpy content of the input fuel-air mixture. It also proves to be an especially convenient system *reference temperature*. Details for the calculation of T_f are illustrated in Example 13.

In terms of this particular definition of the pseudoadiabatic flame temperature T_f, the total enthalpy change and gas efficiency are given simply as

$$\Delta H = \dot{H}_f - \dot{m}\cdot\overline{C}_{P,Prod}(T_e - T_0) = \dot{m}\overline{C}_{P,Prod}(T_f - T_e) \tag{5-181a,b}$$

where $\dot{H}_f \equiv \dot{m}\cdot\overline{C}_{p,Prod}(T_f - T_0)$ and $T_e = T_g - \Delta T_{ge}$. This particular definition of T_f leads to an especially convenient formulation of furnace efficiency

$$\eta_g = Q/\dot{H}_f = \frac{\dot{m}\cdot\overline{C}_{P,Prod}(T_f - T_e)}{\dot{m}\cdot\overline{C}_{P,Prod}(T_f - T_0)} = \frac{T_f - T_e}{T_f - T_0} \tag{5-182}$$

In Eq. (5-182), $\dot{m}$ is the total mass flow rate and $\overline{C}_{P,Prod}$ [J/(kg·K)] is defined as the average heat capacity of the product stream over the temperature interval $T_0 < T < T_e$.

The final overall enthalpy balance is then written as

$$\dot{m}\cdot\overline{C}_{P,Prod}(T_f - T_e) = \overleftarrow{S_1G_R}\,\sigma\left(T_g^4 - T_1^4\right) + h_1A_1(T_g - T_1) + UA_R(T_g - T_0) \tag{5-183}$$

with $T_e = T_g - \Delta T_{ge}$.

Equation (5-183) is a nonlinear algebraic equation which may be solved by a variety of iterative methods. The *sole* unknown quantity, however, in Eq. (5-183) is the gas temperature T_g. It should be recognized, in particular, that T_f, T_e, $\overline{C}_{P,Prod}$, and the directed exchange area are all explicit functions of T_g. The method of solution of Eq. (5-183) is demonstrated in some detail in Example 13.

Dimensionless WSCC Approach In Eq. (5-183), assume the convective heat loss through the refractory is negligible, and linearize the convective heat transfer to the sink. These approximations lead to the result

$$\dot{m}\cdot\overline{C}_{P,Prod}(T_f - T_g + \Delta T_{ge}) = \overleftarrow{S_1G_R}\,\sigma\left(T_g^4 - T_1^4\right) + h_1A_1\left(T_g^4 - T_1^4\right)/4\overline{T}_{g,1}^3 \tag{5-184}$$

where $\overline{T}_{g,1} = (T_g + T_1)/2$ is some characteristic average temperature which is taken as constant. Now normalize all temperatures based on the pseudoadiabatic temperature as in $\Theta_i = T_i/T_f$. Equation (5-184) then leads to the dimensionless equation

$$D_{eff}(1 - \Theta_g + \Delta^*) = \left(\Theta_g^4 - \Theta_1^4\right) \tag{5-185}$$

where again $D_{eff} = N_{FD}/\left(\overleftarrow{S_1G}/A_1 + N_{CR}\right)$ is defined *exactly* as in the case of the LPFF model, with the proviso that the WSCC dimensionless firing density is defined here as $N_{FD} = \dot{m}\overline{C}_{P,Prod}/(\sigma\ T_f^3 \cdot A_1)$. The dimensionless furnace efficiency follows directly from Eq. (5-182) as

$$\eta_g = \frac{1 - \Theta_e}{1 - \Theta_0} = \frac{1 - \Theta_g + \Delta^*}{1 - \Theta_0} \tag{5-186a}$$

We also define a **reduced furnace efficiency** η'_g

$$\eta'_g \equiv (1 - \Theta_0)\eta_g = 1 - \Theta_g + \Delta^* \tag{5-186b}$$

Since Eq. (5-186*b*) may be rewritten as $\Theta_g = (1 + \Delta^* - \eta'_g)$, combination of Eqs. (5-185) and (5-186*b*) then yields the final result

$$D_{\text{eff}}\eta'_g = (1 + \Delta^* - \eta'_g)^4 - \Theta_1^4 \tag{5-187}$$

Equation (5-187) provides an *explicit* relation between the modified furnace efficiency and the effective firing density directly in which the gas temperature is eliminated.

Equation (5-187) has two asymptotic limits

$$D_{\text{eff}} << 1 \qquad \Theta_g \to \Theta_1$$
$$\eta'_g \to 1 - \Theta_1 + \Delta^* \tag{5-188a}$$

and

$$D_{\text{eff}} >> 1 \qquad \Theta_g \to 1 + \Delta^* \qquad \text{and} \qquad \Theta_e \to 1$$

$$\eta'_g \to \frac{(1+\Delta^*)^4 - \Theta_1^4}{D_{\text{eff}} + 4(1+\Delta^*)^3} \tag{5-188b}$$

Figure 5-23 is a plot of η'_g versus D_{eff} computed from Eq. (5-187) for the case $\Delta^* = 0$.

The asymptotic behavior of Eq. (5-189) mirrors that of the LPFF model. Here, however, for low firing densities, the exit temperature of the furnace exit gases approaches $\Theta_e = \Theta_1 - \Delta^*$ rather than the sink temperature. Moreover, for $D_{\text{eff}} << 1$ the reduced furnace efficiency adopts the constant value $\eta'_g = 1 - \Theta_e = 1 + \Delta^* - \Theta_1$. Again at very high firing rates, only a very small fraction of the available feed enthalpy heat is recovered within the furnace. Thus the exit gas temperature remains nearly unchanged from the pseudoadiabatic flame temperature $[T_e \approx T_f,]$ and the gas-side efficiency necessarily approaches zero.

Example 13: WSCC Furnace Model Calculations Consider the furnace geometry and combustion stoichiometry described in Example 12. The end-fired furnace is 3 m wide, 5 m tall, and 10 m long. Methane at a firing rate of 2500 kg/h is burned to completion with 20 percent excess air which is preheated to 600°C. The speckled furnace model is to be used. The sink (zone 1) occupies 60 percent of the total interior furnace area and is covered with two rows of 5-in (0.127-m) tubes mounted on equilateral centers with a center-to-center distance of twice the tube diameter. The sink temperature is 1000 K, and the tube emissivity is 0.7. Combustion products discharge from a 10-m² duct in the roof which is also tube-screen covered and is to be considered part of the sink. The refractory (zone 2) with emissivity 0.6 is radiatively adiabatic but demonstrates a small convective heat loss to be calculated with an overall heat transfer coefficient *U*. Compute all unknown furnace temperatures, the gas-side furnace efficiency, and the mean heat flux density through the tube surface. Use the *dimensional* solution approach for the well-stirred combustor model and compare computed results with the *dimensionless* WSCC and LPFF models. Computed values for mean equivalent gas emissivity obtained from Eq. (5-174*b*) and Table 5-5 for $T_g = 2000$ K for $L_M = 2.7789$ m and $T_1 = 1000$ K are found to be

$$T_g = 1500\text{ K} \qquad a_m = 0.44181 \qquad \tau_m = 0.37014 \qquad \varepsilon_m = 0.27828$$

$$T_g = 2000\text{ K} \qquad a_m = 0.38435 \qquad \tau_m = 0.41844 \qquad \varepsilon_m = 0.22352$$

Over this temperature range the gas emissivity may be calculated by linear interpolation. Additional heat-transfer and thermodynamic data are supplied in context.

Three-zone speckled furnace model, M = 2, N = 1:
Zone 1: Sink (60 percent of total furnace area)
Zone 2: Refractory surface (40 percent of total furnace area)
Physical constants:

$$\sigma \equiv 5.670400 \times 10^{-8}\,\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}$$

Linear interpolation function for mean effective gas emissivity constants:

$$\text{LINTF}(T, Y2, Y1) := \frac{Y1\cdot(2000\text{ K} - T) + Y2\cdot(T - 1500\text{ K})}{500\text{ K}} \quad (1500\text{ K} < T < 2000\text{ K})$$

Enclosure input parameters:

$$V_{\text{tot}} := 150\text{ m}^3 \quad A_{\text{tot}} := 190\text{ m}^2 \quad C_1 := 0.6 \quad C_2 := 1 - C_1$$

$$A_1 := C_1\cdot A_{\text{tot}} \quad A_2 := C_2\cdot A_{\text{tot}} \quad D_{\text{tube}} := .127\text{ m}$$

Direct exchange areas for WSGG clear gas component (temperature independent):

$$F := \begin{pmatrix} C_1 & C_2 \\ C_1 & C_2 \end{pmatrix} \quad AI := \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} \quad ss1 := AI\cdot F \quad ss1 = \begin{pmatrix} 68.40 & 45.60 \\ 45.60 & 30.40 \end{pmatrix}\text{m}^2$$

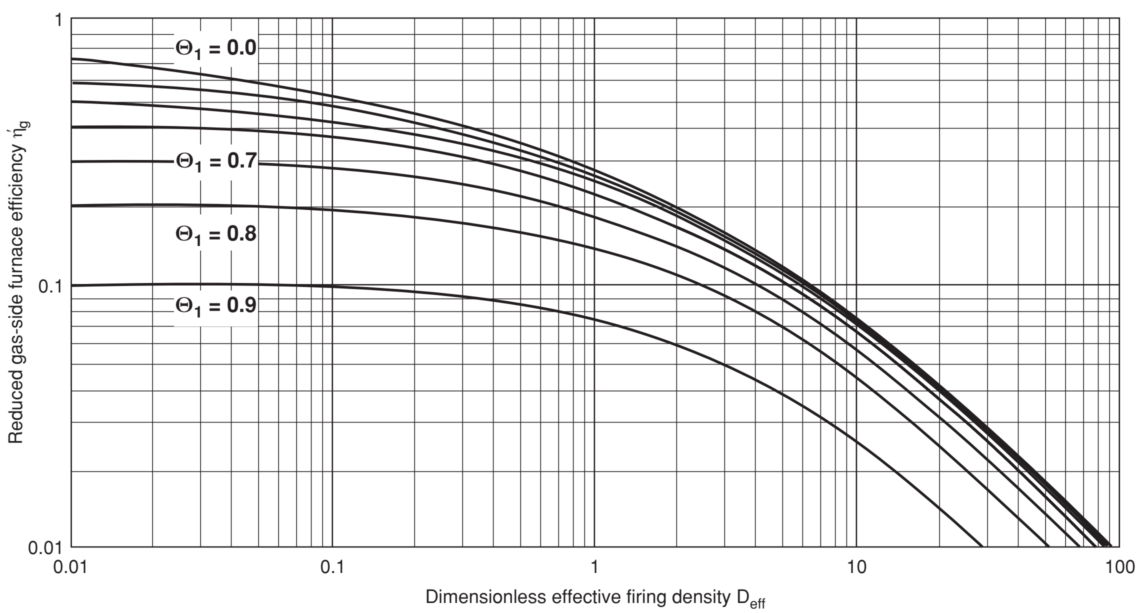

FIG. 5-23 Reduced gas-side furnace efficiency versus effective firing density for well-stirred combustion chamber model. $\Delta^* = 0$, $\Theta_1 = 0.0, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9$.

Equivalent gray plane emissivity calculations for sink:

$\varepsilon_{tube} := 0.7 \quad F_{bar} := 0.987$ (from Fig. 5-13, curve 6 with ratio = 2.0)

$$\varepsilon 1_{eq} := \frac{1}{\left(\frac{1}{1}-1\right)+2\cdot\frac{D_{tube}}{2\cdot\pi\cdot D_{tube}}\cdot\left(\frac{1}{\varepsilon_{tube}}-1\right)+\frac{1}{F_{bar}}} \qquad \varepsilon 1_{eq} = 0.86988$$

$$\varepsilon_1 := \varepsilon 1_{eq} \quad \varepsilon_2 := 0.6 \quad \varepsilon I := \begin{pmatrix} \varepsilon_1 & 0 \\ 0 & \varepsilon_2 \end{pmatrix} \quad \rho I := \text{identity}(2) - \varepsilon I$$

Total exchange areas for WSGG clear gas component:

$$R1 := (AI - ss1\cdot\rho I)^{-1} \quad SS1 := \varepsilon I\cdot AI\cdot R1\cdot ss1\cdot\varepsilon I \quad SS1 = \begin{pmatrix} 67.93 & 31.24 \\ 31.24 & 14.36 \end{pmatrix} \text{m}^2$$

Temperature and emissive power input data:

$$T_1 := 1000.0\text{ K} \qquad T_{air} := 873.15\text{ K}$$

$$T_0 := 298.15\text{ K} \qquad \Delta T_{ge} := 170\text{ K} \quad E_1 := \sigma\cdot T_1^{\,4} \qquad E_1 = 56.704\ \frac{\text{kW}}{\text{m}^2}$$

Mean beam length calculations:

$$L_{M0} := 4\cdot\frac{V_{tot}}{A_{tot}} \quad L_{M0} = 3.1579\text{ m} \quad L_M := 0.88 L_{M0} \quad L_M = 2.7789\text{ m}$$

Stoichiometric and thermodynamic input data:

$$\text{MCH4}_{dot} := 2500\,\frac{\text{kg}}{\text{h}} \quad \text{MW}_{CH4} := 16.04\,\frac{\text{g}}{\text{mol}} \quad \text{MW}_{in} := 27.742\,\frac{\text{g}}{\text{mol}}$$

$$\sum\text{Mols} := 12.52914 \quad \text{LHV} := 191760\,\frac{\text{cal}}{\text{mol}} \quad \text{MCp}_{air} := 7.31\,\frac{\text{cal}}{\text{mol}\cdot\text{K}}$$

$$\text{MCp(T)} := \left[7.01 + 0.875\left(\frac{T}{1000\text{ K}}\right)\right]\frac{\text{cal}}{\text{mol}\cdot\text{K}} \qquad (800\text{ K} < T < 1200\text{ K})$$

M_{dot} is the total mass flowrate and NCH4_{dot} is the molal flowrate of CH_4.

$$M_{dot} := \frac{\text{MCH4}_{dot}\cdot\text{MW}_{in}\cdot\Sigma\text{Mols}}{\text{MW}_{CH4}} \qquad \text{NCH4}_{dot} := \frac{\text{MCH4}_{dot}}{\text{MW}_{CH4}}$$

$$M_{dot} = 54174.5\,\frac{\text{kg}}{\text{h}} \quad \text{NCH4}_{dot} = 155860.3\,\frac{\text{mol}}{\text{h}}$$

Overall refractory heat-transfer coefficient:

$$D_r := 0.343\text{ m} \quad k_r := 0.00050\,\frac{\text{kW}}{\text{m}\cdot\text{K}}$$

$$h_0 := 0.0114\cdot\frac{\text{kW}}{\text{m}^2\cdot\text{K}} \quad h_0 = 2.0077\ \frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\text{R}} \quad h_1 := 0.0170\,\frac{\text{kW}}{\text{m}^2\cdot\text{K}}$$

$$h_1 = 2.9939\,\frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\text{R}} \qquad U := \frac{1}{\frac{1}{h_0}+\frac{1}{h_1}+\frac{D_r}{k_r}}$$

$$U = 0.001201\,\frac{\text{kW}}{\text{m}^2\cdot\text{K}} \qquad U = 0.2115\,\frac{\text{Btu}}{\text{h}\cdot\text{ft}^2\text{R}}$$

START OF ITERATION LOOP: Successive Substitution with T_g as the Trial Variable

$$\text{Assume } T_g := 1759.1633222447\text{ K} \qquad T_e := T_g - \Delta T_{ge} \qquad T_e = 1589.2\text{ K}$$

$$E_g := \sigma\cdot T_g^{\,4} \qquad E_g = 543.05\,\frac{\text{kW}}{\text{m}^2}$$

Compute temperature-dependent mean effective gas emissivity via linear interpolation:

$$\tau_m := \text{LINTF}(T_g, 0.37014, 0.418442) \quad a_m := \text{LINTF}(T_g, 0.44181, 0.38435)$$

$$\tau_m = 0.3934 \qquad a_m = 0.4141 \qquad \varepsilon_m := a_m\cdot(1-\tau_m) \qquad \varepsilon_m = 0.2512$$

Compare interpolated value:

$$\varepsilon_{com} := \text{LINTF}(T_g, 0.27828, 0.22352) \qquad \varepsilon_{com} = 0.2519$$

Direct and total exchange areas for WSGG gray gas component:

$$ss2 := \tau_m\cdot ss1 \qquad sg2 := (\text{AI} - ss2)\begin{bmatrix}1\\1\end{bmatrix} \quad R2 := (AI - ss2\cdot\rho I)^{-1}$$

$$ss2 = \begin{pmatrix} 26.91 & 17.94 \\ 17.94 & 11.96 \end{pmatrix}\text{m}^2 \qquad sg2 = \begin{pmatrix} 69.15 \\ 46.10 \end{pmatrix}\text{m}^2 \qquad SS2 := \varepsilon I\cdot AI\cdot R2\cdot ss2\cdot\varepsilon I$$

Compute directed exchange areas:

$$\text{DSS} := (1-a_m)\cdot SS1 + a_m\cdot SS2 \qquad \text{DSG} := a_m\cdot\varepsilon\text{I}\cdot\text{AI}\cdot R2\cdot sg2$$

Refractory augmented directed gas-sink exchange area:

$$\text{DS1GR} := \text{DSG}_1 + \frac{\text{DSS}_{1,2}\cdot\text{DSG}_2}{\text{DSS}_{1,2}+\text{DSG}_2} \qquad \text{DS1GR} = 35.59\text{ m}^2 \quad \text{Eq. (5-172}a\text{)}$$

Compute refractory temperature (T_2); assume radiative equilibrium:

$$\text{Equation (5-172}b\text{)}:\quad E_2 := \frac{\text{DSS}_{2,1}\cdot E_1 + \text{DSG}_2\cdot E_g}{\text{DSS}_{2,1}+\text{DSG}_2}$$

$$E_2 = 231.24\,\frac{\text{kW}}{\text{m}^2}$$

$$T_2 := \left(\frac{E_2}{\sigma}\right)^{0.25} \qquad T_2 = 1421.1\text{ K}$$

Enthalpy balance: Basis: 1 mole CH_4:

$$h_{in} := LHV + (\Sigma\text{Mols} - 1)\cdot\text{MCp}_{air}\cdot(T_{air}-T_0) \qquad h_{in} = 240219.9\,\frac{\text{cal}}{\text{mol}}$$

Compute pseudoadiabatic flame temperature T_f:

$$T_f := T_0 + \frac{h_{in}}{\Sigma\text{Mols MCp}(T_e)} \qquad h_{out} := \Sigma\text{Mols}\cdot\text{MCp}(T_e)\cdot(T_e - T_0)$$

$$T_f = 2580.5\text{ K} \qquad h_{out} = 135880.8\,\frac{\text{cal}}{\text{mol}}$$

$$H_{in} := \text{NCH4}_{dot}\cdot h_{in} \qquad H_{out} := \text{NCH4}_{dot}\cdot h_{out} \quad \Delta H := H_{out} - H_{in}$$

$$H_{in} = 43543.59\text{ kW} \qquad H_{out} = 24630.51\text{ kW} \quad \Delta H = -18913.08\text{ kW}$$

Overall enthalpy balance:

$$Q1_g := \text{DS1GR}\cdot(E_g - E_1) \qquad Q1_g = 17308.45\text{ kW}$$

$$Q1_{Con} := h_1\cdot A_1\cdot(T_g - T_1) \qquad Q1_{Con} = 1471.26\text{ kW}$$

$$Q2_{Con} := U\cdot A_2\cdot(T_g - T_0) \qquad Q2_{Con} = 133.37\text{ kW}$$

$$\text{ERROR} := Q1_g + Q1_{Con} + Q2_{Con} + \Delta H \qquad \%\text{ERROR1} := 100\,\frac{\text{ERROR}}{\Delta H}$$

$$\text{ERROR} = -0.0000\text{ kW} \qquad \%\text{ERROR1} = 0.00000$$

$$T_{gcalc} := \left[\frac{\text{DS1GR}\cdot E_1 - (\Delta H + Q1_{Con} + Q2_{Con})}{\text{DS1GR}\cdot\sigma}\right]^{0.25} \qquad T_{gcalc} = 1759.16332\text{ K}$$

Average assumed and calculated temperatures for next iteration

$$T_{gnew} := \frac{T_g + T_{gcalc}}{2} \qquad T_{gnew} = 1759.1633222935\text{ K} \qquad \text{Go to Start}$$

END OF ITERATION LOOP: Final Gas Temperature $T_g = 1759.16$ K

$$\eta_g := \frac{H_{in} - H_{out}}{H_{in}} \quad \text{or} \quad \eta 1_g := \frac{T_f - T_e}{T_f - T_0} \quad \eta_g = 0.43435 \quad \eta 1_g = 0.43435$$

Heat flux density calculations:

$$q_1 := \frac{Q1_g + Q1_{Con}}{A_1} \qquad q_{tube} := q_1\cdot\left(2\cdot\frac{D_{tube}}{2\cdot\pi\cdot D_{tube}}\right)$$

$$q_1 = 164.7\,\frac{\text{kW}}{\text{m}^2} \qquad q_{tube} = 52.44\,\frac{\text{kW}}{\text{m}^2}$$

Note: This example was also solved with $\Delta T_{ge} = 0$. The results were as follows: $T_f = 2552.8$ K, $T_g = T_e = 1707.1$ K, $T_2 = 1381.1$ K, $\eta_g = 37.51$ percent, $D_{eff} = 0.53371$, and $\Delta H = 16332.7$ kW. The WSCC model with $\Delta T_{ge} = 0$ predicts a lower performance bound.

Compare dimensionless WSCC model:

$$\Theta_0 := \frac{T_0}{T_f} \quad \Theta_1 := \frac{T_1}{T_f} \quad \Delta T_{star} := \frac{\Delta T_{ge}}{T_f}$$

$$T_{g1} := \frac{T_1 + T_g}{2}$$

$$\Theta_0 = 0.1155 \quad \Theta_1 = 0.3875 \quad \Delta T_{star} = 0.06588 \quad T_{g1} = 1379.58\ \text{K}$$

$$Cp_{Prod} := \frac{MCp(T_e)}{MW_{in}} \qquad Cp_{Prod} = 0.000352\ \text{kW}\cdot\frac{\text{h}}{\text{kg}\cdot\text{K}}$$

$$N_{FD} := M_{dot}\cdot\frac{Cp_{prod}}{\sigma\cdot T_f^3\cdot A_1} \qquad N_{CR} := \frac{h_1}{4\cdot\sigma\cdot T_{g1}^{\ 3}} \qquad D_{eff} := \frac{N_{FD}}{\dfrac{DS1GR}{A_1} + N_{CR}}$$

$$N_{FD} = 0.17176 \quad N_{CR} = 0.02855 \quad D_{eff} = 0.50409 \quad \frac{DS1GR}{A_1} = 0.31218$$

$$\eta_{prime} := \eta_g\cdot(1-\Theta_0) \qquad D1_{eff} := \frac{(1+\Delta T_{star}-\eta_{prime})^4 - \Theta_1^{\ 4}}{\eta_{prime}}$$

$$D1_{eff} = 0.50350 \quad \text{versus} \quad D_{eff} = 0.50409$$

This small discrepancy is due to linearization and neglect of convective refractory heat losses in the dimensionless WSCC model.

Compare dimensionless LPFF model:

$$R_{in} := \frac{1}{\Theta_1} \qquad R_{in} = 2.58050$$

Trial and error calculation to match effective firing densities:
Assume:

$$T_{out} := 1000.13763\ \text{K} \quad R_{out} := \frac{T_{out}}{T_1} \quad R_{out} = 1.00014 \quad \frac{4}{D_{eff}} = 7.93513$$

$$CLong := -\ln\left[\frac{(R_{out}-1)\cdot(R_{in}+1)}{(R_{in}-1)\cdot(R_{out}+1)}\right] - 2\cdot\text{atan}\left(\frac{R_{in}-R_{out}}{1+R_{in}\cdot R_{out}}\right) \quad CLong = 7.93514$$

$$\eta L_f := \frac{R_{in}-R_{out}}{R_{in}-1} \qquad \eta L_f = 0.99991292 \quad \text{versus} \quad \eta_g = 0.43435$$

Note: The long plug flow furnace Model is so efficient that it would be grossly underfired using the computed WSCC effective firing density. Of the two models, the LPFF model always predicts an upper theoretical performance limit.

(This example was developed as a MATHCAD 14® worksheet. Mathcad is registered trademark of Parametric Technology Corporation.)

WSCC Model Utility and More Complex Zoning Models Despite its simplicity, the WSCC construct has a wide variety of practical uses and is of significant pedagogical value. Here an engineering situation of inordinate complexity is described by the definition of only eight dimensionless quantities D_{eff}, N_{FD}, $\overleftarrow{S_1G_R}/A_1$, N_{CR}, η_g, Δ^*, Θ_0, and Θ_1. The first three are related by the simple algebraic definition $D_{eff} = N_{FD}/(\overleftarrow{S_1G_R}/A_1 + N_{CR})$. These dimensionless quantities contain all the physical input information for the model, namely, furnace parameters and geometry, radiative properties of the combustion products, and the stoichiometry and thermodynamics of the combustion process. The WSCC model leads to a dimensionless two-dimensional plot of *reduced* effective furnace efficiency versus dimensionless effective firing density (Fig. 5-23), which is characterized by only two additional parameters, namely, Δ^* and Θ_1.

Of the models presented here, the WSCC model with $\Delta T_{ge} = 0$ produces the lowest furnace efficiencies. The long furnace model usually produces the highest furnace efficiency. This is really not a fair statement because two distinctly different pieces of process equipment are compared. In this regard, a more appropriate definition of the dimensionless firing density for the LPFF model might be $N'_{FD} = \dot{m}\,\overline{C}_p/(\sigma\cdot T^3_{g,in}\cdot A_1)$. It may be counterintuitive, but the WSCC and LPFF models *generally do not* characterize the extreme conditions for the performance of combustors as in the case of chemical reactors.

Figure 5-23 has been used to correlate furnace performance data for a multitude of industrial furnaces and combustors. Typical operational domains for a variety of fuel-fired industrial furnaces are summarized in Table 5-7. The WSCC approach (or "speckled" furnace model) is a classic contribution to furnace design methodology which was first due to Hottel [op. cit.]. The WSCC model provides a simple *furnace design template* which leads to a host of more complex furnace models. These models include an obvious extension to a tanks-in-series model as well as multizone models utilizing empirical cold-flow velocity patterns. For more information on practical furnace design models, reference is made to Hottel and Sarofim (op. cit., Chap. 14). Qualitative aspects of process equipment have been treated in some detail elsewhere (Baukal, C. E., ed., *The John Zink Combustion Handbook,* CRC Press, Boca Raton, Fla., 2001).

TABLE 5-7 Operational Domains for Representative Process Furnaces and Combustors

Domain	Furnace or combustor type	Dimensionless sink temperature	Dimensionless firing density
A	Oil processing furnaces; radiant section of oil tube stills and cracking coils	$\Theta_1 \approx 0.4$	$0.1 < D_{eff} < 1.0$
B	Domestic boiler combustion chambers	$\Theta_1 \approx 0.2$	$0.5 < D_{eff} < 1.1$
C	Glass furnaces	$0.7 < \Theta_1 < 0.8$	$0.035 < D_{eff} < 0.8$
D	Soaking pits	$\Theta_1 \approx 0.6$	$0.7 < D_{eff} < 1.1$
E	Gas-turbine combustors	$0.4 < \Theta_1 < 0.7$	$4.0 < D_{eff} < 25.0$

INTRODUCTION

This part of Sec. 5 provides a concise guide to solving problems in situations commonly encountered by chemical engineers. It deals with diffusivity and mass-transfer coefficient estimation and common flux equations, although material balances are also presented in typical coordinate systems to permit a wide range of problems to be formulated and solved.

Mass-transfer calculations involve transport properties, such as diffusivities, and other empirical factors that have been found to relate mass-transfer rates to measured "driving forces" in myriad geometries and conditions. The context of the problem dictates whether the fundamental or more applied coefficient should be used. One key distinction is that, whenever there is flow parallel to an interface through which mass transfer occurs, the relevant coefficient is an empirical combination of properties and conditions. Conversely, when diffusion occurs in stagnant media or in creeping flow without transverse velocity gradients, ordinary diffusivities may be suitable for solving the problem. In either case, it is strongly suggested to employ data, whenever available, instead of relying on correlations.

Units employed in diffusivity correlations commonly followed the cgs system. Similarly, correlations for mass transfer correlations used the cgs or English system. In both cases, only the most recent correlations employ SI units. Since most correlations involve other properties and physical parameters, often with mixed units, they are repeated here as originally stated. Common conversion factors are listed in Table 1-4.

Fick's First Law This law relates flux of a component to its composition gradient, employing a constant of proportionality called a diffusivity. It can be written in several forms, depending on the units and frame of reference. Three that are related but not identical are

$$ {}_VJ_A = -D_{AB}\frac{dc_A}{dz} \approx {}_MJ_A = -cD_{AB}\frac{dx_A}{dz} \propto {}_mJ_A = -\rho D_{AB}\frac{dw_A}{dz} \quad (5\text{-}189)$$

The first equality (on the left-hand side) corresponds to the molar flux with respect to the volume average velocity, while the equality in the center represents the molar flux with respect to the molar average velocity and the one on the right is the mass flux with respect to the mass average velocity. These must be used with consistent flux expressions for fixed coordinates and for N_C components, such as:

$$N_A = {}_VJ_A + c_A\sum_{i=1}^{N_C} N_i\overline{V}_i = {}_MJ_A + x_A\sum_{i=1}^{N_C} N_i = \frac{{}_mJ_A + w_A\sum_{i=1}^{N_C} n_i}{M_A} \quad (5\text{-}190)$$

In each case, the term containing the summation accounts for *conveyance*, which is the amount of component A carried by the net flow in the direction of diffusion. Its impact on the total flux can be as much as 10 percent. In most cases it is much less, and it is frequently ignored. Some people refer to this as the "convective" term, but that conflicts with the other sense of convection which is promoted by flow perpendicular to the direction of flux.

Mutual Diffusivity, Mass Diffusivity, Interdiffusion Coefficient **Diffusivity** is denoted by D_{AB} and is defined by Fick's first law as the ratio of the flux to the concentration gradient, as in Eq. (5-189). It is analogous to the thermal diffusivity in Fourier's law and to the kinematic viscosity in Newton's law. These analogies are flawed because both heat and momentum are conveniently defined with respect to fixed coordinates, irrespective of the direction of transfer or its magnitude, while mass diffusivity most commonly requires information about bulk motion of the medium in which diffusion occurs. For liquids, it is common to refer to the limit of infinite dilution of A in B using the symbol, D°_{AB}.

When the flux expressions are consistent, as in Eq. (5-190), the diffusivities in Eq. (5-189) are identical. As a result, experimental diffusivities are often measured under constant volume conditions but may be used for applications involving open systems. It turns out that the two versions are very nearly equivalent for gas-phase systems because there is negligible volume change on mixing. That is not usually true for liquids, however.

Self-Diffusivity **Self-diffusivity** is denoted by $D_{A'A}$ and is the measure of mobility of a species in itself; for instance, using a small concentration of molecules tagged with a radioactive isotope so they can be detected. Tagged and untagged molecules presumably do not have significantly different properties. Hence, the solution is ideal, and there are practically no gradients to "force" or "drive" diffusion. This kind of diffusion is presumed to be purely statistical in nature.

In the special case that A and B are similar in molecular weight, polarity, and so on, the self-diffusion coefficients of pure A and B will be approximately equal to the mutual diffusivity, D_{AB}. Second, when A and B are the less mobile and more mobile components, respectively, their self-diffusion coefficients can be used as rough lower and upper bounds of the mutual diffusion coefficient. That is, $D_{A'A} \le D_{AB} \le D_{B'B}$. Third, it is a common means for evaluating diffusion for gases at high pressure. Self-diffusion in liquids has been studied by many [Easteal, *AIChE J.* **30,** 641 (1984), Ertl and Dullien, *AIChE J.* **19,** 1215 (1973), and Vadovic and Colver, *AIChE J.* **18,** 1264 (1972)].

Tracer Diffusivity **Tracer diffusivity,** denoted by $D_{A'B}$ is related to both mutual and self-diffusivity. It is evaluated in the presence of a second component B, again using a tagged isotope of the first component. In the dilute range, tagging A merely provides a convenient method for indirect composition analysis. As concentration varies, tracer diffusivities approach mutual diffusivities at the dilute limit, and they approach self-diffusivities at the pure component limit. That is, at the limit of dilute A in B, $D_{A'B} \rightarrow D^{\circ}_{AB}$ and $D_{B'A} \rightarrow D_{B'B}$; likewise at the limit of dilute B in A, $D_{B'A} \rightarrow D^{\circ}_{BA}$ and $D_{A'B} \rightarrow D_{A'A}$.

Neither the tracer diffusivity nor the self-diffusivity has much practical value except as a means to understand ordinary diffusion and as order-of-magnitude estimates of mutual diffusivities. Darken's equation [Eq. (5-230)] was derived for tracer diffusivities but is often used to relate mutual diffusivities at moderate concentrations as opposed to infinite dilution.

Mass-Transfer Coefficient Denoted by k_c, k_x, K_x, and so on, the mass-transfer coefficient is the ratio of the flux to a concentration (or composition) difference. These coefficients generally represent rates of transfer that are much greater than those that occur by diffusion alone, as a result of convection or turbulence at the interface where mass transfer occurs. There exist several principles that relate that coefficient to the diffusivity and other fluid properties and to the intensity of motion and geometry. Examples that are outlined later are the film theory, the surface renewal theory, and the penetration theory, all of which pertain to idealized cases. For many situations of practical interest like investigating the flow inside tubes and over flat surfaces as well as measuring external flow through banks of tubes, in fixed beds of particles, and the like, correlations have been developed that follow the same forms as the above theories. Examples of these are provided in the subsequent section on mass-transfer coefficient correlations.

Problem Solving Methods Most, if not all, problems or applications that involve mass transfer can be approached by a systematic course of action. In the simplest cases, the unknown quantities are obvious. In more complex (e.g., multicomponent, multiphase, multidimensional, nonisothermal, and/or transient) systems, it is more subtle to resolve the known and unknown quantities. For example, in multicomponent systems, one must know the fluxes of the components before predicting their effective diffusivities and vice versa. More will be said about that dilemma later. Once the known and unknown quantities are resolved, however, a combination of conservation equations, definitions, empirical relations, and properties are

Nomenclature and Units—Mass Transfer

Symbols	Definition	SI units	U.S. Customary units
a	Effective interfacial mass transfer area per unit volume	m^2/m^3	ft^2/ft^3
A_{cs}	Cross-sectional area of vessel	m^2 or cm^2	ft^2
A'	Constant (see Table 5-24-K)		
a_p	See a		
c	Concentration = P/RT for an ideal gas	mol/m^3 or mol/l or gequiv/l	$lbmol/ft^3$
c_i	Concentration of component $i = x_i c$ at gas-liquid interface	mol/m^3 or mol/l or gequiv/l	$lbmol/ft^3$
c_P	Specific heat	kJ/(kg·K)	Btu/(lb·°F)
d	Characteristic length	m or cm	ft
d_b	Bubble diameter	m	ft
d_c	Column diameter	m or cm	ft
d_{drop}	Sauter mean diameter	m	ft
d_{imp}	Impeller diameter	m	ft
d_{pore}	Pore diameter	m or cm	ft
$D_{A'A}$	Self-diffusivity (= D_A at $x_A = 1$)	m^2/s or cm^2/s	ft^2/h
D_{AB}	Mutual diffusivity	m^2/s or cm^2/s	ft^2/h
D°_{AB}	Mutual diffusivity at infinite dilution of A in B	m^2/s or cm^2/s	ft^2/h
D_{eff}	Effective diffusivity within a porous solid = $\varepsilon_p D/\tau$	m^2/s	ft^2/h
D_K	Knudson diffusivity for gases in small pores	m^2/s or cm^2/s	ft^2/h
D_L	Liquid phase diffusion coefficient	m^2/s	ft^2/h
D_S	Surface diffusivity	m^2/s or cm^2/s	ft^2/h
E	Energy dissipation rate/mass		
E_S	Activation energy for surface diffusion	J/mol or cal/mol	
f	Friction factor for fluid flow	Dimensionless	Dimensionless
F	Faraday's constant	96,487 Coulomb/gequiv	
g	Acceleration due to gravity	m/s^2	ft/h^2
g_c	Conversion factor	1.0	4.17×10^8 lb ft/[lbf·h^2]
G	Gas-phase mass flux	kg/(s·m^2)	lb/(h·ft^2)
G_a	Dry air flux	kg/(s·m^2)	lb/(h·ft^2)
G_M	Molar gas-phase mass flux	kmol/(s·m^2)	(lbmol)/(h·ft^2)
h'	Heat transfer coefficient	W/(m^2·K) = J/(s·m^2·K)	Btu/(h·ft^2·°F)
h_T	Total height of tower packing	m	ft
H	Compartment height	m	ft
H	Henry's law constant	kPa/(mole-fraction solute in liquid phase)	(lbf/in^2)/(mole-fraction solute in liquid phase)
H'	Henry's law constant	kPa/[kmol/(m^3 solute in liquid phase)]	(lbf/in^2)/[(lbmol)/(ft^3 solute in liquid phase)] or atm/[(lbmole)/(ft^3 solute in liquid phase)]
H_G	Height of one transfer unit based on gas-phase resistance	m	ft
H_{OG}	Height of one overall gas-phase mass-transfer unit	m	ft
H_L	Height of one transfer unit based on liquid-phase resistance	m	ft
H_{OL}	Height of one overall liquid-phase mass-transfer unit	m	ft
HTU	Height of one transfer unit (general)	m	ft
j_D	Chilton-Colburn factor for mass transfer, Eq. (5-289)	Dimensionless	Dimensionless
j_H	Chilton-Colburn factor for heat transfer	Dimensionless	Dimensionless
j_M	See j_D		
$_mJ_A$	Mass flux of A by diffusion with respect to the mean mass velocity	kmol/(m^2·s) or mol/(cm^2·s)	lbmol/(ft^2·h)
$_MJ_A$	Molar flux of A by diffusion with respect to mean molar velocity	kmol/(m^2·s) or mol/(cm^2·s)	lbmol/(ft^2·h)
$_VJ_A$	Molar flux of A with respect to mean volume velocity	kmol/(m^2·s)	lbmol/(ft^2·h)
J_{Si}	Molar flux by surface diffusion	kmol/(m^2·s) or gmol/(cm^2·s)	lbmol/(ft^2·h)
k	Boltzmann's constant	8.9308×10^{-10} gequiv ohm/s	
k	Film mass transfer coefficient	m/s or cm/s	ft/hr
k	Thermal conductivity	(J·m)/(s·m^2·K)	Btu/(h·ft·°F)
k'	Mass-transfer coefficient for dilute systems	kmol/[(s·m^2)(kmol/m^3)] or m/s	lbmol/[(h·ft^2)(lbmol/ft^3)] or ft/hr
k_G	Gas-phase mass-transfer coefficient for dilute systems	kmol/[(s·m^2)(kPa solute partial pressure)]	lbmol/[(h·ft^2)lbf/in^2 solute partial pressure)]
k'_G	Gas-phase mass-transfer coefficient for dilute systems	kmol/[(s·m^2)(mole fraction in gas)]	lbmol/[(h·ft^2)(mole fraction in gas)]
$k_G a$	Volumetric gas-phase mass-transfer	kmol/[(s·m^3)(mole fraction)]	(lbmol)/[(h·ft^3)(mole fraction)]
$\hat{k}_G a$	Overall volumetric gas-phase mass-transfer coefficient for concentrated systems	kmol/(s·m^3)	lbmol/(h·ft^3)
$\hat{k}^\circ_L$	Liquid phase mass transfer coefficient for pure absorption (no reaction)	kmol/(s·m^2)	lbmol/(h·ft^2)
k_L	Liquid-phase mass-transfer coefficient for dilute systems	kmol/[(s·m^2)(mole-fraction solution in liquid)]	(lbmol)/[(h·ft^2)(mole-fraction solute in liquid)]
k'_L	Liquid-phase mass-transfer coefficient for dilute systems	kmol/[(s·m^2)(kmol/m^3)] or m/s	(lbmol)/[(h·ft^2)(lbmol/ft^3)] or ft/h
$\hat{k}_L$	Liquid-phase mass-transfer coefficient for concentrated systems	kmol/(s·m^2)	lbmol/(h·ft^2)
$k_L a$	Volumetric liquid-phase mass-transfer coefficient for dilute systems	kmol/[(s·m^3)(mole fraction)]	(lbmol)/[(h·ft^3)(mole fraction)]
K	Overall mass transfer coefficient	m/s or cm/s	ft/h
K	α/R = specific conductance	ohm/cm	
K_G	Overall gas-phase mass-transfer coefficient for dilute systems	kmol/[(s·m^2)(mole fraction)]	(lbmol)/[(h·ft^2)(mole fraction)]

Nomenclature and Units—Mass Transfer (*Continued*)

Symbols	Definition	SI units	U.S. Customary units
$\hat{K}_G$	Overall gas-phase mass-transfer coefficient for concentrated systems	kmol/(s·m^2)	lbmol/(h·ft^2)
$K_G a$	Overall volumetric gas-phase mass-transfer dilute systems	kmol/[(s·m^3)(mole-fraction solute in gas)]	(lbmol)/[(h·ft^3(mole-fraction solute in gas)]
$K'_G a$	Overall volumetric gas-phase mass-transfer dilute systems	kmol/[(s·m^3)(kPa solute partial pressure)]	(lbmol)/[(h·ft^3)(lbf/in^2 solute partial pressure)]
$(Ka)_H$	Overall enthalpy mass-transfer coefficient	kmol/[(s·m^2)(mole fraction)]	lb/[(h·ft^3)(lb water/lb dry air)]
K_L	Overall liquid-phase mass-transfer coefficient	kmol/[(s·m^2)(mole fraction)]	(lbmol)/[(h·ft^2)(mole fraction)]
$\hat{K}_L$	Liquid-phase mass-transfer coefficient for concentrated systems	kmol/(s·m^2)	(lbmol)/(h·ft^2)
$K_L a$	Overall volumetric liquid-phase mass-transfer coefficient for dilute systems	kmol/[(s·m^3)(mole-fraction solute in liquid)]	(lbmol)/[(h·ft^3)(mole-fraction solute in liquid)]
$\hat{K}_L a$	Overall volumetric liquid-phase mass-transfer coefficient for concentrated systems	kmol/(s·m^3)	(lbmol)/(h·ft^3)
L	Liquid-phase mass flux	kg/(s·m^2)	lb/(h·ft^2)
L_M	Molar liquid-phase mass flux	kmol/(s·m^2)	(lbmol)/(h·ft^2)
m	Slope of equilibrium curve = dy/dx (mole-fraction solute in gas)/(mole-fraction solute in liquid)	Dimensionless	Dimensionless
m	Molality of solute	mol/1000 g solvent	
M_i	Molecular weight of species i	kg/kmol or g/mol	lb/lbmol
M	Mass in a control volume V	kg or g	lb
$\lvert n_+ \rvert \lvert n_- \rvert$	Valences of cationic and anionic species	Dimensionless	Dimensionless
n'	See Table 5-24-K	Dimensionless	Dimensionless
n_A	Mass flux of A with respect to fixed coordinates	kg/(s·m^2)	lb/(h·ft^2)
N	Impeller speed	Revolution/s	Revolution/min
N'	Number deck levels	Dimensionless	Dimensionless
N_A	Interphase mass-transfer rate of solute A per interfacial area with respect to fixed coordinates	kmol/(s·m^2)	(lbmol)/(h·ft^2)
N_c	Number of components	Dimensionless	Dimensionless
N_{Fr}	Froude Number ($d_{imp} N^2$/g)	Dimensionless	Dimensionless
N_{Gr}	Grashof number $\left(\frac{gx^3}{(\mu/\rho)^2}\left(\frac{\rho_\infty}{\rho_o}-1\right)\right)$	Dimensionless	Dimensionless
N_{OG}	Number of overall gas-phase mass-transfer units	Dimensionless	Dimensionless
N_{OL}	Number of overall liquid-phase mass-transfer units	Dimensionless	Dimensionless
NTU	Number of transfer units (general)	Dimensionless	Dimensionless
N_{Kn}	Knudson number = l/d_{pore}	Dimensionless	Dimensionless
N_{Pr}	Prandtl number ($c_p\mu/k$)	Dimensionless	Dimensionless
N_{Re}	Reynolds number (Gd/μ_G)	Dimensionless	Dimensionless
N_{Sc}	Schmidt number ($\mu_G/\rho_G D_{AB}$) or ($\mu_L/\rho_L D_L$)	Dimensionless	Dimensionless
N_{Sh}	Sherwood number ($\hat{k}_G RTd/D_{AB} p_T$), see also Tables 5-17 to 5-24	Dimensionless	Dimensionless
N_{St}	Stanton number ($\hat{k}_G/G_M$) or ($\hat{k}_L/L_M$)	Dimensionless	Dimensionless
N_W	Weber number ($\rho_c N^2 d^3_{imp}/\sigma$)	Dimensionless	Dimensionless
p	Solute partial pressure in bulk gas	kPa	lbf/in^2
$p_{B,M}$	Log mean partial pressure difference of stagnant gas B	Dimensionless	Dimensionless
p_i	Solute partial pressure at gas-liquid interface	kPa	lbf/in^2
p_T	Total system pressure	kPa	lbf/in^2
P	Pressure	Pa	lbf/in^2 or atm
P	Power	Watts	
P_c	Critical pressure	Pa	lbf/in^2 or atm
Per	Perimeter/area	m^{-1}	ft^{-1}
Q	Volumetric flow rate	m^3/s	ft^3/h
r_A	Radius of dilute spherical solute	Å	
R	Gas constant	8.314 J/mol K = 8.314 Pa m^3/(mol K) = 82.057 atm cm^3/mol K	10.73 ft^3 psia/lbmol·h
$\boldsymbol{R}$	Solution electrical resistance	ohm	
R_i	Radius of gyration of the component i molecule	Å	
s	Fractional surface-renewal rate	s^{-1}	h^{-1}
S	Tower cross-sectional area = $\pi d^2/4$	m^2	ft^2
t	Contact time	s	h
t_f	Formation time of drop	s	h
T	Temperature	K	°R
T_b	Normal boiling point	K	°R
T_c	Critical temperature	K	°R
T_r	Reduced temperature = T/T_c	Dimensionless	Dimensionless
u, v	Fluid velocity	m/s or cm/s	ft/h
u_o	Blowing or suction velocity	m/s	ft/h
u_∞	Velocity away from object	m/s	ft/h
u_L	Superficial liquid velocity in vertical direction	m/s	ft/h
v_s	Slip velocity	m/s	ft/h
v_T	Terminal velocity	m/s	ft/h
v_{TS}	Stokes law terminal velocity	m/s	ft/h
V	Packed volume in tower	m^3	ft^3
V	Control volume	m^3 or cm^3	ft^3
V_b	Volume at normal boiling point	m^3/kmol or cm^3/mol	ft^3/lbmol
V_i	Molar volume of i at its normal boiling point	m^3/kmol or cm^3/mol	ft^3/lbmol
$\bar{v}_i$	Partial molar volume of i	m^3/kmol or cm^3/mol	ft^3/lbmol

Nomenclature and Units—Mass Transfer (*Concluded*)

Symbols	Definition	SI units	U.S. Customary units
V_{mli}	Molar volume of the liquid-phase component i at the melting point	m^3/kmol or cm^3/mol	ft^3/lbmol
V_{tower}	Tower volume per area	m^3/m^2	ft^3/ft^2
w	Width of film	m	ft
x	Length along plate	m	ft
x	Mole-fraction solute in bulk-liquid phase	(kmol solute)/(kmol liquid)	(lbmol solute)/(lb mol liquid)
x_A	Mole fraction of component A	kmole A/kmole fluid	lbmol A/lb mol fluid
x^o	Mole-fraction solute in bulk liquid in equilibrium with bulk-gas solute concentration y	(kmol solute)/(kmol liquid)	(lbmol solute)/(lbmol liquid)
x_{BM}	Logarithmic-mean solvent concentration between bulk liquid and interface values	(kmol solvent)/(kmol liquid)	(lbmol solvent)/(lbmol liquid)
x^o_{BM}	Logarithmic-mean inert-solvent concentration between bulk-liquid value and value in equilibrium with bulk gas	(kmol solvent)/(kmol liquid)	(lbmol solvent)/(lbmol liquid)
x_i	Mole-fraction solute in liquid at gas-liquid interface	(kmol solute)/(kmol liquid)	(lbmol solute)/(lbmol liquid)
y	Mole-fraction solute in bulk-gas phase	(kmol solute)/(kmol gas)	(lbmol solute)/(lbmol gas)
y_{BM}	Logarithmic-mean inert-gas concentration [Eq. (5-275)]	(kmol inert gas)/(kmol gas)	(lbmol inert gas)/(lbmol gas)
y^o_{BM}	Logarithmic-mean inert-gas concentration	(kmol inert gas)/(kmol gas)	(lbmol inert gas)/(lbmol gas)
y_i	Mole fraction solute in gas at interface	(kmole solute)/(kmol gas)	(lbmol solute)/(lbmol gas)
y_i^o	Mole-fraction solute in gas at interface in equilibrium with the liquid-phase interfacial solute concentration x_i	(kmol solute)/(kmol gas)	(lbmol solute)/(lbmol gas)
z	Direction of unidimensional diffusion	m	ft
	Greek Symbols		
α	$1 + N_B/N_A$	Dimensionless	Dimensionless
α	Conductance cell constant (measured)	cm^{-1}	
β	$M_A^{1/2} P_c^{1/3}/T_c^{5/6}$	Dimensionless	Dimensionless
δ	Effective thickness of stagnant-film layer	m	ft
ε	Fraction of discontinuous phase in continuous phase for two-phase flow	Dimensionless	Dimensionless
ε	Void fraction available for gas flow or fractional gas holdup	m^3/m^3	ft^3/ft^3
ε_A	Characteristic Lennard-Jones energy	Dimensionless	Dimensionless
ε_{AB}	$(\varepsilon_A\varepsilon_B)^{1/2}$	Dimensionless	Dimensionless
γ_i	Activity coefficient of solute i	Dimensionless	Dimensionless
$\gamma_\pm$	Mean ionic activity coefficient of solute	Dimensionless	Dimensionless
$\lambda_+ \ \lambda_-$	Infinite dilution conductance of cation and anion	cm^2/(gequiv·ohm)	
Λ	$1000\ K/C = \lambda_+ + \lambda_- = \Lambda_o + f(C)$	cm^2/ohm gequiv	
Λ_o	Infinite dilution conductance	cm^2/gequiv ohm	
μ_i	Dipole moment of i	Debeyes	
μ_i	Viscosity of pure i	cP or Pa s	lb/(h·ft)
μ_G	Gas-phase viscosity	kg/(s·m)	lb/(h·ft)
μ_L	Liquid-phase viscosity	kg/(s·m)	lb/(h·ft)
ν	Kinematic viscosity = ρ/μ	m^2/s	ft^2/h
ρ	Density of A	kg/m^3 or g/cm^3	lb/ft^3
ρ_c	Critical density of A	kg/m^3 or g/cm^3	lb/ft^3
ρ_c	Density continuous phase	kg/m^3	lb/ft^3
ρ_G	Gas-phase density	kg/m^3	lb/ft^3
$\bar{\rho}_L$	Average molar density of liquid phase	$kmol/m^3$	$(lbmol)/ft^3$
ρ_p	Particle density	kg/m^3 or g/cm^3	lb/ft^3
ρ_r	Reduced density = ρ/ρ_c	Dimensionless	Dimensionless
ψ_i	Parachor of component $i = V_i\sigma^{1/4}$		
ψ	Parameter, Table 5-24-G	Dimensionless	Dimensionless
σ	Interfacial tension	dyn/cm	lbf/ft
σ_i	Characteristic length	Å	
σ_i	Surface tension of component i	dyn/cm	
σ_{AB}	Binary pair characteristic length = $(\sigma_A + \sigma_B)/2$	Å	
τ	Intraparticle tortuosity	Dimensionless	Dimensionless
ω	Pitzer's acentric factor = $-[1.0 + \log 10(P^*/P_c)]$	Dimensionless	
ω	Rotational velocity	Radians/s	
Ω	Diffusion collision integral = $f(kT/\varepsilon_{AB})$	Dimensionless	Dimensionless
	Subscripts		
A	Solute component in liquid or gas phase		
B	Inert-gas or inert-solvent component		
G	Gas phase		
m	Mean value		
L	Liquid phase		
super	Superficial velocity		
	Superscript		
°	At equilibrium		

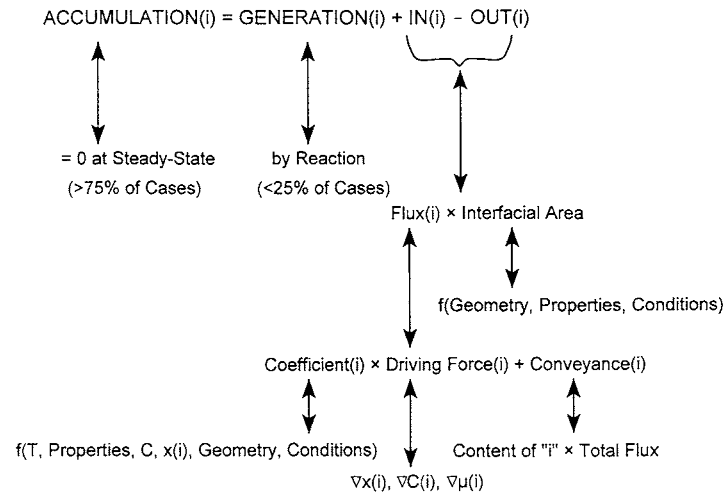

FIG. 5-24 Flowchart illustrating problem solving approach using mass-transfer rate expressions in the context of mass conservation.

applied to arrive at an answer. Figure 5-24 is a flowchart that illustrates the primary types of information and their relationships, and it applies to many mass-transfer problems.

CONTINUITY AND FLUX EXPRESSIONS

Material Balances Whenever mass-transfer applications involve equipment of specific dimensions, flux equations alone are inadequate to assess results. A material balance or continuity equation must also be used. When the geometry is simple, macroscopic balances suffice. The following equation is an overall mass balance for such a unit having N_m bulk-flow ports and N_n ports or interfaces through which diffusive flux can occur:

$$\frac{dM}{dt} = \sum_{i=1}^{N_m} m_i + \sum_{i=1}^{N_n} n_i A_{cs_i} \tag{5-191}$$

where M represents the mass in the unit volume V at any time t; m_i is the mass flow rate through the ith port; and n_i is the mass flux through the ith port, which has a cross-sectional area of A_{cs_i}. The corresponding balance equation for individual components includes a reaction term:

$$\frac{dM_j}{dt} = \sum_{i=1}^{N_m} m_{ij} + \sum_{i=1}^{N_n} n_{ij} A_{cs_i} + r_j V \tag{5-192}$$

For the jth component, $m_{ij} = m_i w_{ij}$ is the component mass flow rate in stream i; w_{ij} is the mass fraction of component j in stream i; and r_j is the net reaction rate (mass generation minus consumption) per unit volume V that contains mass M. If it is inconvenient to measure mass flow rates, the product of density and volumetric flow rate is used instead.

In addition, most situations that involve mass transfer require material balances, but the pertinent area is ambiguous. Examples are packed columns for absorption, distillation, or extraction. In such cases, flow rates through the discrete ports (nozzles) must be related to the mass-transfer rate in the packing. As a result, the mass-transfer rate is determined via flux equations, and the overall material balance incorporates the stream flow rates m_i and integrated fluxes. In such instances, it is common to begin with the most general, differential material balance equations. Then, by eliminating terms that are negligible, the simplest applicable set of equations remains to be solved. Table 5-8 provides material balances for Cartesian, cylindrical, and spherical coordinates. The generic form applies over a unit cross-sectional area and constant volume:

$$\frac{\partial \rho_j}{\partial t} = -\nabla \cdot n_j + r_j \tag{5-193a}$$

where $n_j = \rho v_j$. Applying Fick's law and expressing composition as concentration gives

$$\frac{\partial c_j}{\partial t} = -v \cdot \nabla c_j + D_j \nabla^2 c_j + r_j \tag{5-193b}$$

Flux Expressions: Simple Integrated Forms of Fick's First Law Simplified flux equations that arise from Eqs. (5-189) and (5-190) can be used for unidimensional, steady-state problems with binary mixtures. The boundary conditions represent the compositions x_{A_L} and x_{A_R} at the left-hand and right-hand sides of a hypothetical layer having thickness Δz. The principal restriction of the following equations is that the concentration and diffusivity are assumed to be constant. As written, the flux is positive from left to right, as depicted in Fig. 5-25.

1. Equimolar counterdiffusion ($N_A = -N_B$)

$$N_A = {}_MJ_A = -D_{AB}\, c\, \frac{dx_A}{dz} = \frac{D_{AB}}{\Delta z}\, c\, (x_{A_L} - x_{A_R}) \tag{5-197}$$

TABLE 5-8 Continuity Equation in Various Coordinate Systems

Coordinate System	Equation
Cartesian	$\frac{\partial \rho_j}{\partial t} = -\left(\frac{\partial n_{x_j}}{\partial x} + \frac{\partial n_{y_j}}{\partial y} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ (5-194)
Cylindrical	$\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r}\frac{\partial r n_{r_j}}{\partial r} + \frac{1}{r}\frac{\partial n_{\theta_j}}{\partial \theta} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ (5-195)
Spherical	$\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r^2}\frac{\partial r^2 n_{r_j}}{\partial r} + \frac{1}{r \sin\theta}\frac{\partial n_{\theta_j} \sin\theta}{\partial \theta} + \frac{1}{r \sin\theta}\frac{\partial n_{\phi_j}}{\partial \phi}\right) + r_j$ (5-196)

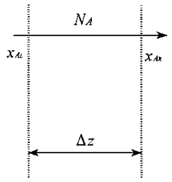

FIG. 5-25 Hypothetical film and boundary conditions.

2. Unimolar diffusion ($N_A \neq 0, N_B = 0$)

$$N_A = {}_MJ_A + x_AN_A = \frac{D_{AB}}{\Delta z} c \ln \frac{1 - x_{A_R}}{1 - x_{A_L}} \tag{5-198}$$

3. Steady state diffusion ($N_A \neq -N_B \neq 0$)

$$N_A = {}_MJ_A + x_A(N_A + N_B) = \frac{N_A}{N_A + N_B} \frac{D_{AB}}{\Delta z} c \ln \frac{\dfrac{N_A}{N_A + N_B} - x_{A_R}}{\dfrac{N_A}{N_A + N_B} - x_{A_L}} \tag{5-199}$$

The unfortunate aspect of the last relationship is that one must know a priori the ratio of the fluxes to determine the magnitudes. It is not possible to solve simultaneously the pair of equations that apply for components A and B because the equations are not independent.

Stefan-Maxwell Equations Following Eq. (5-190), a simple and intuitively appealing flux equation for applications involving N_c components is

$$N_i = -cD_{im} \nabla x_i + x_i \sum_{j=1}^{N_c} N_j \tag{5-200}$$

In the late 1800s, the development of the kinetic theory of gases led to a method for calculating multicomponent gas diffusion (e.g., the flux of each species in a mixture). The methods were developed simultaneously by Stefan and Maxwell. The problem is to determine the diffusion coefficient D_{im}. The Stefan-Maxwell equations are simpler in principle since they employ binary diffusivities:

$$\nabla x_i = \sum_{j=1}^{N_c} \frac{1}{cD_{ij}} (x_iN_j - x_jN_i) \tag{5-201}$$

If Eqs. (5-200) and (5-201) are combined, the multicomponent diffusion coefficient may be assessed in terms of binary diffusion coefficients [see Eq. (5-214)]. For gases, the values D_{ij} of this equation are approximately equal to the binary diffusivities for the ij pairs. The Stefan-Maxwell diffusion coefficients may be negative, and the method may be applied to liquids, even for electrolyte diffusion [Kraaijeveld, Wesselingh, and Kuiken, *Ind. Eng. Chem. Res.*, **33,** 750 (1994)]. Approximate solutions have been developed by linearization [Toor, H.L., *AIChE J.*, **10,** 448 and 460 (1964); Stewart and Prober, *Ind. Eng. Chem. Fundam.*, **3,** 224 (1964)]. Those differ in details but yield about the same accuracy. More recently, efficient algorithms for solving the equations exactly have been developed (see Taylor and Krishna, Krishnamurthy and Taylor [*Chem. Eng. J.*, **25,** 47 (1982)], and Taylor and Webb [*Comput. Chem. Eng.*, **5,** 61 (1981)].

Useful studies of multicomponent diffusion were presented by Vrentas and Vrentas [*Ind. Eng. Chem. Res.* **44,** 1112 (2005)], Curtis and Bird [*Ind. Eng. Chem. Res.* **38,** 2515 (1999)], and Amundson, Pan, and Paulson [*AIChE J.* **48,** 813 (2003)]. Vrentas and Vrentas treated only ternary mixtures, such as restrictions due to the entropy inequality, application of the Onsager reciprocal relations, and stability. Curtis and Bird reconciled the multicomponent Fick's law approach with the more elegant Stefan-Maxwell theory. They also provided interrelationships of multicomponent diffusivities devised for various situations, i.e., binary, ternary, and quaternary mixtures. Amundson et al. presented numerical methods for coping with mixtures having four or more components, which are nearly intractable via the analytical S-M method, due to the difficult inversion. Related studies were performed by Ghorayeb and Firoozabadi [*AIChE J.* **46,** 883 (2000)] and Firoozabadi, Ghorayeb, and Saukla [*AIChE J.* **46,** 892 (2000)]. The former covered ordinary molecular diffusion as well as pressure and thermal diffusion for multicomponent mixtures. The latter covered thermal diffusion in multicomponent mixtures.

DIFFUSIVITY ESTIMATION—GASES

Whenever measured values of diffusivities are available, they should be used. Typically, measurement errors are less than those associated with predictions by empirical or even semitheoretical equations. A few general sources of data are Sec. 2 of this handbook; e.g., experimental values for gas mixtures are listed in Table 2-371. Estimation methods for some gaseous applications appear in Eqs. (2-150) through (2-154). Other pertinent references are Schwartzberg and Chao; Poling et al.; Gammon et al.; and Daubert and Danner. Many other more restricted sources are listed under specific topics later in this subsection.

Before using diffusivities from either data or correlations, it is a good idea to check their reasonableness with respect to values that have been commonly observed in similar situations. Table 5-9 is a compilation of several rules of thumb. These values are not authoritative; they simply represent guidelines based on experience.

Diffusivity correlations for gases are outlined in Table 5-10. Specific parameters for individual equations are defined in the specific text regarding each equation. References are given at the beginning of the "Mass Transfer" subsection. The errors reported for Eqs. (5-202) through (5-205) were compiled by Poling et al., who compared the predictions with 68 experimental values of D_{AB}. Errors cited for Eqs. (5-206) to (5-212) were reported by the authors.

Binary Mixtures—Low Pressure—Nonpolar Components Many evaluations of correlations are available [Elliott and Watts, *Can. J. Chem.*, **50,** 31 (1972); Lugg, *Anal. Chem.*, **40,** 1072 (1968); Marrero and Mason, *AIChE J.*, **19,** 498 (1973)]. The differences in accuracy of the correlations are minor, and thus the major concern is ease of calculation. The Fuller-Schettler-Giddings equation is usually the simplest correlation to use and is recommended by Poling et al.

Chapman-Enskog (Bird et al.) and Wilke and Lee [31] The inherent assumptions of these equations are quite restrictive (i.e., low density, spherical atoms), and the intrinsic potential function is empirical. Despite that, they provide good estimates of D_{AB} for many polyatomic gases and gas mixtures, up to about 1000 K and a maximum of 70 atm. The latter constraint is because observations for many gases indicate that $D_{AB}P$ is constant up to 70 atm.

The characteristic length is $\sigma_{AB} = (\sigma_A + \sigma_B)/2$ in Å. In order to estimate Ω_D for Eq. (5-202) or (5-203), two empirical equations are

TABLE 5-9 Rules of Thumb for Diffusivities (See Cussler, Poling et al., Schwartzberg and Chao)

	D_i magnitude		D_i range		
Continuous phase	m²/s	cm²/s	m²/s	cm²/s	Comments
Gas at atmospheric pressure	10^{-5}	0.1	10^{-4}–10^{-6}	1–10^{-2}	Accurate theories exist, generally within ±10%; $D_iP \cong$ constant; $D_i \propto T^{1.66 \text{ to } 2.0}$
Liquid	10^{-9}	10^{-5}	10^{-8}–10^{-10}	10^{-4}–10^{-6}	Approximate correlations exist, generally within ±25%
Liquid occluded in solid matrix	10^{-10}	10^{-6}	10^{-8}–10^{-12}	10^{-4}–10^{-8}	Hard cell walls: D_{eff}/D_i = 0.1 to 0.2. Soft cell walls: D_{eff}/D_i = 0.3 to 0.9
Polymers and glasses	10^{-12}	10^{-8}	10^{-10}–10^{-14}	10^{-6}–10^{-10}	Approximate theories exist for dilute and concentrated limits; strong composition dependence
Solid	10^{-14}	10^{-10}	10^{-10}–10^{-34}	10^{-6}–10^{-30}	Approximate theories exist; strong temperature dependence

TABLE 5-10 Correlations of Diffusivities for Gases

Authors*	Equation		Error, %
	1. Binary Mixtures—Low Pressure—Nonpolar		
Chapman-Enskog	$D_{AB} = \dfrac{0.001858 T^{3/2} M_{AB}^{1/2}}{P \sigma_{AB}^2 \Omega_D}$	(5-202)	7.3
Wilke-Lee [31]	$D_{AB} = \dfrac{(0.00217 - 0.0005 M_{AB}^{1/2})\, T^{3/2} M_{AB}^{1/2}}{P \sigma_{AB}^2 \Omega_D}$	(5-203)	7.0
Fuller-Schettler-Giddings [10]	$D_{AB} = \dfrac{0.001 T^{1.75} M_{AB}^{1/2}}{P\, [(\sum v)_A^{1/3} + (\sum v)_B^{1/3}]^2}$	(5-204)	5.4
	2. Binary Mixtures—Low Pressure—Polar		
Brokaw [4]	$D_{AB} = \dfrac{0.001858 T^{3/2} M_{AB}^{1/2}}{P \sigma_{AB}^2 \Omega_D}$	(5-205)	9.0
	3. Self-Diffusivity		
Mathur-Thodos [18]	$D_{AA} = \dfrac{10.7 \times 10^{-5} T_r}{\beta \rho_r} \; \{\rho_r \le 1.5\}$	(5-206)	5
Lee-Thodos [14]	$D_{AA} = \dfrac{0.77 \times 10^{-5} T_r}{\rho_r \delta} \; \{\rho_r \le 1\}$	(5-207)	0.5
Lee-Thodos [15]	$D_{AA} = \dfrac{(0.007094 G + 0.001916)^{2.5} T_r}{\delta}, \; [\rho_r > 1, G < 1]$	(5-208)	17
	4. Supercritical Mixtures		
Sun and Chen [25]	$D_{AB} = \dfrac{1.23 \times 10^{-10} T}{\mu^{0.799} V_{C_A}^{0.49}}$	(5-209)	5
Catchpole and King [6]	$D_{AB} = 5.152\, D_c T_r \dfrac{(\rho^{-0.667} - 0.4510)\,(1 + M_A/M_B)\, R}{(1 + (V_{c_B}/V_{c_A})^{0.333})^2}$	(5-210)	10
Liu and Ruckenstein [17]	$D_{AB} = \dfrac{kT}{f \pi \mu_A \sigma_{AB}} \left[\dfrac{1}{1 + \dfrac{2}{3}\left(1 - \dfrac{1}{2}\theta_{AB}^{\infty}\right)^{1/2}} + \dfrac{\sigma_{AB}}{3\sigma_A} \right]$	(5-211)	5.7
	$D_{AB} = \alpha\left(V_A^k - \beta\right)\sqrt{\dfrac{T}{M_B}}, \quad \alpha = 10^{-5}\left[0.56392 + 2.1417 \exp\left(\dfrac{-0.95088 \sqrt{M_A V_{C_A}}}{P_{C_A}}\right)\right]$	(5-212)	6.9
	$\beta = 8.9061 + 0.93858 \dfrac{\sqrt{M_A V_{C_A}}}{P_{C_A}}$		
	$k = \dfrac{2}{3}[1 - 0.28 \exp(-0.3 \sqrt{M_A}\, \rho_{\iota_A})]$		

*References are listed at the beginning of the "Mass Transfer" subsection.

available. The first is:

$$\Omega_D = (44.54 T^{*-4.909} + 1.911 T^{*-1.575})^{0.10} \tag{5-213a}$$

where $T^* = kT/\varepsilon_{AB}$ and $\varepsilon_{AB} = (\varepsilon_A\, \varepsilon_B)^{1/2}$. Estimates for σ_i and ε_i are given in Table 5-11. This expression shows that Ω_D is proportional to temperature roughly to the –0.49 power at low temperatures and to the –0.16 power at high temperature. Thus, gas diffusivities are proportional to temperatures to the 2.0 power and 1.66 power, respectively, at low and high temperatures. The second is:

$$\Omega_D = \frac{A}{T^{*B}} + \frac{C}{\exp(DT^*)} + \frac{E}{\exp(FT^*)} + \frac{G}{\exp(HT^*)} \tag{5-213b}$$

TABLE 5-11 Estimates for ε_i and σ_i (K, Å, atm, cm³, mol)

Critical point	$\varepsilon/k = 0.75\, T_c$	$\sigma = 0.841\, V_c^{1/3}$ or $2.44\, (T_c/P_c)^{1/3}$
Critical point	$\varepsilon/k = 65.3\, T_c z_c^{3.6}$	$\sigma = \dfrac{1.866\, V_c^{1/3}}{z_c^{1.2}}$
Normal boiling point	$\varepsilon/k = 1.15\, T_b$	$\sigma = 1.18\, V_b^{1/3}$
Melting point	$\varepsilon/k = 1.92\, T_m$	$\sigma = 1.222\, V_m^{1/3}$
Acentric factor	$\varepsilon/k = (0.7915 + 0.1693\, \omega)\, T_c$	$\sigma = (2.3551 - 0.087\, \omega)\left(\dfrac{T_c}{P_c}\right)^{1/3}$

NOTE: These values may not agree closely, so usage of a consistent basis is suggested (e.g., data at the normal boiling point).

TABLE 5-12 Atomic Diffusion Volumes for Use in Estimating D_{AB} by the Method of Fuller, Schettler, and Giddings [10]

Atomic and Structural Diffusion–Volume Increments, v_i (cm^3/mol)			
C	16.5	(Cl)	19.5
H	1.98	(S)	17.0
O	5.48	Aromatic ring	−20.2
(N)	5.69	Heterocyclic ring	−20.2
Diffusion Volumes for Simple Molecules, Σv_i (cm^3/mol)			
H_2	7.07	CO	18.9
D_2	6.70	CO_2	26.9
He	2.88	N_2O	35.9
N_2	17.9	NH_3	14.9
O_2	16.6	H_2O	12.7
Air	20.1	(CCl_2F_2)	114.8
Ar	16.1	(SF_5)	69.7
Kr	22.8	(Cl_2)	37.7
(Xe)	37.9	(Br_2)	67.2
Ne	5.59	(SO_2)	41.1

Parentheses indicate that the value listed is based on only a few data points.

where A = 1.06036, B = 0.15610, C = 0.1930, D = 0.47635, E = 1.03587, F = 1.52996, G = 1.76474, and H = 3.89411.

Fuller, Schettler, and Giddings [10] The parameters and constants for this correlation were determined by regression analysis of 340 experimental diffusion coefficient values of 153 binary systems. Values of $\sum v_i$ used in this equation are in Table 5-12.

Binary Mixtures—Low Pressure—Polar Components The *Brokaw* [4] correlation was based on the Chapman-Enskog equation, but σ_{AB^*} and Ω_{D^*} were evaluated with a modified Stockmayer potential for polar molecules. Hence, slightly different symbols are used. That potential model reduces to the Lennard-Jones 6-12 potential for interactions between nonpolar molecules. As a result, the method should yield accurate predictions for polar as well as nonpolar gas mixtures. Brokaw presented data for 9 relatively polar pairs along with the prediction. The agreement was good: an average absolute error of 6.4 percent, considering the complexity of some of the gas pairs [e.g., $(CH_3)_2O$ and CH_3Cl]. Despite that, Poling, (op. cit.) found the average error was 9.0 percent for combinations of mixtures (including several polar-nonpolar gas pairs), temperatures and pressures. In this equation, Ω_D is calculated as described previously, and other terms are:

$$\Omega_{D^*} = \Omega_D + 0.19\,\delta_{AB}^2/T^* \qquad T^* = kT/\varepsilon_{AB^*}$$
$$\sigma_{AB^*} = (\sigma_{A^*}\,\sigma_{B^*})^{1/2} \qquad \sigma_{i^*} = [1.585\,V_{bi}/(1 + 1.3\,\delta_i^2)]^{1/3}$$
$$\delta_{AB} = (\delta_A\,\delta_B)^{1/2} \qquad \delta_i = 1.94 \times 10^3\,\mu_i^2/V_{bi}T_{bi}$$
$$\varepsilon_{AB^*} = (\varepsilon_{A^*}\varepsilon_{B^*})^{1/2} \qquad \varepsilon_{i^*}/k = 1.18\,(1 + 1.3\,\delta_i^2)T_{bi}$$

Binary Mixtures—High Pressure Of the various categories of gas-phase diffusion, this is the least studied. This is so because of the effects of diffusion being easily distorted by even a slight pressure gradient, which is difficult to avoid at high pressure. Harstad and Bellan [*Ind. Eng. Chem. Res.* **43,** 645 (2004)] developed a corresponding-states expression that extends the Chapman-Enskog method, covered earlier. They express the diffusivity at high pressure by accounting for the reduced temperature, and they suggest employing an equation of state and shifting from $D^o_{AB} = f(T, P)$ to $D_{AB} = g(T, V)$.

Self-Diffusivity Self-diffusivity is a property that has little intrinsic value, e.g., for solving separation problems. Despite that, it reveals quite a lot about the inherent nature of molecular transport, because the effects of discrepancies of other physical properties are eliminated, except for those that constitute isotopic differences, which are necessary to ascertain composition differences. Self-diffusivity has been studied extensively under high pressures, e.g., greater than 70 atm. There are few accurate estimation methods for mutual diffusivities at such high pressures, because composition measurements are difficult.

The general observation for gas-phase diffusion $D_{AB}\,P$ = constant, which holds at low pressure, is not valid at high pressure. Rather, $D_{AB}\,P$ decreases as pressure increases. In addition, composition effects, which frequently are negligible at low pressure, are very significant at high pressure.

Liu and Ruckenstein [*Ind. Eng. Chem. Res.* **36**, 3937 (1997)] studied self-diffusion for both liquids and gases. They proposed a semiempirical equation, based on hard-sphere theory, to estimate self-diffusivities. They extended it to Lennard-Jones fluids. The necessary energy parameter is estimated from viscosity data, but the molecular collision diameter is estimated from diffusion data. They compared their estimates to 26 pairs, with a total of 1822 data points, and achieved a relative deviation of 7.3 percent.

Zielinski and Hanley [*AIChE J.* **45**, 1 (1999)] developed a model to predict multicomponent diffusivities from self-diffusion coefficients and thermodynamic information. Their model was tested by estimated experimental diffusivity values for ternary systems, predicting drying behavior of ternary systems, and reconciling ternary self-diffusion data measured by pulsed-field gradient NMR.

Mathur and Thodos [18] showed that for reduced densities less than unity, the product $D_{AA}\rho$ is approximately constant at a given temperature. Thus, by knowing the value of the product at low pressure, it is possible to estimate its value at a higher pressure. They found at higher pressures the density increases, but the product $D_{AA}\rho$ decreases rapidly. In their correlation, $\beta = M_A^{1/2}P_C^{1/3}/T_C^{5/6}$.

Lee and Thodos [14] presented a generalized treatment of self-diffusivity for gases (and liquids). These correlations have been tested for more than 500 data points each. The average deviation of the first is 0.51 percent, and that of the second is 17.2 percent. $\delta = M_A^{1/2}/P_c^{1/2}V_c^{5/6}$, s/$cm^2$, and where $G = (X^* - X)/(X^* - 1)$, $X = \rho_r/T_r^{0.1}$, and $X^* = \rho_r/T_r^{0.1}$ evaluated at the solid melting point.

Lee and Thodos [15] expanded their earlier treatment of self-diffusivity to cover 58 substances and 975 data points, with an average absolute deviation of 5.26 percent. Their correlation is too involved to repeat here, but those interested should refer to the original paper.

Liu, Silva, and Macedo [*Chem. Eng. Sci.* **53**, 2403 (1998)] present a theoretical approach incorporating hard-sphere, square-well, and Lennard-Jones models. They compared their resulting estimates to estimates generated via the Lee-Thodos equation. For 2047 data points with nonpolar species, the Lee-Thodos equation was slightly superior to the Lennard-Jones fluid-based model, that is, 5.2 percent average deviation versus 5.5 percent, and much better than the square-well fluid-based model (10.6 percent deviation). For over 467 data points with polar species, the Lee-Thodos equation yielded 36 percent average deviation, compared with 25 percent for the Lennard-Jones fluid-based model, and 19 percent for the square-well fluid-based model.

Silva, Liu, and Macedo [*Chem. Eng. Sci.* **53**, 2423 (1998)] present an improved theoretical approach incorporating slightly different Lennard-Jones models. For 2047 data points with nonpolar species, their best model yielded 4.5 percent average deviation, while the Lee-Thodos equation yielded 5.2 percent, and the prior Lennard-Jones fluid-based model produced 5.5 percent. The new model was much better than all the other models for over 424 data points with polar species, yielding 4.3 percent deviation, while the Lee-Thodos equation yielded 34 percent and the Lennard-Jones fluid-based model yielded 23 percent.

Supercritical Mixtures *Debenedetti and Reid* [*AIChE J.*, **32,** 2034 (1986) and **33,** 496 (1987)] showed that conventional correlations based on the Stokes-Einstein relation (for liquid phase) tend to overpredict diffusivities in the supercritical state. Nevertheless, they observed that the Stokes-Einstein group $D_{AB}\mu/T$ was constant. Thus, although no general correlation applies, only one data point is necessary to examine variations of fluid viscosity and/or temperature effects. They explored certain combinations of aromatic solids in SF_6 and CO_2.

Sun and Chen [25] examined tracer diffusion data of aromatic solutes in alcohols up to the supercritical range and found their data correlated with average deviations of 5 percent and a maximum deviation of 17 percent for their rather limited set of data.

Catchpole and King [6] examined binary diffusion data of near-critical fluids in the reduced density range of 1 to 2.5 and found that their data correlated with average deviations of 10 percent and a maximum deviation of 60 percent. They observed two classes of behavior. For the first, no correction factor was required (R = 1). That class was comprised of alcohols as solvents with aromatic or aliphatic solutes, or

carbon dioxide as a solvent with aliphatics except ketones as solutes, or ethylene as a solvent with aliphatics except ketones and naphthalene as solutes. For the second class, the correction factor was $R = X^{0.17}$. The class was comprised of carbon dioxide with aromatics; ketones and carbon tetrachloride as solutes; and aliphatics (propane, hexane, dimethyl butane), sulfur hexafluoride, and chlorotrifluoromethane as solvents with aromatics as solutes. In addition, sulfur hexafluoride combined with carbon tetrachloride, and chlorotrifluoromethane combined with 2-propanone were included in that class. In all cases, $X = (1 + (V_{C^B}/V_{C^A})^{1/3})^2/(1 + M_A/M_B)$ was in the range of 1 to 10.

Liu and Ruckenstein [17] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on the Stokes-Einstein relation and the long-range correlation, respectively. The parameter $2\theta^{\circ}_{AB}$ was estimated from the Peng-Robinson equation of state. In addition, $f = 2.72 - 0.3445\ T_{cB}/T_{cA}$ for most solutes, but for C_5 through C_{14} linear alkanes, $f = 3.046 - 0.786\ T_{cB}/T_{cA}$. In both cases T_{ci} is the species critical temperature. They compared their estimates to 33 pairs, with a total of 598 data points, and achieved lower deviations (5.7 percent) than the Sun-Chen correlation (13.3 percent) and the Catchpole-King equation (11.0 percent).

He and Yu [13] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on hard-sphere theory. It is limited to $\rho_r \geqslant 0.21$, where the reduced density is $\rho_r = \rho_A(T, P)/\rho_{cA}$. They compared their estimates to 107 pairs, with a total of 1167 data points, and achieved lower deviations (7.8 percent) than the Catchpole-King equation (9.7 percent), which was restricted to $\rho_r \geqslant 1$.

Silva and Macedo [*Ind. Eng. Chem. Res.* **37,** 1490 (1998)] measured diffusivities of ethers in CO_2 under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-218)], Tyn-Calus [Eq. (5-219)], Catchpole-King [Eq. (5-210)], and their own equations. They found that the Wilke-Chang equation provided the best fit.

Gonzalez, Bueno, and Medina [*Ind. Eng. Chem. Res.* **40**, 3711 (2001)] measured diffusivities of aromatic compounds in CO_2 under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-218)], Hayduk-Minhas [Eq. (5-226)], and other equations. They recommended the Wilke-Chang equation (which yielded a relative error of 10.1 percent) but noted that the He-Yu equation provided the best fit (5.5 percent).

Low-Pressure/Multicomponent Mixtures These methods are outlined in Table 5-13. Stefan-Maxwell equations were discussed earlier. *Smith and Taylor* [23] compared various methods for predicting multicomponent diffusion rates and found that Eq. (5-214) was superior among the effective diffusivity approaches, though none is very good. They also found that linearized and exact solutions are roughly equivalent and accurate.

Blanc [3] provided a simple limiting case for dilute component *i* diffusing in a stagnant medium (i.e., $N \approx 0$), and the result, Eq. (5-215), is known as Blanc's law. The restriction basically means that the compositions of all the components, besides component *i*, are relatively large and uniform.

Wilke [29] obtained solutions to the Stefan-Maxwell equations. The first, Eq. (5-216), is simple and reliable under the same conditions as Blanc's law. This equation applies when component *i* diffuses through a stagnant mixture. It has been tested and verified for diffusion of toluene in hydrogen + air + argon mixtures and for diffusion of ethyl propionate in hydrogen + air mixtures [Fairbanks and Wilke *Ind. Eng. Chem.,* **42,** 471 (1950)]. When the compositions vary from one boundary to the other, Wilke recommends that the arithmetic average mole fractions be used. Wilke also suggested using the Stefan-Maxwell equation, which applies when the fluxes of two or more components are significant. In this situation, the mole fractions are arithmetic averages of the boundary conditions, and the solution requires iteration because the ratio of fluxes is not known a priori.

DIFFUSIVITY ESTIMATION—LIQUIDS

Many more correlations are available for diffusion coefficients in the liquid phase than for the gas phase. Most, however, are restricted to binary diffusion at infinite dilution D°_{AB} or to self-diffusivity $D_{A'A}$. This reflects the much greater complexity of liquids on a molecular level. For example, gas-phase diffusion exhibits negligible composition effects and deviations from thermodynamic ideality. Conversely, liquid-phase diffusion almost always involves volumetric and thermodynamic effects due to composition variations. For concentrations greater than a few mole percent of *A* and *B,* corrections are needed to obtain the true diffusivity. Furthermore, there are many conditions that do not fit any of the correlations presented here. Thus, careful consideration is needed to produce a reasonable estimate. Again, if diffusivity data are available at the conditions of interest, then they are strongly preferred over the predictions of any correlations. Experimental values for liquid mixtures are listed in Table 2-325.

Stokes-Einstein and Free-Volume Theories The starting point for many correlations is the Stokes-Einstein equation. This equation is derived from continuum fluid mechanics and classical thermodynamics for the motion of large spherical particles in a liquid. For this case, the need for a molecular theory is cleverly avoided. The Stokes-Einstein equation is (Bird et al.)

$$D_{AB} = \frac{kT}{6\pi r_A \mu_B} \tag{5-217}$$

where *A* refers to the solute and *B* refers to the solvent. This equation is applicable to very large unhydrated molecules ($M > 1000$) in low-molecular-weight solvents or where the molar volume of the solute is greater than 500 cm^3/mol (Reddy and Doraiswamy, *Ind. Eng. Chem. Fundam.,* **6,** 77 (1967); Wilke and Chang [30]). Despite its intellectual appeal, this equation is seldom used "as is." Rather, the following principles have been identified: (1) The diffusion coefficient is inversely proportional to the size $r_A \simeq V_A^{1/3}$ of the solute molecules. Experimental observations, however, generally indicate that the exponent of the solute molar volume is larger than one-third. (2) The term $D_{AB}\mu_B/T$ is approximately constant only over a 10-to-15 K interval. Thus, the dependence of liquid diffusivity on properties and conditions does not generally obey the interactions implied by that grouping. For example, Robinson, Edmister, and Dullien [*Ind. Eng. Chem. Fundam.,* **5,** 75 (1966)] found that $\ln D_{AB} \propto -1/T$. (3) Finally, pressure does not affect liquid-phase diffusivity much, since μ_B and V_A are only weakly pressure-dependent. Pressure does have an impact at very high levels.

TABLE 5-13 Relationships for Diffusivities of Multicomponent Gas Mixtures at Low Pressure

Authors*	Equation
Stefan-Maxwell, Smith and Taylor [23]	$D_{im} = \left[1 - x_i \left(\sum_{j=1}^{NC} N_j\right)\Big/N_i\right] \Big/ \sum_{j=1}^{NC}\left[\left(x_j - \frac{x_i N_i}{N_i}\right)\Big/D_{ij}\right]$ (5-214)
Blanc [2]	$D_{im} = \left(\sum_{j=1}^{NC} \frac{x_j}{D_{ij}}\right)^{-1}$ (5-215)
Wilke [29]	$D_{im} = \left(\sum_{j=1, j\neq i}^{NC} \frac{x_j}{D_{ij}}\right)^{-1}$ (5-216)

*References are listed at the beginning of the "Mass Transfer" subsection.

Another advance in the concepts of liquid-phase diffusion was provided by Hildebrand [*Science,* **174,** 490 (1971)] who adapted a theory of viscosity to self-diffusivity. He postulated that $D_{A'A} = B(V - V_{ms})/V_{ms}$, where $D_{A'A}$ is the self-diffusion coefficient, V is the molar volume, and V_{ms} is the molar volume at which fluidity is zero (i.e., the molar volume of the solid phase at the melting temperature). The difference $(V - V_{ms})$ can be thought of as the free volume, which increases with temperature; and B is a proportionality constant.

Ertl and Dullien (ibid.) found that Hildebrand's equation could not fit their data with B as a constant. They modified it by applying an empirical exponent n (a constant greater than unity) to the volumetric ratio. The new equation is not generally useful, however, since there is no means for predicting n. The theory does identify the free volume as an important physical variable, since $n > 1$ for most liquids implies that diffusion is more strongly dependent on free volume than is viscosity.

Dilute Binary Nonelectrolytes: General Mixtures These correlations are outlined in Table 5-14.

Wilke-Chang [30] This correlation for D°_{AB} is one of the most widely used, and it is an empirical modification of the Stokes-Einstein equation. It is not very accurate, however, for water as the solute. Otherwise, it applies to diffusion of very dilute A in B. The average absolute error for 251 different systems is about 10 percent. ϕ_B is an association factor of solvent B that accounts for hydrogen bonding.

Component B	ϕ_B
Water	2.26
Methanol	1.9
Ethanol	1.5
Propanol	1.2
Others	1.0

The value of ϕ_B for water was originally stated as 2.6, although when the original data were reanalyzed, the empirical best fit was 2.26. Random comparisons of predictions with 2.26 versus 2.6 show no consistent advantage for either value, however. Kooijman [*Ind. Eng. Chem. Res.* **41,** 3326 (2002)] suggests replacing V_A with $\theta_A V_A$, in which $\theta_A = 1$ except when A = water, $\theta_A = 4.5$. This modification leads to an overall error of 8.7 percent for 41 cases he compared. He suggests retaining $\Phi_B = 2.6$ when B = water. It has been suggested to replace the exponent of 0.6 with 0.7 and to use an association factor of 0.7 for systems containing aromatic hydrocarbons. These modifications, however, are not recommended by Umesi and Danner [27]. Lees and Sarram [*J. Chem. Eng. Data,* **16,** 41 (1971)] present a comparison of the association parameters. The average absolute error for 87 different solutes in water is 5.9 percent.

Tyn-Calus [26] This correlation requires data in the form of molar volumes and parachors $\psi_i = V_i\sigma_i^{1/4}$ (a property which, over moderate temperature ranges, is nearly constant), measured at the same temperature (not necessarily the temperature of interest). The parachors for the components may also be evaluated at different temperatures from each other. Quale [Chem. Rev. **53,** 439 (1953)] has compiled values of ψ_i for many chemicals. Group contribution methods are available for estimation purposes (Poling et al.). The following suggestions were made by Poling et al.: The correlation is constrained to cases in which $\mu_B < 30$ cP. If the solute is water or if the solute is an organic acid and the solvent is not water or a short-chain alcohol, dimerization of the solute A should be assumed for purposes of estimating its volume and parachor. For example, the appropriate values for water as solute at 25°C are $V_W = 37.4$ cm^3/mol and $\psi_W = 105.2$ cm^{3}g$^{1/4}$/s$^{1/2}$mol. Finally, if the solute is nonpolar, the solvent volume and parachor should be multiplied by $8\mu_B$. According to Kooijman (ibid.), if the Brock-Bird method (described in Poling et al.) is used to

TABLE 5-14 Correlations for Diffusivities of Dilute, Binary Mixtures of Nonelectrolytes in Liquids

Authors*	Equation		Error
1. General Mixtures			
Wilke-Chang [30]	$D^\circ_{AB} = \dfrac{7.4 \times 10^{-8}\,(\phi_B M_B)^{1/2}\,T}{\mu_B\,V_A^{0.6}}$	(5-218)	20%
Tyn-Calus [26]	$D^\circ_{AB} = \dfrac{8.93 \times 10^{-8}\,(V_A/V_B^2)^{1/6}\,(\psi_B/\psi_A)^{0.6}\,T}{\mu_B}$	(5-219)	10%
Umesi-Danner [27]	$D^\circ_{AB} = \dfrac{2.75 \times 10^{-8}\,(R_B/R_A^{2/3})\,T}{\mu_B}$	(5-220)	16%
Siddiqi-Lucas [22]	$D^\circ_{AB} = \dfrac{9.89 \times 10^{-8}\,V_B^{0.265}\,T}{V_A^{0.45}\,\mu_B^{0.907}}$	(5-221)	13%
2. Gases in Low Viscosity Liquids			
Sridhar-Potter [24]	$D^\circ_{AB} = D_{BB}\left(\dfrac{V_{c_B}}{V_{c_A}}\right)^{2/3}\left(\dfrac{V_B}{V_{ml_B}}\right)$	(5-222)	18%
Chen-Chen [7]	$D^\circ_{AB} = 2.018 \times 10^{-9}\,\dfrac{(\beta V_{c_B})^{2/3}(RT_{c_B})^{1/2}}{M_A^{1/6}\,(M_B V_{c_A})^{1/3}}\,(V_r - 1)\left(\dfrac{T}{T_{c_B}}\right)^{1/2}$	(5-223)	6%
3. Aqueous Solutions			
Hayduk-Laudie [11]	$D^\circ_{AW} = \dfrac{13.16 \times 10^{-5}}{\mu_w^{1.14}\,V_A^{0.589}}$	(5-224)	18%
Siddiqi-Lucas [22]	$D^\circ_{AW} = 2.98 \times 10^{-7}\,V_A^{-0.5473}\,\mu_w^{-1.026}\,T$	(5-225)	13%
4. Hydrocarbon Mixtures			
Hayduk-Minhas [12]	$D^\circ_{AB} = 13.3 \times 10^{-8}\,T^{1.47}\,\mu_B^{(10.2/V_A - 0.791)}\,V_A^{-0.71}$	(5-226)	5%
Matthews-Akgerman [19]	$D^\circ_{AB} = 32.88\,M_A^{-0.61}V_D^{-1.04}\,T^{0.5}\,(V_B - V_D)$	(5-227)	5%
Riazi-Whitson [21]	$D_{AB} = 1.07\,\dfrac{(\rho D_{AB})^\circ}{\rho}\left(\dfrac{\mu}{\mu^\circ}\right)^{-0.27 - 0.38\,\omega + (-0.05 + 0.1\,\omega)P_r}$	(5-228)	15%

*References are listed at the beginning of the "Mass Transfer" subsection.

estimate the surface tension, the error is only increased by about 2 percent, relative to employing experimentally measured values.

Umesi-Danner [27] They developed an equation for nonaqueous solvents with nonpolar and polar solutes. In all, 258 points were involved in the regression. R_i is the radius of gyration in Å of the component molecule, which has been tabulated by Passut and Danner [*Chem. Eng. Progress Symp. Ser.,* **140,** 30 (1974)] for 250 compounds. The average absolute deviation was 16 percent, compared with 26 percent for the Wilke-Chang equation.

Siddiqi-Lucas [22] In an impressive empirical study, these authors examined 1275 organic liquid mixtures. Their equation yielded an average absolute deviation of 13.1 percent, which was less than that for the Wilke-Chang equation (17.8 percent). Note that this correlation does not encompass aqueous solutions; those were examined and a separate correlation was proposed, which is discussed later.

Binary Mixtures of Gases in Low-Viscosity, Nonelectrolyte Liquids *Sridhar and Potter* [24] derived an equation for predicting gas diffusion through liquid by combining existing correlations. Hildebrand had postulated the following dependence of the diffusivity for a gas in a liquid: $D^\circ_{AB} = D_{B'B}(V_{cB}/V_{cA})^{2/3}$, where $D_{B'B}$ is the solvent self-diffusion coefficient and V_{ci} is the critical volume of component i, respectively. To correct for minor changes in volumetric expansion, Sridhar and Potter multiplied the resulting equation by V_B/V_{ml_B}, where V_{ml_B} is the molar volume of the liquid B at its melting point and $D_{B'B}$ can be estimated by the equation of Ertl and Dullien (see p. 5-54). Sridhar and Potter compared experimentally measured diffusion coefficients for twenty-seven data points of eleven binary mixtures. Their average absolute error was 13.5 percent, but Chen and Chen [7] analyzed about 50 combinations of conditions and 3 to 4 replicates each and found an average error of 18 percent. This correlation does not apply to hydrogen and helium as solutes. However, it demonstrates the usefulness of self-diffusion as a means to assess mutual diffusivities and the value of observable physical property changes, such as molar expansion, to account for changes in conditions.

Chen-Chen [7] Their correlation was based on diffusion measurements of 50 combinations of conditions with 3 to 4 replicates each and exhibited an average error of 6 percent. In this correlation, $V_r = V_B/[0.9724\,(V_{ml_B} + 0.04765)]$ and V_{ml_B} = the liquid molar volume at the melting point, as discussed previously. Their association parameter β [which is different from the definition of that symbol in Eq. (5-229)] accounts for hydrogen bonding of the solvent. Values for acetonitrile and methanol are: β = 1.58 and 2.31, respectively.

Dilute Binary Mixtures of a Nonelectrolyte in Water The correlations that were suggested previously for general mixtures, unless specified otherwise, may also be applied to diffusion of miscellaneous solutes in water. The following correlations are restricted to the present case, however.

Hayduk and Laudie [11] They presented a simple correlation for the infinite dilution diffusion coefficients of nonelectrolytes in water. It has about the same accuracy as the Wilke-Chang equation (about 5.9 percent). There is no explicit temperature dependence, but the 1.14 exponent on μ_w compensates for the absence of T in the numerator. That exponent was misprinted (as 1.4) in the original article and has been reproduced elsewhere erroneously.

Siddiqi and Lucas [227] These authors examined 658 aqueous liquid mixtures in an empirical study. They found an average absolute deviation of 19.7 percent. In contrast, the Wilke-Chang equation gave 35.0 percent and the Hayduk-Laudie correlation gave 30.4 percent.

Dilute Binary Hydrocarbon Mixtures *Hayduk and Minhas* [12] presented an accurate correlation for normal paraffin mixtures that was developed from 58 data points consisting of solutes from C_5 to C_{32} and solvents from C_5 to C_{16}. The average error was 3.4 percent for the 58 mixtures.

Matthews and Akgerman [19] The free-volume approach of Hildebrand was shown to be valid for binary, dilute liquid paraffin mixtures (as well as self-diffusion), consisting of solutes from C_8 to C_{16} and solvents of C_6 and C_{12}. The term they referred to as the "diffusion volume" was simply correlated with the critical volume, as $V_D = 0.308\ V_c$. We can infer from Table 5-11 that this is approximately related to the volume at the melting point as $V_D = 0.945\ V_m$. Their correlation was valid for diffusion of linear alkanes at temperatures up to 300°C and pressures up to 3.45 MPa. Matthews, Rodden, and Akgerman [*J. Chem. Eng. Data,* **32,** 317 (1987)] and Erkey and Akgerman [*AIChE J.,* **35,** 443 (1989)] completed similar studies of diffusion of alkanes, restricted to *n*-hexadecane and *n*-octane, respectively, as the solvents.

Riazi and Whitson [21] They presented a generalized correlation in terms of viscosity and molar density that was applicable to both gases and liquids. The average absolute deviation for gases was only about 8 percent, while for liquids it was 15 percent. Their expression relies on the Chapman-Enskog correlation [Eq. (5-202)] for the low-pressure diffusivity and the Stiel-Thodos [*AIChE J.,* **7,** 234 (1961)] correlation for low-pressure viscosity:

$$\mu^\circ = \frac{x_A\mu^\circ_A M_A^{1/2} + x_B\mu^\circ_B M_B^{1/2}}{x_A M_A^{1/2} + x_B M_B^{1/2}}$$

where $\mu^\circ_i\xi_i = 3.4 \times 10^{-4}\ T_{ri}^{0.94}$ for $T_{ri} < 1.5$ or $\mu^\circ_i\xi_i = 1.778 \times 10^{-4}\ (4.58\ T_{ri} - 1.67)^{5/8}$ for $T_{ri} > 1.5$. In these equations, $\xi_i = T_{ci}^{1/6}/P_{ci}^{2/3}\ M_i^{1/2}$, and units are in cP, atm, K, and mol. For dense gases or liquids, the Chung et al; [*Ind. Eng. Chem. Res.,* **27,** 671 (1988)] or Jossi-Stiel-Thodos [*AIChE J.,* **8,** 59 (1962)] correlation may be used to estimate viscosity. The latter is:

$$(\mu - \mu^\circ)\ \xi + 10^{-4} = (0.1023 + 0.023364\ \rho_r + 0.058533\ \rho_r^2 - 0.040758\ \rho_r^3 + 0.093324\ \rho_r^4)^4$$

where $$\xi = \frac{(x_A\ T_{c_A} + x_B T_{c_B})^{1/6}}{(x_A M_A + x_B M_B)^{1/2}\ (x_A\ P_{c_A} + x_B\ P_{c_B})}$$

and $$\rho_r = (x_A\ V_{c_A} + x_B\ V_{c_B})\rho.$$

Dilute Binary Mixtures of Nonelectrolytes with Water as the Solute *Olander* [*AIChE J.,* **7,** 175 (1961)] modified the Wilke-Chang equation to adapt it to the infinite dilution diffusivity of water as the solute. The modification he recommended is simply the division of the right-hand side of the Wilke-Chang equation by 2.3. Unfortunately, neither the Wilke-Chang equation nor that equation divided by 2.3 fit the data very well. A reasonably valid generalization is that the Wilke-Chang equation is accurate if water is very insoluble in the solvent, such as pure hydrocarbons, halogenated hydrocarbons, and nitro-hydrocarbons. On the other hand, the Wilke-Chang equation divided by 2.3 is accurate for solvents in which water is very soluble, as well as those that have low viscosities. Such solvents include alcohols, ketones, carboxylic acids, and aldehydes. Neither equation is accurate for higher-viscosity liquids, especially diols.

Dilute Dispersions of Macromolecules in Nonelectrolytes The Stokes-Einstein equation has already been presented. It was noted that its validity was restricted to large solutes, such as spherical macromolecules and particles in a continuum solvent. The equation has also been found to predict accurately the diffusion coefficient of spherical latex particles and globular proteins. Corrections to Stokes-Einstein for molecules approximating spheroids is given by Tanford *Physical Chemistry of Macromolecules,* Wiley, New York, (1961). Since solute-solute interactions are ignored in this theory, it applies in the dilute range only.

Hiss and Cussler [AIChE J., ***19,*** *698 (1973)]* Their basis is the diffusion of a small solute in a fairly viscous solvent of relatively large molecules, which is the opposite of the Stokes-Einstein assumptions. The large solvent molecules investigated were not polymers or gels but were of moderate molecular weight so that the macroscopic and microscopic viscosities were the same. The major conclusion is that $D^\circ_{AB}\ \mu^{2/3}$ = constant at a given temperature and for a solvent viscosity from 5×10^{-3} to 5 Pa·s or greater (5 to 5×10^3 cP). This observation is useful if D°_{AB} is known in a given high-viscosity liquid (oils, tars, etc.). Use of the usual relation of $D^\circ_{AB} \propto 1/\mu$ for such an estimate could lead to large errors.

Concentrated, Binary Mixtures of Nonelectrolytes Several correlations that predict the composition dependence of D_{AB} are summarized in Table 5-15. Most are based on known values of D°_{AB} and D°_{BA}. In fact, a rule of thumb states that, for many binary systems, D°_{AB} and D°_{BA} bound the D_{AB} vs. x_A curve. Cullinan's [8] equation predicts diffusivities even in lieu of values at infinite dilution, but requires accurate density, viscosity, and activity coefficient data.

TABLE 5-15 Correlations of Diffusivities for Concentrated, Binary Mixtures of Nonelectrolyte Liquids

Authors*	Equation	
Caldwell-Babb [5]	$D_{AB} = (x_A D^\circ_{BA} + x_B D^\circ_{AB})\beta_A$	(5-231)
Rathbun-Babb [20]	$D_{AB} = (x_A D^\circ_{BA} + x_B D^\circ_{AB})\beta_A^n$	(5-232)
Vignes [28]	$D_{AB} = D^{\circ x_B}_{AB} D^{\circ x_A}_{BA} \beta_A$	(5-233)
Leffler-Cullinan [16]	$D_{AB}\mu_{mix} = (D^\circ_{AB}\mu_B)^{x_B}(D^\circ_{BA}\mu_A)^{x_A}\beta_A$	(5-234)
Cussler [9]	$D_{AB} = D_0\left[1 + \frac{K}{x_A x_B}\left(\frac{\partial \ln x_A}{\partial \ln a_A} - 1\right)\right]^{-1/2}$	(5-235)
Cullinan [8]	$D_{AB} = \frac{kT}{2\pi\mu_{mix}(V/A)^{1/3}}\left[\frac{2\pi x_A x_B \beta_A}{1 + \beta_A(2\pi x_A x_B - 1)}\right]^{1/2}$	(5-236)
Asfour-Dullien [1]	$D_{AB} = \left(\frac{D^\circ_{AB}}{\mu_B}\right)^{x_B}\left(\frac{D^\circ_{BA}}{\mu_A}\right)^{x_A}\zeta\mu\beta_A$	(5-237)
Siddiqi-Lucas [22]	$D_{AB} = (C_B \overline{V}_B D^\circ_{AB} + C_A \overline{V}_A D^\circ_{BA})\beta_A$	(5-238)
Bosse and Bart no. 1 [3]	$D_{AB} = (D^\infty_{AB})^{X_B}(D^\infty_{AB})^{X_A}\exp\left(-\frac{g^E}{RT}\right)$	(5-239)
Bosse and Bart no. 2 [3]	$\mu D_{AB} = (\mu_\beta D^\infty_{AB})^{X_B}(\mu_A D^\infty_{BA})^{X_A}\exp\left(-\frac{g^E}{RT}\right)$	(5-240)

Relative errors for the correlations in this table are very dependent on the components of interest and are cited in the text.
*See the beginning of the "Mass Transfer" subsection for references.

Since the infinite dilution values D°_{AB} and D°_{BA} are generally unequal, even a thermodynamically ideal solution like $\gamma_A = \gamma_B = 1$ will exhibit concentration dependence of the diffusivity. In addition, nonideal solutions require a thermodynamic correction factor to retain the true "driving force" for molecular diffusion, or the gradient of the chemical potential rather than the composition gradient. That correction factor is:

$$\beta_A = 1 + \frac{\partial \ln \gamma_A}{\partial \ln x_A} \qquad (5\text{-}229)$$

Caldwell and Babb [5] Darken [*Trans. Am. Inst. Mining Met. Eng.*, **175,** 184 (1948)] observed that solid-state diffusion in metallurgical applications followed a simple relation. His equation related the tracer diffusivities and mole fractions to the mutual diffusivity:

$$D_{AB} = (x_A D_B + x_B D_A)\beta_A \qquad (5\text{-}230)$$

Caldwell and Babb used virtually the same equation to evaluate the mutual diffusivity for concentrated mixtures of common liquids.

Van Geet and Adamson [*J. Phys. Chem.* **68,** 238 (1964)] tested that equation for the *n*-dodecane (*A*) and *n*-octane (*B*) system and found the average deviation of D_{AB} from experimental values to be −0.68 percent. In addition, that equation was tested for benzene + bromobenzene, *n*-hexane + *n*-dodecane, benzene + CCl_4, octane + decane, heptane + cetane, benzene + diphenyl, and benzene + nitromethane with success. For systems that depart significantly from thermodynamic ideality, it breaks down, sometimes by a factor of eight. For example, in the binary systems acetone + CCl_4, acetone + chloroform, and ethanol + CCl_4, it is not accurate. Thus, it can be expected to be fairly accurate for nonpolar hydrocarbons of similar molecular weight but not for polar-polar mixtures. Siddiqi, Krahn, and Lucas [*J. Chem. Eng. Data*, **32,** 48 (1987)] found that this relation was superior to those of Vignes and Leffler and Cullinan for a variety of mixtures. Umesi and Danner [27] found an average absolute deviation of 13.9 percent for 198 data points.

Rathbun and Babb [20] suggested that Darken's equation could be improved by raising the thermodynamic correction factor β_A to a power, *n,* less than unity. They looked at systems exhibiting negative deviations from Raoult's law and found $n = 0.3$. Furthermore, for polar-nonpolar mixtures, they found $n = 0.6$. In a separate study, Siddiqi and Lucas [22] followed those suggestions and found an average absolute error of 3.3 percent for nonpolar-nonpolar mixtures, 11.0 percent for polar-nonpolar mixtures, and 14.6 percent for polar-polar mixtures. Siddiqi, Krahn, and Lucas (ibid.) examined a few other mixtures and found that $n = 1$ was probably best. Thus, this approach is, at best, highly dependent on the type of components being considered.

Vignes [28] empirically correlated mixture diffusivity data for 12 binary mixtures. Later Ertl, Ghai, and Dollon [*AIChE J.*, **20,** 1 (1974)] evaluated 122 binary systems, which showed an average absolute deviation of only 7 percent. None of the latter systems, however, was very nonideal.

Leffler and Cullinan [16] modified Vignes' equation using some theoretical arguments to arrive at Eq. (5-234), which the authors compared to Eq. (5-233) for the 12 systems mentioned above. The average absolute maximum deviation was only 6 percent. Umesi and Danner [27], however, found an average absolute deviation of 11.4 percent for 198 data points. For normal paraffins, it is not very accurate. In general, the accuracies of Eqs. (5-233) and (5-234) are not much different, and since Vignes' is simpler to use, it is suggested. The application of either should be limited to nonassociating systems that do not deviate much from ideality ($0.95 < \beta_A < 1.05$).

Cussler [9] studied diffusion in concentrated associating systems and has shown that, in associating systems, it is the size of diffusing clusters rather than diffusing solutes that controls diffusion. D_o is a reference diffusion coefficient discussed hereafter; a_A is the activity of component *A*; and *K* is a constant. By assuming that D_o could be predicted by Eq. (5-233) with $\beta = 1$, *K* was found to be equal to 0.5 based on five binary systems and validated with a sixth binary mixture. The limitations of Eq. (5-235) using D_o and *K* defined previously have not been explored, so caution is warranted. Gurkan [*AIChE J.*, **33,** 175 (1987)] showed that *K* should actually be closer to 0.3 (rather than 0.5) and discussed the overall results.

Cullinan [8] presented an extension of Cussler's cluster diffusion theory. His method accurately accounts for composition and temperature dependence of diffusivity. It is novel in that it contains no adjustable constants, and it relates transport properties and solution thermodynamics. This equation has been tested for six very different mixtures by Rollins and Knaebel [*AIChE J.*, **37,** 470 (1991)], and it was found to agree remarkably well with data for most conditions, considering the absence of adjustable parameters. In the dilute region (of either *A* or *B*), there are systematic errors probably caused by the breakdown of certain implicit assumptions (that nevertheless appear to be generally valid at higher concentrations).

Asfour and Dullien [1] developed a relation for predicting alkane diffusivities at moderate concentrations that employs:

$$\zeta = \left(\frac{V_{f_m}}{V_{f_{x_A}} V_{f_{x_B}}}\right)^{2/3} \frac{M_{x_A} M_{x_B}}{M_m} \qquad (5\text{-}241)$$

where $V_{fx_i} = V_{fi}^{x_i}$; the fluid free volume is $V_{f^i} = V_i - V_{ml^i}$ for $i = A, B,$ and m, in which V_{ml^i} is the molar volume of the liquid at the melting point and

$$V_{ml_m} = \left(\frac{x_A^2}{V_{ml_A}} + \frac{2x_A x_B}{V_{ml_{AB}}} + \frac{x_B^2}{V_{ml_B}}\right)^{-1}$$

and

$$V_{ml_{AB}} = \left[\frac{V_{ml_A}^{1/3} + V_{ml_B}^{1/3}}{2}\right]^3$$

and μ is the mixture viscosity; M_m is the mixture mean molecular weight; and β_A is defined by Eq. (5-229). The average absolute error of this equation is 1.4 percent, while the Vignes equation and the Leffler-Cullinan equation give 3.3 percent and 6.2 percent, respectively.

Siddiqi and Lucas [22] suggested that component volume fractions might be used to correlate the effects of concentration dependence. They found an average absolute deviation of 4.5 percent for nonpolar-nonpolar mixtures, 16.5 percent for polar-nonpolar mixtures, and 10.8 percent for polar-polar mixtures.

Bosse and Bart added a term to account for excess Gibbs free energy, involved in the activation energy for diffusion, which was previously omitted. Doing so yielded minor modifications of the Vignes and Leffler-Cullinan equations [Eqs. (5-233) and (5-234), respectively]. The UNIFAC method was used to assess the excess Gibbs free energy. Comparing predictions of the new equations with data for 36 pairs and 326 data points yielded relative deviations of 7.8 percent and 8.9 percent, respectively, but which were better than the closely related Vignes (12.8 percent) and Leffler-Cullinan (10.4 percent) equations.

Binary Electrolyte Mixtures When electrolytes are added to a solvent, they dissociate to a certain degree. It would appear that the solution contains at least three components: solvent, anions, and cations. If the solution is to remain neutral in charge at each point (assuming the absence of any applied electric potential field), the anions and cations diffuse effectively as a single component, as for molecular diffusion. The diffusion of the anionic and cationic species in the solvent can thus be treated as a binary mixture.

Nernst-Haskell The theory of dilute diffusion of salts is well developed and has been experimentally verified. For dilute solutions of a single salt, the well-known Nernst-Haskell equation (Poling et al.) is applicable:

$$D_{AB}^{\circ} = \frac{RT}{F^2}\,\frac{\left|\frac{1}{n_+}\right| + \left|\frac{1}{n_-}\right|}{\frac{1}{\lambda_+^0} + \frac{1}{\lambda_-^0}} = 8.9304 \times 10^{-10}\, T\, \frac{\left|\frac{1}{n_+}\right| + \left|\frac{1}{n_-}\right|}{\frac{1}{\lambda_+^0} + \frac{1}{\lambda_-^0}} \qquad (5\text{-}242)$$

where D_{AB}° = diffusivity based on molarity rather than normality of dilute salt A in solvent B, cm²/s.

The previous definitions can be interpreted in terms of ionic-species diffusivities and conductivities. The latter are easily measured and depend on temperature and composition. For example, the equivalent conductance Λ is commonly tabulated in chemistry handbooks as the limiting (infinite dilution) conductance Λ_o and at standard concentrations, typically at 25°C. $\Lambda = 1000K/C = \lambda_+ + \lambda_- = \Lambda_o + f(C)$, (cm²/ohm gequiv); $K = \alpha/\boldsymbol{R}$ = specific conductance, (ohm cm)$^{-1}$; C = solution concentration, (gequiv/ℓ); α = conductance cell constant (measured), (cm^{-1}); $\boldsymbol{R}$ = solution electrical resistance, which is measured (ohm); and $f(C)$ = a complicated function of concentration. The resulting equation of the electrolyte diffusivity is

$$D_{AB} = \frac{|z_+| + |z_-|}{(|z_-| / D_+) + (|z_+| / D_-)} \qquad (5\text{-}243)$$

where $|z_\pm|$ represents the magnitude of the ionic charge and where the cationic or anionic diffusivities are $D_\pm = 8.9304 \times 10^{-10}\, T\lambda_\pm/|z_\pm|$ cm²/s. The coefficient is $kN_0/F^2 = R/F^2$. In practice, the equivalent conductance of the ion pair of interest would be obtained and supplemented with conductances of permutations of those ions and one independent cation and anion. This would allow determination of all the ionic conductances and hence the diffusivity of the electrolyte solution.

Gordon [J. Phys. Chem. **5,** *522 (1937)*] Typically, as the concentration of a salt increases from infinite dilution, the diffusion coefficient decreases rapidly from D_{AB}°. As concentration is increased further, however, D_{AB} rises steadily, often becoming greater than D_{AB}°. Gordon proposed the following empirical equation, which is applicable up to concentrations of 2N:

$$D_{AB} = D_{AB}^{\circ}\,\frac{1}{C_B \bar{V}_B}\,\frac{\mu_B}{\mu}\left(1 + \frac{\ln \gamma_\pm}{\ln m}\right) \qquad (5\text{-}244)$$

where D_{AB}° is given by the Nernst-Haskell equation. References that tabulate $\gamma_\pm$ as a function of m, as well as other equations for D_{AB}, are given by Poling et al.

Morgan, Ferguson, and Scovazzo [Ind. Eng. Chem. Res. ***44,*** *4815 (2005)*] They studied diffusion of gases in ionic liquids having moderate to high viscosity (up to about 1000 cP) at 30°C. Their range was limited, and the empirical equation they found was

$$D_{AB} = 3.7 \times 10^{-3}\left(\frac{1}{\mu_B^{0.59} V_A \rho_B^2}\right) \qquad (5\text{-}245)$$

which yielded a correlation coefficient of 0.975. Of the estimated diffusivities 90 percent were within ±20 percent of the experimental values. The exponent for viscosity approximately confirmed the observation of Hiss and Cussler (ibid).

Multicomponent Mixtures No simple, practical estimation methods have been developed for predicting multicomponent liquid-diffusion coefficients. Several theories have been developed, but the necessity for extensive activity data, pure component and mixture volumes, mixture viscosity data, and tracer and binary diffusion coefficients have significantly limited the utility of the theories (see Poling et al.).

The generalized Stefan-Maxwell equations using binary diffusion coefficients are not easily applicable to liquids since the coefficients are so dependent on conditions. That is, in liquids, each D_{ij} can be strongly composition dependent in binary mixtures and, moreover, the binary D_{ij} is strongly affected in a multicomponent mixture. Thus, the convenience of writing multicomponent flux equations in terms of binary coefficients is lost. Conversely, they apply to gas mixtures because each D_{ij} is practically independent of composition by itself and in a multicomponent mixture (see Taylor and Krishna for details).

One particular case of multicomponent diffusion that has been examined is the dilute diffusion of a solute in a homogeneous mixture (e.g., of A in $B + C$). Umesi and Danner [27] compared the three equations given below for 49 ternary systems. All three equations were equivalent, giving average absolute deviations of 25 percent.

Perkins and Geankoplis [Chem. Eng. Sci., ***24,*** *1035 (1969)*]

$$D_{am}\,\mu_m^{0.8} = \sum_{\substack{j=1 \\ j \neq A}}^{n} x_j\, D_{Aj}^{\circ}\, \mu_j^{0.8} \qquad (5\text{-}246)$$

Cullinan [Can. J. Chem. Eng. ***45,*** *377 (1967)*] This is an extension of Vignes' equation to multicomponent systems:

$$D_{am} = \prod_{\substack{j=1 \\ j \neq A}}^{n} (D_{Aj}^{\circ})^{x_j} \qquad (5\text{-}247)$$

Leffler and Cullinan [16] They extended their binary relation to an arbitrary multicomponent mixture, as follows:

$$D_{am}\,\mu_m = \prod_{\substack{j=1 \\ j \neq A}}^{n} (D_{Aj}^{\circ}\,\mu_j)^{x_j} \qquad (5\text{-}248)$$

where D_{Aj} is the dilute binary diffusion coefficient of A in j; D_{Am} is the dilute diffusion of A through m; x_j is the mole fraction; μ_j is the viscosity of component j; and μ_m is the mixture viscosity.

Akita [Ind. Eng. Chem. Fundam., ***10,*** *89 (1981)*] Another case of multicomponent dilute diffusion of significant practical interest is that of gases in aqueous electrolyte solutions. Many gas-absorption processes use electrolyte solutions. Akita presents experimentally tested equations for this case.

Graham and Dranoff [Ind. Eng. Chem. Fundam., ***21,*** *360 and 365 (1982)*] They studied multicomponent diffusion of electrolytes in ion exchangers. They found that the Stefan-Maxwell interaction coefficients reduce to limiting ion tracer diffusivities of each ion.

Pinto and Graham *[AIChE J.* ***32,*** *291 (1986) and* ***33,*** *436 (1987)]* They studied multicomponent diffusion in electrolyte solutions. They focused on the Stefan-Maxwell equations and corrected for solvation effects. They achieved excellent results for 1-1 electrolytes in water at 25°C up to concentrations of 4*M*.

Anderko and Lencka *[Ind. Eng. Chem. Res.* ***37,*** *2878 (1998)]* These authors present an analysis of self-diffusion in multicomponent aqueous electrolyte systems. Their model includes contributions of long-range (Coulombic) and short-range (hard-sphere) interactions. Their mixing rule was based on equations of nonequilibrium thermodynamics. The model accurately predicts self-diffusivities of ions and gases in aqueous solutions from dilute to about 30 mol/kg water. It makes it possible to take single-solute data and extend them to multicomponent mixtures.

DIFFUSION OF FLUIDS IN POROUS SOLIDS

Diffusion in porous solids is usually the most important factor controlling mass transfer in adsorption, ion exchange, drying, heterogeneous catalysis, leaching, and many other applications. Some of the applications of interest are outlined in Table 5-16. Applications of these equations are found in Secs. 16, 22, and 23.

Diffusion within the largest cavities of a porous medium is assumed to be similar to ordinary or bulk diffusion except that it is hindered by the pore walls (see Eq. 5-249). The tortuosity τ that expresses this hindrance has been estimated from geometric arguments. Unfortunately, measured values are often an order of magnitude greater than those estimates. Thus, the effective diffusivity D_{eff} (and hence τ) is normally determined by comparing a diffusion model to experimental measurements. The normal range of tortuosities for silica gel, alumina, and other porous solids is $2 \le \tau \le 6$, but for activated carbon, $5 \le \tau \le 65$.

In small pores and at low pressures, the mean free path ℓ of the gas molecule (or atom) is significantly greater than the pore diameter d_{pore}. Its magnitude may be estimated from

$$\ell = \frac{3.2\,\mu}{P}\left(\frac{RT}{2\pi M}\right)^{1/2} \quad \text{m}$$

As a result, collisions with the wall occur more frequently than with other molecules. This is referred to as the Knudsen mode of diffusion and is contrasted with ordinary or bulk diffusion, which occurs by intermolecular collisions. At intermediate pressures, both ordinary diffusion and Knudsen diffusion may be important [see Eqs. (5-252) and (5-253)].

For gases and vapors that adsorb on the porous solid, surface diffusion may be important, particularly at high surface coverage [see Eqs. (5-254) and (5-257)]. The mechanism of surface diffusion may be viewed as molecules hopping from one surface site to another. Thus, if adsorption is too strong, surface diffusion is impeded, while if adsorption is too weak, surface diffusion contributes insignificantly to the overall rate. Surface diffusion and bulk diffusion usually occur in parallel [see Eqs. (5-258) and (5-259)]. Although D_s is expected to be less than D_{eff}, the solute flux due to surface diffusion may be larger

*See the beginning of the "Mass Transfer" subsection for references.

than that due to bulk diffusion if $\partial q_i/\partial z >> \partial C_i/\partial z$. This can occur when a component is strongly adsorbed and the surface coverage is high. For all that, surface diffusion is not well understood. The references in Table 5-16 should be consulted for further details.

INTERPHASE MASS TRANSFER

Transfer of material between phases is important in most separation processes in which two phases are involved. When one phase is pure, mass transfer in the pure phase is not involved. For example, when a pure liquid is being evaporated into a gas, only the gas-phase mass transfer need be calculated. Occasionally, mass transfer in one of the two phases may be neglected even though pure components are not involved. This will be the case when the resistance to mass transfer is much larger in one phase than in the other. Understanding the nature and magnitudes of these resistances is one of the keys to performing reliable mass transfer. In this section, mass transfer between gas and liquid phases will be discussed. The principles are easily applied to the other phases.

Mass-Transfer Principles: Dilute Systems When material is transferred from one phase to another across an interface that separates the two, the resistance to mass transfer in each phase causes a concentration gradient in each, as shown in Fig. 5-26 for a gas-liquid interface. The concentrations of the diffusing material in the two phases immediately adjacent to the interface generally are unequal, even if expressed in the same units, but usually are assumed to be related to each other by the laws of thermodynamic equilibrium. Thus, it is assumed that the thermodynamic equilibrium is reached at the gas-liquid interface almost immediately when a gas and a liquid are brought into contact.

For systems in which the solute concentrations in the gas and liquid phases are dilute, the rate of transfer may be expressed by equations which predict that the rate of mass transfer is proportional to the difference between the bulk concentration and the concentration at the gas-liquid interface. Thus

$$N_A = k'_G(p - p_i) = k'_L(c_i - c) \tag{5-261}$$

where N_A = mass-transfer rate, k'_G = gas-phase mass-transfer coefficient, k'_L = liquid-phase mass-transfer coefficient, p = solute partial pressure in bulk gas, p_i = solute partial pressure at interface, c = solute concentration in bulk liquid, and c_i = solute concentration in liquid at interface.

The mass-transfer coefficients k'_G and k'_L by definition are equal to the ratios of the molal mass flux N_A to the concentration driving forces $(p - p_i)$ and $(c_i - c)$ respectively. An alternative expression for the rate of transfer in dilute systems is given by

$$N_A = k_G(y - y_i) = k_L(x_i - x) \tag{5-262}$$

where N_A = mass-transfer rate, k_G = gas-phase mass-transfer coefficient, k_L = liquid-phase mass-transfer coefficient, y = mole-fraction solute in bulk-gas phase, y_i = mole-fraction solute in gas at interface, x = mole-fraction solute in bulk-liquid phase, and x_i = mole-fraction solute in liquid at interface.

The mass-transfer coefficients defined by Eqs. (5-261) and (5-262) are related to each other as follows:

$$k_G = k'_G p_T \tag{5-263}$$

$$k_L = k'_L \bar{\rho}_L \tag{5-264}$$

where p_T = total system pressure employed *during the experimental determinations* of k'_G values and $\bar{\rho}_L$ = average molar density of the liquid phase. The coefficient k_G is relatively independent of the total system pressure and therefore is more convenient to use than k'_G, which is inversely proportional to the total system pressure.

The above equations may be used for finding the interfacial concentrations corresponding to any set of values of x and y provided the ratio of the individual coefficients is known. Thus

$$(y - y_i)/(x_i - x) = k_L/k_G = k'_L\bar{\rho}_L/k'_G p_T = L_M H_G/G_M H_L \tag{5-265}$$

where L_M = molar liquid mass velocity, G_M = molar gas mass velocity, H_L = height of one transfer unit based on liquid-phase resistance, and H_G = height of one transfer unit based on gas-phase resistance. The last term in Eq. (5-265) is derived from Eqs. (5-284) and (5-286).

Equation (5-265) may be solved graphically if a plot is made of the equilibrium vapor and liquid compositions and a point representing the bulk concentrations x and y is located on this diagram. A construction of this type is shown in Fig. 5-27, which represents a gas-absorption situation.

The interfacial mole fractions y_i and x_i can be determined by solving Eq. (5-265) simultaneously with the equilibrium relation $y_i^\circ = F(x_i)$ to obtain y_i and x_i. The rate of transfer may then be calculated from Eq. (5-262).

If the equilibrium relation $y_i^\circ = F(x_i)$ is sufficiently simple, e.g., if a plot of y_i° versus x_i is a straight line, not necessarily through the origin, the rate of transfer is proportional to the difference between the bulk concentration in one phase and the concentration (in that same phase) which would be in equilibrium with the bulk concentration in the second phase. One such difference is $y - y^\circ$, and another is $x^\circ - x$. In this case, there is no need to solve for the interfacial compositions, as may be seen from the following derivation.

The rate of mass transfer may be defined by the equation

$$N_A = K_G(y - y^\circ) = k_G(y - y_i) = k_L(x_i - x) = K_L(x^\circ - x) \tag{5-266}$$

where K_G = overall gas-phase mass-transfer coefficient, K_L = overall liquid-phase mass-transfer coefficient, y° = vapor composition in equilibrium with x, and x° = liquid composition in equilibrium with vapor of composition y. This equation can be rearranged to the formula

$$\frac{1}{K_G} = \frac{1}{k_G}\left(\frac{y - y^\circ}{y - y_i}\right) = \frac{1}{k_G} + \frac{1}{k_G}\left(\frac{y_i - y^\circ}{y - y_i}\right) = \frac{1}{k_G} + \frac{1}{k_L}\left(\frac{y_i - y^\circ}{x_i - x}\right) \tag{5-267}$$

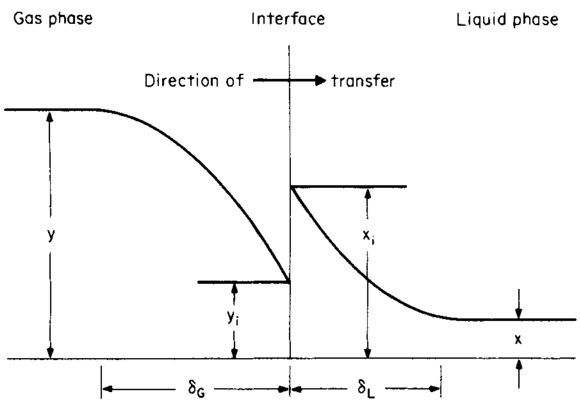

FIG. 5-26 Concentration gradients near a gas-liquid interface.

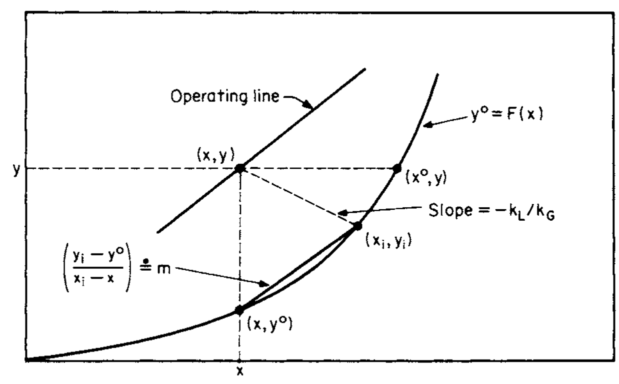

FIG. 5-27 Identification of concentrations at a point in a countercurrent absorption tower.

in view of Eq. (5-265). Comparison of the last term in parentheses with the diagram of Fig. 5-27 shows that it is equal to the slope of the chord connecting the points (x,y°) and (x_i,y_i). If the equilibrium curve is a straight line, then this term is the slope m. Thus

$$1/K_G = (1/k_G + m/k_L) \tag{5-268}$$

When Henry's law is valid ($p_A = Hx_A$ or $p_A = H'C_A$), the slope m can be computed according to the relationship

$$m = H/p_T = H'\overline{\rho}_L/p_T \tag{5-269}$$

where m is defined in terms of mole-fraction driving forces compatible with Eqs. (5-262) through (5-268), i.e., with the definitions of k_L, k_G, and K_G.

If it is desired to calculate the rate of transfer from the overall concentration difference based on bulk-liquid compositions $(x^\circ - x)$, the appropriate overall coefficient K_L is related to the individual coefficients by the equation

$$1/K_L = [1/k_L + 1/(mk_G)] \tag{5-270}$$

Conversion of these equations to a k'_G, k'_L basis can be accomplished readily by direct substitution of Eqs. (5-263) and (5-264).

Occasionally one will find k'_L or K'_L values reported in units (SI) of meters per second. The correct units for these values are kmol/[(s·m^2)(kmol/m^3)], and Eq. (5-264) is the correct equation for converting them to a mole-fraction basis.

When k'_G and K'_G values are reported in units (SI) of kmol/[(s·m^2)(kPa)], one must be careful in converting them to a mole-fraction basis to multiply by the total pressure actually employed in the original experiments and *not* by the total pressure of the system to be designed. This conversion is valid for systems in which Dalton's law of partial pressures ($p = yp_T$) is valid.

Comparison of Eqs. (5-268) and (5-270) shows that for systems in which the equilibrium line is straight, the overall mass transfer coefficients are related to each other by the equation

$$K_L = mK_G \tag{5-271}$$

When the equilibrium curve is not straight, there is no strictly logical basis for the use of an overall transfer coefficient, since the value of m will be a function of position in the apparatus, as can be seen from Fig. 5-27. In such cases the rate of transfer must be calculated by solving for the interfacial compositions as described above.

Experimentally observed rates of mass transfer often are expressed in terms of overall transfer coefficients even when the equilibrium lines are curved. This procedure is empirical, since the theory indicates that in such cases the rates of transfer may not vary in direct proportion to the overall bulk concentration differences $(y - y^\circ)$ and $(x^\circ - x)$ at all concentration levels even though the rates may be proportional to the concentration difference in each phase taken separately, i.e., $(x_i - x)$ and $(y - y_i)$.

In most types of separation equipment such as packed or spray towers, the interfacial area that is effective for mass transfer cannot be accurately determined. For this reason it is customary to report experimentally observed rates of transfer in terms of transfer coefficients based on a unit volume of the apparatus rather than on a unit of interfacial area. Such volumetric coefficients are designated as K_Ga, k_La, etc., where a represents the interfacial area per unit volume of the apparatus. Experimentally observed variations in the values of these volumetric coefficients with variations in flow rates, type of packing, etc., may be due as much to changes in the effective value of a as to changes in k. Calculation of the overall coefficients from the individual volumetric coefficients is made by means of the equations

$$1/K_Ga = (1/k_Ga + m/k_La) \tag{5-272}$$

$$1/K_La = (1/k_La + 1/mk_Ga) \tag{5-273}$$

Because of the wide variation in equilibrium, the variation in the values of m from one system to another can have an important effect on the overall coefficient and on the selection of the type of equipment to use. For example, if m is large, the liquid-phase part of the overall resistance might be extremely large where k_L might be relatively small. This kind of reasoning must be applied with caution, however, since species with different equilibrium characteristics are separated under different operating conditions. Thus, the effect of changes in m on the overall resistance to mass transfer may partly be counterbalanced by changes in the individual specific resistances as the flow rates are changed.

Mass-Transfer Principles: Concentrated Systems When solute concentrations in the gas and/or liquid phases are large, the equations derived above for dilute systems no longer are applicable. The correct equations to use for concentrated systems are as follows:

$$\begin{aligned} N_A &= \hat{k}_G(y - y_i)/y_{BM} = \hat{k}_L(x_i - x)/x_{BM} \\ &= \hat{K}_G(y - y^\circ)/y^\circ_{BM} = \hat{K}_L(x^\circ - x)/x^\circ_{BM} \end{aligned} \tag{5-274}$$

where ($N_B = 0$)

$$y_{BM} = \frac{(1 - y) - (1 - y_i)}{\ln[(1 - y)/(1 - y_i)]} \tag{5-275}$$

$$y^\circ_{BM} = \frac{(1 - y) - (1 - y^\circ)}{\ln[(1 - y)/(1 - y^\circ)]} \tag{5-276}$$

$$x_{BM} = \frac{(1 - x) - (1 - x_i)}{\ln[(1 - x)/(1 - x_i)]} \tag{5-277}$$

$$x^\circ_{BM} = \frac{(1 - x) - (1 - x^\circ)}{\ln[(1 - x)/(1 - x^\circ)]} \tag{5-278}$$

and where $\hat{k}_G$ and $\hat{k}_L$ are the gas-phase and liquid-phase mass-transfer coefficients for concentrated systems and $\hat{K}_G$ and $\hat{K}_L$ are the overall gas-phase and liquid-phase mass-transfer coefficients for concentrated systems. These coefficients are defined later in Eqs. (5-281) to (5-283).

The factors y_{BM} and x_{BM} arise from the fact that, in the diffusion of a solute through a second stationary layer of insoluble fluid, the resistance to diffusion varies in proportion to the concentration of the insoluble stationary fluid, approaching zero as the concentration of the insoluble fluid approaches zero. See Eq. (5-198).

The factors y°_{BM} and x°_{BM} cannot be justified on the basis of mass-transfer theory since they are based on overall resistances. These factors therefore are included in the equations by analogy with the corresponding film equations.

In dilute systems the logarithmic-mean insoluble-gas and nonvolatile-liquid concentrations approach unity, and Eq. (5-274) reduces to the dilute-system formula. For equimolar counter diffusion (e.g., binary distillation), these log-mean factors should be omitted. See Eq. (5-197).

Substitution of Eqs. (5-275) through (5-278) into Eq. (5-274) results in the following simplified formula:

$$\begin{aligned} N_A &= \hat{k}_G \ln[(1 - y_i)/(1 - y)] \\ &= \hat{K}_G \ln[(1 - y^\circ)/(1 - y)] \\ &= \hat{k}_L \ln[(1 - x)/(1 - x_i)] \\ &= \hat{K}_L \ln[(1 - x)/(1 - x^\circ)] \end{aligned} \tag{5-279}$$

Note that the units of $\hat{k}_G$, $\hat{K}_G$, $\hat{k}_L$, and $\hat{K}_L$ are all identical to each other, i.e., kmol/(s·m^2) in SI units.

The equation for computing the interfacial gas and liquid compositions in concentrated systems is

$$\begin{aligned} (y - y_i)/(x_i - x) &= \hat{k}_L y_{BM}/\hat{k}_G x_{BM} \\ &= L_M H_G y_{BM}/G_M H_L x_{BM} = k_L/k_G \end{aligned} \tag{5-280}$$

This equation is identical to the one for dilute systems since $\hat{k}_G = k_G y_{BM}$ and $\hat{k}_L = k_L x_{BM}$. Note, however, that when $\hat{k}_G$ and $\hat{k}_L$ are given, the equation must be solved by trial and error, since x_{BM} contains x_i and y_{BM} contains y_i.

The overall gas-phase and liquid-phase mass-transfer coefficients for concentrated systems are computed according to the following equations:

$$\frac{1}{\hat{K}_G} = \frac{y_{BM}}{y^\circ_{BM}}\frac{1}{\hat{k}_G} + \frac{x_{BM}}{y^\circ_{BM}}\frac{1}{\hat{k}_L}\left(\frac{y_i - y^\circ}{x_i - x}\right) \tag{5-281}$$

$$\frac{1}{\hat{K}_L} = \frac{x_{BM}}{x^\circ_{BM}}\frac{1}{\hat{k}_L} + \frac{y_{BM}}{x^\circ_{BM}}\frac{1}{\hat{k}_G}\left(\frac{x^\circ - x_i}{y - y_i}\right) \tag{5-282}$$

When the equilibrium curve is a straight line, the terms in parentheses can be replaced by the slope m or 1/m as before. In this case the

overall mass-transfer coefficients for concentrated systems are related to each other by the equation

$$\hat{K}_L = m\hat{K}_G(x^\circ_{BM}/y^\circ_{BM}) \tag{5-283}$$

All these equations reduce to their dilute-system equivalents as the inert concentrations approach unity in terms of mole fractions of inert concentrations in the fluids.

HTU (Height Equivalent to One Transfer Unit) Frequently the values of the individual coefficients of mass transfer are so strongly dependent on flow rates that the quantity obtained by dividing each coefficient by the flow rate of the phase to which it applies is more nearly constant than the coefficient itself. The quantity obtained by this procedure is called the height equivalent to one transfer unit, since it expresses in terms of a single length dimension the height of apparatus required to accomplish a separation of standard difficulty.

The following relations between the transfer coefficients and the values of HTU apply:

$$H_G = G_M/k_G a y_{BM} = G_M/\hat{k}_G a \tag{5-284}$$

$$H_{OG} = G_M/K_G a y^\circ_{BM} = G_M/\hat{K}_G a \tag{5-285}$$

$$H_L = L_M/k_L a x_{BM} = L_M/\hat{k}_L a \tag{5-286}$$

$$H_{OL} = L_M/K_L a x^\circ_{BM} = L_M/\hat{K}_L a \tag{5-287}$$

The equations that express the addition of individual resistances in terms of HTUs, applicable to either dilute or concentrated systems, are

$$H_{OG} = \frac{y_{BM}}{y^\circ_{BM}} H_G + \frac{mG_M}{L_M}\frac{x_{BM}}{y^\circ_{BM}} H_L \tag{5-288}$$

$$H_{OL} = \frac{x_{BM}}{x^\circ_{BM}} H_L + \frac{L_M}{mG_M}\frac{y_{BM}}{x^\circ_{BM}} H_G \tag{5-289}$$

These equations are strictly valid only when m, the slope of the equilibrium curve, is constant, as noted previously.

NTU (Number of Transfer Units) The NTU required for a given separation is closely related to the number of theoretical stages or plates required to carry out the same separation in a stagewise or plate-type apparatus. For equimolal counterdiffusion, such as in a binary distillation, the number of overall gas-phase transfer units N_{OG} required for changing the composition of the vapor stream from y_1 to y_2 is

$$N_{OG} = \int_{y_2}^{y_1} \frac{dy}{y - y^\circ} \tag{5-290}$$

When diffusion is in one direction only, as in the absorption of a soluble component from an insoluble gas,

$$N_{OG} = \int_{y_2}^{y_1} \frac{y^\circ_{BM}\,dy}{(1-y)(y-y^\circ)} \tag{5-291}$$

The total height of packing required is then

$$h_T = H_{OG}N_{OG} \tag{5-292}$$

When it is known that H_{OG} varies appreciably within the tower, this term must be placed inside the integral in Eqs. (5-290) and (5-291) for accurate calculations of h_T. For example, the packed-tower design equation in terms of the overall gas-phase mass-transfer coefficient for absorption would be expressed as follows:

$$h_T = \int_{y_2}^{y_1} \left[\frac{G_M}{K_G a y^\circ_{BM}}\right] \frac{y^\circ_{BM}\,dy}{(1-y)(y-y^\circ)} \tag{5-293}$$

where the first term under the integral can be recognized as the HTU term. Convenient solutions of these equations for special cases are discussed later.

Definitions of Mass-Transfer Coefficients $\hat{k}_G$ and $\hat{k}_L$ The mass-transfer coefficient is defined as the ratio of the molal mass flux N_A to the concentration driving force. This leads to many different ways of defining these coefficients. For example, gas-phase mass-transfer rates may be defined as

$$N_A = k_G(y - y_i) = k'_G(p - p_i) = \hat{k}_G(y - y_i)/y_{BM} \tag{5-294}$$

where the units (SI) of k_G are kmol/[(s·m^2)(mole fraction)], the units of k'_G are kmol/[(s·m^2)(kPa)], and the units of $\hat{k}_G$ are kmol/(s·m^2). These coefficients are related to each other as follows:

$$k_G = k_G y_{BM} = k'_G p_T y_{BM} \tag{5-295}$$

where p_T is the total system pressure (it is assumed here that Dalton's law of partial pressures is valid).

In a similar way, liquid-phase mass-transfer rates may be defined by the relations

$$N_A = k_L(x_i - x) = k'_L(c_i - c) = \hat{k}_L(x_i - x)/x_{BM} \tag{5-296}$$

where the units (SI) of k_L are kmol/[(s·m^2)(mole fraction)], the units of k'_L are kmol/[(s·m^2)(kmol/m^3)] or meters per second, and the units of $\hat{k}_L$ are kmol/(s·m^2). These coefficients are related as follows:

$$\hat{k}_L = k_L x_{BM} = k'_L \bar{\rho}_L x_{BM} \tag{5-297}$$

where $\bar{\rho}_L$ is the molar density of the liquid phase in units (SI) of kilomoles per cubic meter. Note that, for dilute solutions where $x_{BM} \doteq 1$, k_L and $\hat{k}_L$ will have identical numerical values. Similarly, for dilute gases $\hat{k}_G \doteq k_G$.

Simplified Mass-Transfer Theories In certain simple situations, the mass-transfer coefficients can be calculated from first principles. The film, penetration, and surface-renewal theories are attempts to extend these theoretical calculations to more complex situations. Although these theories are often not accurate, they are useful to provide a physical picture for variations in the mass-transfer coefficient.

For the special case of steady-state unidirectional diffusion of a component through an inert-gas film in an ideal-gas system, the rate of mass transfer is derived as

$$N_A = \frac{D_{AB}p_T}{RT\,\delta_G}\frac{(y - y_i)}{y_{BM}} = \frac{D_{AB}p_T}{RT\,\delta_G}\ln\frac{1 - y_i}{1 - y} \tag{5-298}$$

where D_{AB} = the diffusion coefficient or "diffusivity," δ_G = the "effective" thickness of a stagnant-gas layer which would offer a resistance to molecular diffusion equal to the experimentally observed resistance, and R = the gas constant. [Nernst, *Z. Phys. Chem.*, **47,** 52 (1904); Whitman, *Chem. Mat. Eng.*, **29,** 149 (1923), and Lewis and Whitman, *Ind. Eng. Chem.*, **16,** 1215 (1924)].

The film thickness δ_G depends primarily on the hydrodynamics of the system and hence on the Reynolds number and the Schmidt number. Thus, various correlations have been developed for different geometries in terms of the following dimensionless variables:

$$N_{Sh} = \hat{k}_G RTd/D_{AB}p_T = f(N_{Re}, N_{Sc}) \tag{5-299}$$

where N_{Sh} is the Sherwood number, N_{Re} (= Gd/μ_G) is the Reynolds number based on the characteristic length d appropriate to the geometry of the particular system; and N_{Sc} (= $\mu_G/\rho_G D_{AB}$) is the Schmidt number.

According to this analysis one can see that for gas-absorption problems, which often exhibit unidirectional diffusion, the most appropriate driving-force expression is of the form $(y - y_i)/y_{BM}$, and the most appropriate mass-transfer coefficient is therefore $\hat{k}_G$. This concept is to be found in all the key equations for the design of mass-transfer equipment.

The Sherwood-number relation for gas-phase mass-transfer coefficients as represented by the film diffusion model in Eq. (5-299) can be rearranged as follows:

$$N_{Sh} = (\hat{k}_G/G_M)N_{Re}N_{Sc} = N_{St}N_{Re}N_{Sc} = f(N_{Re}, N_{Sc}) \tag{5-300}$$

where $N_{St} = \hat{k}_G/G_M = k'_G p_{BM}/G_M$ is known as the Stanton number. This equation can now be stated in the alternative functional forms

$$N_{St} = \hat{k}_G/G_M = g(N_{Re}, N_{Sc}) \tag{5-301}$$

$$j_D = N_{St} \cdot N_{Sc}^{2/3} \tag{5-302}$$

where j is the Chilton-Colburn "j factor" for mass transfer (discussed later).

The important point to note here is that the gas-phase mass-transfer coefficient $\hat{k}_G$ depends principally upon the transport properties of the fluid (N_{Sc}) and the hydrodynamics of the particular system involved (N_{Re}). It also is important to recognize that specific mass-transfer correlations can be derived only in conjunction with the

investigator's particular assumptions concerning the numerical values of the effective interfacial area a of the packing.

The stagnant-film model discussed previously assumes a steady state in which the local flux across each element of area is constant; i.e., there is no accumulation of the diffusing species within the film. Higbie [*Trans. Am. Inst. Chem. Eng.,* **31,** 365 (1935)] pointed out that industrial contactors often operate with repeated brief contacts between phases in which the contact times are too short for the steady state to be achieved. For example, Higbie advanced the theory that in a packed tower the liquid flows across each packing piece in laminar flow and is remixed at the points of discontinuity between the packing elements. Thus, a fresh liquid surface is formed at the top of each piece, and as it moves downward, it absorbs gas at a decreasing rate until it is mixed at the next discontinuity. This is the basis of penetration theory.

If the velocity of the flowing stream is uniform over a very deep region of liquid (total thickness, $\delta_T >> \sqrt{Dt}$), the time-averaged mass-transfer coefficient according to penetration theory is given by

$$k'_L = 2\sqrt{D_L/\pi t} \tag{5-303}$$

where k'_L = liquid-phase mass-transfer coefficient, D_L = liquid-phase diffusion coefficient, and t = contact time.

In practice, the contact time t is not known except in special cases in which the hydrodynamics are clearly defined. This is somewhat similar to the case of the stagnant-film theory in which the unknown quantity is the thickness of the stagnant layer δ (in film theory, the liquid-phase mass-transfer coefficient is given by $k'_L = D_L/\delta$).

The penetration theory predicts that k'_L should vary by the square root of the molecular diffusivity, as compared with film theory, which predicts a first-power dependency on D. Various investigators have reported experimental powers of D ranging from 0.5 to 0.75, and the Chilton-Colburn analogy suggests a ⅔ power.

Penetration theory often is used in analyzing absorption with chemical reaction because it makes no assumption about the depths of penetration of the various reacting species, and it gives a more accurate result when the diffusion coefficients of the reacting species are not equal. When the reaction process is very complex, however, penetration theory is more difficult to use than film theory, and the latter method normally is preferred.

Danckwerts [*Ind. Eng. Chem.,* **42,** 1460 (1951)] proposed an extension of the penetration theory, called the surface renewal theory, which allows for the eddy motion in the liquid to bring masses of fresh liquid continually from the interior to the surface, where they are exposed to the gas for finite lengths of time before being replaced. In his development, Danckwerts assumed that every element of fluid has an equal chance of being replaced regardless of its age. The Danckwerts model gives

$$k'_L = \sqrt{Ds} \tag{5-304}$$

where s = fractional rate of surface renewal.

Note that both the penetration and the surface-renewal theories predict a square-root dependency on D. Also, it should be recognized that values of the surface-renewal rate s generally are not available, which presents the same problems as do δ and t in the film and penetration models.

The predictions of correlations based on the film model often are nearly identical to predictions based on the penetration and surface-renewal models. Thus, in view of its relative simplicity, the film model normally is preferred for purposes of discussion or calculation. It should be noted that none of these theoretical models has proved adequate for making a priori predictions of mass-transfer rates in packed towers, and therefore empirical correlations such as those outlined later in Table 5-24 must be employed.

Mass-Transfer Correlations Because of the tremendous importance of mass transfer in chemical engineering, a very large number of studies have determined mass-transfer coefficients both empirically and theoretically. Some of these studies are summarized in Tables 5-17 to 5-24. Each table is for a specific geometry or type of contactor, starting with flat plates, which have the simplest geometry (Table 5-17); then wetted wall columns (Table 5-18); flow in pipes and ducts (Table 5-19); submerged objects (Table 5-20); drops and bubbles (Table 5-21); agitated systems (Table 5-22); packed beds of particles for adsorption, ion exchange, and chemical reaction (Table 5-23); and finishing with packed bed two-phase contactors for distillation, absorption and other unit operations (Table 5-24). Although extensive, these tables are not meant to be encyclopedic, but a variety of different configurations are shown to provide a flavor of the range of correlations available. These correlations include transfer to or from one fluid and either a second fluid or a solid. Many of the correlations are for k_L and k_G values obtained from dilute systems where $x_{BM} \approx 1.0$ and $y_{BM} \approx 1.0$. The most extensive source for older mass-transfer correlations in a variety of geometries is Skelland (*Diffusional Mass Transfer,* 1974). The extensive review of bubble column systems (see Table 5-21) by Shah et al. [*AIChE J.* **28,** 353 (1982)] includes estimation of bubble size, gas holdup, interfacial area k_La, and liquid dispersion coefficent. For correlations for particle-liquid mass transfer in stirred tanks (part of Table 5-22) see the review by Pangarkar et al. [*Ind. Eng. Chem. Res.* **41,** 4141 (2002)]. For mass transfer in distillation, absorption, and extraction in packed beds (Table 5-24), see also the appropriate sections in this handbook and the review by Wang, Yuan, and Yu [*Ind. Eng. Chem. Res.* **44,** 8715 (2005)]. For simple geometries, one may be able to determine a theoretical (T) form of the mass-transfer correlation. For very complex geometries, only an empirical (E) form can be found. In systems of intermediate complexity, semiempirical (S) correlations where the form is determined from theory and the coefficients from experiment are often useful. Although the major limitations and constraints in use are usually included in the tables, obviously many details cannot be included in this summary form. Readers are strongly encouraged to check the references before using the correlations in important situations. Note that even authoritative sources occasionally have typographical errors in the fairly complex correlation equations. Thus, it is a good idea to check several sources, including the original paper. The references will often include figures comparing the correlations with data. These figures are very useful since they provide a visual picture of the scatter in the data.

Since there are often several correlations that are applicable, how does one choose the correlation to use? First, the engineer must determine which correlations are closest to the current situation. This involves recognizing the similarity of geometries, which is often challenging, and checking that the range of parameters in the correlation is appropriate. For example, the Bravo, Rocha, and Fair correlation for distillation with structured packings with triangular cross-sectional channels (Table 5-24-H) uses the Johnstone and Pigford correlation for rectification in vertical wetted wall columns (Table 5-18-F). Recognizing that this latter correlation pertains to a rather different application and geometry was a nontrivial step in the process of developing a correlation. If several correlations appear to be applicable, check to see if the correlations have been compared to each other and to the data. When a detailed comparison of correlations is not available, the following heuristics may be useful:

1. Mass-transfer coefficients are derived from models. They must be employed in a similar model. For example, if an arithmetic concentration difference was used to determine k, that k should only be used in a mass-transfer expression with an arithmetic concentration difference.
2. Semiempirical correlations are often preferred to purely empirical or purely theoretical correlations. Purely empirical correlations are dangerous to use for extrapolation. Purely theoretical correlations may predict trends accurately, but they can be several orders of magnitude off in the value of k.
3. Correlations with broader data bases are often preferred.
4. The analogy between heat and mass transfer holds over wider ranges than the analogy between mass and momentum transfer. Good heat transfer data (without radiation) can often be used to predict mass-transfer coefficients.
5. More recent data is often preferred to older data, since end effects are better understood, the new correlation often builds on earlier data and analysis, and better measurement techniques are often available.
6. With complicated geometries, the product of the interfacial area per volume and the mass-transfer coefficient is required. Correlations of ka_p or of HTU are more accurate than individual correlations of k and

TABLE 5-18 Mass-Transfer Correlations for Falling Films with a Free Surface in Wetted Wall Columns—Transfer between Gas and Liquid

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
A. Laminar, vertical wetted wall column	$N_{Sh,avg} = \frac{k'_m x}{D} \approx 3.41 \frac{x}{\delta_{\text{film}}}$ (first term of infinite series) $\delta_{\text{film}} = \left(\frac{3\mu Q}{w\rho g}\right)^{1/3}$ = film thickness $N_{Re,\text{film}} = \frac{4Q\rho}{w\mu} < 20$	[T] Low rates M.T. Use with log mean concentration difference. Parabolic velocity distribution in films. w = film width (circumference in column) Derived for flat plates, used for tubes if $r_{\text{tube}}\left(\frac{\rho g}{2\sigma}\right)^{1/2} > 3.0$. σ = surface tension If $N_{Re,\text{film}} > 20$, surface waves and rates increase. An approximate solution D_{apparent} can be used. Ripples are suppressed with a wetting agent good to N_{Re} = 1200.	[138] p. 78 [141] p. 137 [152] p. 50
B. Turbulent, vertical wetted wall column	$N_{Sh,avg} = \frac{k'_m d_t}{D} = 0.023 N_{Re}^{0.83} N_{Sc}^{0.44}$ A coefficient 0.0163 has also been reported using $N_{Re'}$, where $v = v$ of gas relative to liquid film.	[E] Use with log mean concentration difference for correlations in B and D. N_{Re} is for gas. N_{Sc} for vapor in gas. $2000 < N_{Re} \leq 35{,}000$, $0.6 \leq N_{Sc} \leq 2.5$. Use for gases, d_t = tube diameter.	[68] [77] p.181 [138] p. 211 [141] p. 265 [149] p. 212 [152] p. 71
Better fit	$N_{Sh,avg} = 0.0318 N_{Re}^{0.790} N_{Sc}^{0.5}$	[S] Reevaluated data	[58]
C. Turbulent, very short column	$N_{Sh} = 0.00283 N_{Re,g} N_{Sc,g}^{0.5} N_{Re,liq}^{0.08}$ $N_{Sh} = k_g(d_{\text{tube}} - 2\delta)/D$ $N_{Re,g} = \rho_g u_g (d_{\text{tube}} - 2\delta)/\mu_g$ $N_{Re,liq} = \rho_{liq} Q_{liq}/[\pi\mu(d_{\text{tube}} - 2\delta)]$	[E] Evaporation data $N_{Sh,g}$ = 11 to 65, $N_{Re,g}$ = 2400 to 9100 $N_{Re,liq}$ = 110 to 480, $N_{Sc,g}$ = 0.62 to 1.93 δ = film thickness	[56]
D. Turbulent, vertical wetted wall column with ripples	$N_{Sh,avg} = \frac{k'_m d_t}{D} = 0.00814 N_{Re}^{0.83} N_{Sc}^{0.44} \left(\frac{4Q\rho}{w\mu}\right)^{0.15}$ $30 \leq \left(\frac{4Q\rho}{w\mu}\right) < 1200$ $N_{Sh,avg} = \frac{k'_m d_t}{D} = 0.023 N_{Re}^{0.8} N_{Sc}^{1/3}$	[E] For gas systems with rippling. Fits 5-18-*B* for $\left(\frac{4Q\rho}{w\mu}\right) = 1000$ [E] "Rounded" approximation to include ripples. Includes solid-liquid mass-transfer data to find ⅓ coefficient on N_{Sc}. May use $N_{Re}^{0.83}$. Use for liquids. See also Table 5-19.	[85] [138] p. 213
E. Turbulent, with ripples	$N_{Sh} = \left(\frac{2}{\pi}\right)^{0.5} N_{Re,\dot{\varepsilon}}^{0.5} N_{Sc}^{0.5}$ $N_{Re,\dot{\varepsilon}} = \dot{\varepsilon} L^2/\nu$	[E] $\dot{\varepsilon}$ = dilation rate of surface = $\frac{\partial v_x^c}{\partial x} + \frac{\partial v_y^s}{\partial y}$	[150]
F. Rectification in vertical wetted wall column with turbulent vapor flow, Johnstone and Pigford correlation	$N_{Sh,avg} = \frac{k'_G d_{\text{col}} p_{BM}}{D_v p} = 0.0328 (N'_{Re})^{0.77} N_{Sc}^{0.33}$ $3000 < N'_{Re} < 40{,}000$, $0.5 < N_{Sc} < 3$ $N'_{Re} = \frac{d_{col} v_{rel} \rho_v}{\mu_v}$, v_{rel} = gas velocity relative to liquid film = $\frac{3}{2} u_{avg}$ in film	[E] Use logarithmic mean driving force at two ends of column. Based on four systems with gas-side resistance only. p_{BM} = logarithmic mean partial pressure of nondiffusing species B in binary mixture. p = total pressure Modified form is used for structured packings (See Table 5-24-H).	[84] [138] p. 214 [156]

*See the beginning of the "Mass Transfer" subsection for references.

a_p since the measurements are simpler to determine the product ka_p or HTU.

7. Finally, if a mass-transfer coefficient looks too good to be true, it probably is incorrect.

To determine the mass-transfer rate, one needs the interfacial area in addition to the mass-transfer coefficient. For the simpler geometries, determining the interfacial area is straightforward. For packed beds of particles *a,* the interfacial area per volume can be estimated as shown in Table 5-23-A. For packed beds in distillation, absorption, and so on in Table 5-24, the interfacial area per volume is included with the mass-transfer coefficient in the correlations for HTU. For agitated liquid-liquid systems, the interfacial area can be estimated from the dispersed phase holdup and mean drop size correlations. Godfrey, Obi, and Reeve [*Chem. Engr. Prog.* **85,** 61 (Dec. 1989)] summarize these correlations. For many systems, $\bar{d}_{\text{drop}}/d_{\text{imp}}$ = (const)$N_{\text{We}}^{-0.6}$ where $N_{\text{We}} = \rho_c N^2 d_{\text{imp}}^3/\sigma$. Piché, Grandjean, and Larachi [*Ind. Eng. Chem. Res.* **41**, 4911 (2002)] developed two correlations for reconciling the gas-liquid mass-transfer coefficient and interfacial area in randomly packed towers. The correlation for the interfacial area was a function of five dimensionless groups, and yielded a relative error of 22.5 percent for 325 data points. That equation, when combined with a correlation for N_{Sh} as a function of four dimensionless groups, achieved a relative error of 24.4 percent, for 3455 data points for the product $k'_G a$.

TABLE 5-19 Mass-Transfer Correlations for Flow in Pipes and Ducts—Transfer Is from Wall to Fluid

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
A. Tubes, laminar, fully developed parabolic velocity profile, developing concentration profile, constant wall concentration	$N_{Sh} = \frac{k'd_t}{D} = 3.66 + \frac{0.0668(d_t/x)N_{Re}N_{Sc}}{1 + 0.04[(d_t/x)N_{Re}N_{Sc}]^{2/3}}$	[T] Use log mean concentration difference. For $\frac{x/d_t}{N_{Re}N_{Sc}} < 0.10$, $N_{Re} < 2100$. x = distance from tube entrance. Good agreement with experiment at values $10^4 > \frac{\pi}{4}\frac{d_t}{x}N_{Re}N_{Sc} > 10$	[77] p. 176 [87] p. 525 [141] p. 159
Fully developed concentration profile	$N_{Sh} = \frac{k'd_t}{D} = 3.66$	[T] $\frac{x/d_t}{N_{Re}N_{Sc}} > 0.1$	[141] p. 165
B. V. Tubes, turbulent, smooth tubes, Constant surface concentration, Von Karman analogy	$N_{Sh} = \dfrac{(f/2)N_{Re}N_{Sc}}{1+5\sqrt{f/2}\left\{(N_{Sc}-1)+\ln\left[1+\dfrac{5}{6}(N_{Sc}-1)\right]\right\}}$ $\dfrac{f}{2} = 0.04N_{Re}^{-0.25}$	[T] Use arithmetic concentration difference. $N_{Sh} = k'd_t/D$. Improvement over Prandtl, $N_{Sc} < 25$.	[77] p. 173 [141] p. 243 [149] p. 250 [154]
W. Tubes, turbulent, smooth tubes, constant surface concentration	For $0.5 < N_{Sc} < 10$: $N_{Sh,avg} = 0.0097N_{Re}^{9/10}N_{Sc}^{1/2} \times (1.10 + 0.44N_{Sc}^{-1/3} - 0.70N_{Sc}^{-1/6})$ For $10 < N_{Sc} < 1000$: $N_{Sh,avg}$ $= \dfrac{0.0097N_{Re}^{9/10}N_{Sc}^{1/2}(1.10+0.44N_{Sc}^{-1/3}-0.70N_{Sc}^{-1/6})}{1+0.064N_{Sc}^{1/2}(1.10+0.44N_{Sc}^{-1/3}-0.70N_{Sc}^{-1/6})}$ For $N_{Sc} > 1000$: $N_{Sh,avg} = 0.0102N_{Re}^{9/10}N_{Sc}^{1/3}$	[S] Use arithmetic concentration difference. Based on partial fluid renewal and an infrequently replenished thin fluid layer for high N_{Sc}. Good fit to available data. $N_{Re} = \dfrac{u_{\text{bulk}}\,d_t}{\nu}$ $N_{Sh,avg} = \dfrac{k'_{avg}\,d_t}{D}$	[77] p. 179 [117]
X. Turbulent flow, tubes	$N_{St} = \dfrac{N_{Sh}}{N_{Pe}} = \dfrac{N_{Sh}}{N_{Re}N_{Sc}} = 0.0149N_{Re}^{-0.12}N_{Sc}^{-2/3}$	[E] Smooth pipe data. Data fits within 4% except at $N_{Sc} > 20{,}000$, where experimental data is underpredicted. $N_{Sc} > 100$, $10^5 > N_{Re} > 2100$	[107]
Y. Turbulent flow, noncircular ducts	Use correlations with $d_{eq} = \dfrac{4 \text{ cross-sectional area}}{\text{wetted perimeter}}$	Can be suspect for systems with sharp corners. Parallel plates: $d_{eq} = 4\,\dfrac{2hw}{2w+2h}$	[141] p. 289
Z. Decaying swirling flow in pipe	$N_{Sh,avg} = 0.3508N_{Sc}^{1/3}N_{\text{Re}}^{0.759}(x/d)^{-0.400} \times (1+\tan\theta)^{0.271}$ N_{Re} = 1730 to 8650, N_{Sc} = 1692	[E,S] x = axial distance, d = diameter, θ = vane angle (15° to 60°) Regression coefficient = 0.9793. Swirling increases mass transfer.	[161]

*See the beginning of the "Mass Transfer" subsection for references.

Effects of Total Pressure on $\hat{k}_G$ and $\hat{k}_L$ The influence of total system pressure on the rate of mass transfer from a gas to a liquid or to a solid has been shown to be the same as would be predicted from stagnant-film theory as defined in Eq. (5-298), where

$$\hat{k}_G = D_{AB}p_T/RT\,\delta_G \tag{5-305}$$

Since the quantity $D_{AB}p_T$ is known to be relatively independent of the pressure, it follows that the rate coefficients $\hat{k}_G$, $k_G y_{BM}$, and $k'_G p_T y_{BM}$ ($= k'_G p_{BM}$) do not depend on the total pressure of the system, subject to the limitations discussed later.

Investigators of tower packings normally report $k'_G a$ values measured at very low inlet-gas concentrations, so that $y_{BM} = 1$, and at total pressures close to 100 kPa (1 atm). Thus, the correct rate coefficient for use in packed-tower designs involving the use of the driving force $(y - y_i)/y_{BM}$ is obtained by multiplying the reported $k'_G a$ values by the value of p_T employed in the actual test unit (e.g., 100 kPa) and *not* the total pressure of the system to be designed.

From another point of view one can correct the reported values of $k'_G a$ in kmol/[(s·m³)(kPa)], valid for a pressure of 101.3 kPa (1 atm), to some other pressure by dividing the quoted values of $k'_G a$ by the design pressure and multiplying by 101.3 kPa, i.e., ($k'_G a$ at design pressure p_T) = ($k'_G a$ at 1 atm) × 101.3/p_T.

One way to avoid a lot of confusion on this point is to convert the experimentally measured $k'_G a$ values to values of $\hat{k}_G a$ straightaway, before beginning the design calculations. A design based on the rate coefficient $\hat{k}_G a$ and the driving force $(y - y_i)/y_{BM}$ will be independent of the total system pressure with the following limitations: caution should be employed in assuming that $\hat{k}_G a$ is independent of total pressure for systems having significant vapor-phase nonidealities, for systems that operate in the vicinity of the critical point, or for total pressures higher than about 3040 to 4050 kPa (30 to 40 atm).

Experimental confirmations of the relative independence of $\hat{k}_G$ with respect to total pressure have been widely reported. Deviations do occur at extreme conditions. For example, Bretsznajder (*Prediction of Transport and Other Physical Properties of Fluids,* Pergamon Press, Oxford, 1971, p. 343) discusses the effects of pressure on the $D_{AB}p_T$ product and presents experimental data on the self-diffusion of CO_2 which show that the *D-p* product begins to decrease at a pressure of approximately 8100 kPa (80 atm). For reduced temperatures higher than about 1.5, the deviations are relatively modest for pressures up to the critical pressure. However, deviations are large near the critical point (see also p. 5-52). The effect of pressure on the gas-phase viscosity also is negligible for pressures below about 5060 kPa (50 atm).

For the liquid-phase mass-transfer coefficient $\hat{k}_L$, the effects of total system pressure can be ignored for all practical purposes. Thus, when using $\hat{k}_G$ and $\hat{k}_L$ for the design of gas absorbers or strippers, the primary pressure effects to consider will be those which affect the equilibrium curves and the values of m. If the pressure changes affect the hydrodynamics, then $\hat{k}_G$, $\hat{k}_L$, and a can all change significantly.

Effects of Temperature on $\hat{k}_G$ and $\hat{k}_L$ The Stanton-number relationship for gas-phase mass transfer in packed beds, Eq. (5-301), indicates that for a given system geometry the rate coefficient $\hat{k}_G$ depends only on the Reynolds number and the Schmidt number. Since the Schmidt number for a gas is approximately independent of temperature, the principal effect of temperature upon $\hat{k}_G$ arises from changes in the gas viscosity with changes in temperature. For normally encountered temperature ranges, these effects will be small owing to the fractional powers involved in Reynolds-number terms (see Tables 5-17 to 5-24). It thus can be concluded that for all

A. Single sphere	$N_{Sh} = \dfrac{k'_G p_{BLM} RT d_s}{PD} = \dfrac{2r}{r - r_s}$ r/r_s: 2, 5, 10, 50, ∞ (asymptotic limit) N_{Sh}: 4.0, 2.5, 2.22, 2.04, 2.0	[T] Use with log mean concentration difference. r = distance from sphere, r_s, d_s = radius and diameter of sphere. No convection.	[141] p. 18
B. Single sphere, creeping flow with forced convection	$N_{Sh} = \dfrac{k'd}{D} = [4.0 + 1.21(N_{Re}N_{Sc})^{2/3}]^{1/2}$	[T] Use with log mean concentration difference. Average over sphere. Numerical calculations. $(N_{Re}N_{Sc}) < 10{,}000$ $N_{Re} < 1.0$. Constant sphere diameter. Low mass-transfer rates.	[46][88] p. 114 [105] [138] p. 214
	$N_{Sh} = \dfrac{k'd}{D} = a(N_{Re}N_{Sc})^{1/3}$	[T] Fit to above ignoring molecular diffusion.	[101] p. 80
	$a = 1.00 \pm 0.01$	$1000 < (N_{Re}N_{Sc}) < 10{,}000$.	[138] p. 215
C. Single spheres, molecular diffusion, and forced convection, low flow rates	$N_{Sh} = 2.0 + AN_{Re}^{1/2}N_{Sc}^{1/3}$ $A = 0.5$ to 0.62	[E] Use with log mean concentration difference. Average over sphere. Frössling Eq. ($A = 0.552$), $2 \le N_{Re} \le 800$, $0.6 \le N_{sc} \le 2.7$. N_{Sh} lower than experimental at high N_{Re}.	[39] [77], p. 194 [88] p. 114 [141] p. 276
	$A = 0.60.$	[E] Ranz and Marshall $2 \le N_{Re} \le 200$, $0.6 \le N_{sc} \le 2.5$. Modifications recommended [110] See also Table 5-23-O.	[39] p. 409, 647 [121] [110] [138] p. 217 [141] p. 276
	$A = 0.95.$	[E] Liquids $2 \le N_{Re} \le 2{,}000$. Graph in Ref. 138, p. 217–218.	[65][66] p. 482 [138] p. 217
	$A = 0.95.$	[E] $100 \le N_{Re} \le 700$; $1{,}200 \le N_{Sc} \le 1525$.	[126][141] p. 276
	$A = 0.544.$	[E] Use with arithmetic concentration difference. $N_{Sc} = 1$; $50 \le N_{Re} \le 350$.	[81][141] p. 276
D. Same as 5-20-C	$N_{Sh} = \dfrac{k'd_s}{D} = 2.0 + 0.575N_{Re}^{1/2}N_{Sc}^{0.35}$	[E] Use with log mean concentration difference. $N_{Sc} \le 1$, $N_{Re} < 1$.	[70][141] p. 276
E. Same as 5-20-C	$N_{Sh} = \dfrac{k'd_s}{D} = 2.0 + 0.552N_{Re}^{0.53}N_{Sc}^{1/3}$	[E] Use with log mean concentration difference. $1.0 < N_{Re} \le 48{,}000$ Gases: $0.6 \le N_{Sc} \le 2.7$.	[66] p. 482
F. Single spheres, forced concentration, any flow rate	$N_{Sh} = \dfrac{k'_L d_s}{D} = 2.0 + 0.59\left[\dfrac{E^{1/3}d_p^{4/3}\rho}{\mu}\right]^{0.57} N_{Sc}^{1/3}$ Energy dissipation rate per unit mass of fluid (ranges $570 < N_{Sc} < 1420$): $E = \left(\dfrac{C_{Dr}}{2}\right)\left(\dfrac{v_r^3}{d_p}\right)\dfrac{\text{m}^2}{\text{s}^3}$	[S] Correlates large amount of data and compares to published data. v_r = relative velocity between fluid and sphere, m/s. C_{Dr} = drag coefficient for single particle fixed in fluid at velocity v_r. See 5-23-F for calculation details and applications. $2 < \left(\dfrac{E^{1/3}d_p^{4/3}\rho}{\mu}\right) < 63{,}000$	[108]
G. Single spheres, forced convection, high flow rates, ignoring molecular diffusion	$N_{Sh} = \dfrac{k'd_s}{D} = 0.347N_{Re}^{0.62}N_{Sc}^{1/3}$	[E] Use with arithmetic concentration difference. Liquids, $2000 < N_{Re} < 17{,}000$. High N_{Sc}, graph in Ref. 138, p. 217–218.	[66] p. 482 [147] [138] p. 217
	$N_{Sh} = \dfrac{k'd_s}{D} = 0.33N_{Re}^{0.6}N_{Sc}^{1/3}$	[E] $1500 \le N_{Re} \le 12{,}000$.	[141] p. 276
	$N_{Sh} = \dfrac{k'd_s}{D} = 0.43N_{Re}^{0.56}N_{Sc}^{1/3}$	[E] $200 \le N_{Re} \le 4 \times 10^4$, "air" $\le N_{Sc} \le$ "water."	[141] p. 276
	$N_{Sh} = \dfrac{k'd_s}{D} = 0.692N_{Re}^{0.514}N_{Sc}^{1/3}$	[E] $500 \le N_{Re} \le 5000$.	[112] [141] p. 276
H. Single sphere immersed in bed of smaller particles. For gases.	$N_{Sh,avg} = \dfrac{kd_1}{D'} = \varepsilon\left[4 + \dfrac{4}{5}N_{Pe'}^{2/3} + \dfrac{4}{\pi}N_{Pe'}\right]\left(1 + \dfrac{1}{9}N_{Pe'}\right)^{1/2}$ Limit $N_{Pe'} \to 0, N_{Sh,avg} = 2\varepsilon$	[T] Compared to experiment. $N_{Pe'} = \dfrac{u_o d_1}{D'}$, $D' = D/\tau$, D = molecular diffusivity, d_1 = diameter large particle, τ = tortuosity. Arithmetic conc. difference fluid flow in inert bed follows Darcy's law.	[71]
I. Single cylinders, perpendicular flow	$N_{Sh} = \dfrac{k'd_s}{D} = AN_{Re}^{1/2}N_{Sc}^{1/3}$, $A = 0.82$	[E] $100 < N_{Re} \le 3500$, $N_{Sc} = 1560$.	[141] p. 276
	$A = 0.74$	[E] $120 \le N_{Re} \le 6000$, $N_{Sc} = 2.44$.	[141] p. 276
	$A = 0.582$	[E] $300 \le N_{Re} \le 7600$, $N_{Sc} = 1200$.	[142]
	$j_D = 0.600(N_{Re})^{-0.487}$	[E] Use with arithmetic concentration difference.	[141] p. 276
	$N_{Sh} = \dfrac{k'd_{cyl}}{D}$	$50 \le N_{Re} \le 50{,}000$; gases, $0.6 \le N_{Sc} \le 2.6$; liquids; $1000 \le N_{Sc} \le 3000$. Data scatter $\pm$ 30%.	[66] p. 486

TABLE 5-20 Mass-Transfer Correlations for Flow Past Submerged Objects (*Concluded*)

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
J. Rotating cylinder in an infinite liquid, no forced flow	$j_D' = \frac{k'}{v} N_{Sc}^{0.644} = 0.0791 N_{Re}^{-0.30}$ Results presented graphically to $N_{Re} = 241{,}000$. $N_{Re} = \frac{v d_{cyl} \mu}{\rho}$ where $v = \frac{\omega d_{cyl}}{2}$ = peripheral velocity	[E] Used with arithmetic concentration difference. Useful geometry in electrochemical studies. $112 < N_{Re} \leq 100{,}000$. $835 < N_{Sc} < 11490$ k' = mass-transfer coefficient, cm/s; ω = rotational speed, radian/s.	[60] [138] p. 238
K. Stationary or rotating cylinder for air	Stationary: $N_{Sh,avg} = A N_{Re}^c S_c^{1/3}$ $2.0 \times 10^4 \leq N_{Re} \leq 2.5 \times 10^5$; $d/H = 0.3$, Tu = 0.6% $A = 0.0539$, $c = 0.771$ [114] A and c depend on geometry [37] Rotating in still air: $N_{Sh,avg} = 0.169 N_{Re,\omega}^{2/3}$ $1.0E4 \leq N_{Re,\omega} \leq 1.0E5$; $N_{Sc} \approx 2.0$; $N_{Gr} \approx 2.0 \times 10^6$	[E] Reasonable agreement with data of other investigators. d = diameter of cylinder, H = height of wind tunnel, Tu of = turbulence level, N_{Re}w = rotational Reynold's number = $u_\omega d\rho/\mu$, u_ω = cylinder surface velocity. Also correlations for two-dimensional slot jet flow [114]. For references to other correlations see [37].	[37] [114]
L. Oblate spheroid, forced convection	$j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}} = 0.74 N_{Re}^{-0.5}$ $N_{Re} = \frac{d_{ch} v \rho}{\mu}$, $d_{ch} = \frac{\text{total surface area}}{\text{perimeter normal to flow}}$ e.g., for cube with side length a, $d_{ch} = 1.27a$. $N_{Sh} = \frac{k' d_{ch}}{D}$	[E] Used with arithmetic concentration difference. $120 \leq N_{Re} \leq 6000$; standard deviation 2.1%. Eccentricities between 1:1 (spheres) and 3:1. Oblate spheroid is often approximated by drops.	[141] p. 284 [142]
M. Other objects, including prisms, cubes, hemispheres, spheres, and cylinders; forced convection	$j_D = 0.692 N_{Re,p}^{-0.486}$, $N_{Re,p} = \frac{v d_{ch} \rho}{\mu}$ Terms same as in 5-20-J.	[E] Used with arithmetic concentration difference. Agrees with cylinder and oblate spheroid results, ±15%. Assumes molecular diffusion and natural convection are negligible. $500 \leq N_{Re,p} \leq 5000$. Turbulent.	[88] p. 115 [141] p. 285 [111] [112]
N. Other objects, molecular diffusion limits	$N_{Sh} = \frac{k' d_{ch}}{D} = A$	[T] Use with arithmetic concentration difference. Hard to reach limits in experiments. Spheres and cubes $A = 2$, tetrahedrons $A = 2\sqrt{6}$ octahedrons $2\sqrt{2}$.	[88] p. 114
O. Shell side of microporous hollow fiber module for solvent extraction	$N_{Sh} = \beta[d_h(1-\varphi)/L] N_{Re}^{0.6} N_{Sc}^{0.33}$ $N_{Sh} = \frac{\overline{K} d_h}{D}$ $N_{Re} = \frac{d_h v \rho}{\mu}$, $\overline{K}$ = overall mass-transfer coefficient $\beta = 5.8$ for hydrophobic membrane. $\beta = 6.1$ for hydrophilic membrane.	[E] Use with logarithmic mean concentration difference. d_h = hydraulic diameter $= \frac{4 \times \text{cross-sectional area of flow}}{\text{wetted perimeter}}$ φ = packing fraction of shell side. L = module length. Based on area of contact according to inside or outside diameter of tubes depending on location of interface between aqueous and organic phases. Can also be applied to gas-liquid systems with liquid on shell side.	[118]

See Table 5-23 for flow in packed beds.
*See the beginning of the "Mass Transfer" subsection for references.

TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns

Conditions	Correlations	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
A. Single liquid drop in immiscible liquid, drop formation, discontinuous (drop) phase coefficient	$\hat{k}_{df} = A\left(\frac{\rho_d}{M_d}\right)_{av}\left(\frac{D_d}{\pi t_f}\right)^{1/2}$ $A = \frac{24}{7}$ (penetration theory) $A = 1.31$ (semiempirical value) $A = \left[\frac{24}{7}(0.8624)\right]$ (extension by fresh surface elements)	[T,S] Use arithmetic mole fraction difference. Fits some, but not all, data. Low mass transfer rate. M_d = mean molecular weight of dispersed phase; t_f = formation time of drop. $k_{L,d}$ = mean dispersed liquid phase M.T. coefficient kmole/[s·m^2 (mole fraction)].	[141] p. 399
B. Same as 5-21-A	$\hat{k}_{df} = 0.0432 \times \frac{d_p}{t_f}\left(\frac{\rho_d}{M_d}\right)_{av}\left(\frac{u_o}{d_p g}\right)^{0.089}\left(\frac{d_p^2}{t_f D_d}\right)^{-0.334}\left(\frac{\mu_d}{\sqrt{\rho_d d_p \sigma g_c}}\right)^{-0.601}$	[E] Use arithmetic mole fraction difference. Based on 23 data points for 3 systems. Average absolute deviation 26%. Use with surface area of drop after detachment occurs. u_o = velocity through nozzle; σ = interfacial tension.	[141] p. 401 [144] p. 434
C. Single liquid drop in immiscible liquid, drop formation, continuous phase coefficient	$\hat{k}_{cf} = 4.6\left(\frac{\rho_c}{M_c}\right)_{av}\sqrt{\frac{D_c}{\pi t_f}}$	[T] Use arithmetic mole fraction difference. Based on rate of bubble growth away from fixed orifice. Approximately three times too high compared to experiments.	[141] p. 402
D. Same as 5-21-C	$k_{L,c} = 0.386 \times\left(\frac{\rho_c}{M_c}\right)_{av}\left(\frac{D_c}{t_f}\right)^{0.5}\left(\frac{\rho_c\sigma g_c}{\Delta\rho g t_f\mu_c}\right)^{0.407}\left(\frac{g t_f^2}{d_p}\right)^{0.148}$	[E] Average absolute deviation 11% for 20 data points for 3 systems.	[141] p. 402 [144] p. 434
E. Single liquid drop in immiscible liquid, free rise or fall, discontinuous phase coefficient, stagnant drops	$k_{L,d,m} = \frac{-d_p}{6t}\left(\frac{\rho_d}{M_d}\right)_{av}\ln\left\{\frac{6}{\pi^2}\sum_{j=1}^{\infty}\frac{1}{j^2}\exp\left[\left(\frac{-D_d j^2\pi^2 t}{(d_p/2)^2}\right)\right]\right\}$	[T] Use with log mean mole fraction differences based on ends of column. t = rise time. No continuous phase resistance. Stagnant drops are likely if drop is very viscous, quite small, or is coated with surface active agent. $k_{L,d,m}$ = mean dispersed liquid M.T. coefficient.	[141] p. 404 [144] p. 435
F. Same as 5-21-E	$\hat{k}_{L,d,m} = \frac{-d_p}{6t}\left(\frac{\rho_d}{M_d}\right)_{av}\ln\left[1-\frac{\pi D_d^{1/2}t^{1/2}}{d_p/2}\right]$	[S] See 5-21-E. Approximation for fractional extractions less than 50%.	[141] p. 404 [144] p. 435
G. Same as 5-21-E, continuous phase coefficient, stagnant drops, spherical	$N_{Sh} = \frac{k_{L,c,m}d_c}{D_c} = 0.74\left(\frac{\rho_c}{M_c}\right)_{av}N_{Re}^{1/2}(N_{Sc})^{1/3}$	[E] $N_{Re} = \frac{v_s d_p\rho_c}{\mu_c}$, v_s = slip velocity between drop and continuous phase.	[141] p. 407 [142][144] p. 436
H. Single bubble or drop with surfactant. Stokes flow.	$N_{Sh} = 2.0 + \alpha N_{Pe}^{\beta}$, $N_{Sh} = 2rk/D$ $\alpha = \frac{5.49}{A+6.10} + \frac{A}{A+28.64}$ $\beta = \frac{0.35A+17.21}{A+34.14}$ $2r = 2$ to $50\ \mu m$, $A = 2.8E4$ to $7.0E5$ $0.0026 < N_{Pe,s} < 340$, $2.1 < N_{Ma} < 1.3E6$ $N_{Pe} = 1.0$ to 2.5×10^4, $N_{Re} = 2.2\times10^{-6}$ to 0.034	[T] A = surface retardation parameter $A = B\Gamma_o r/\mu D_s = N_{Ma}N_{Pe,s}$ $N_{Ma} = B\Gamma_o/\mu u$ = Marangoni no. Γ = surfactant surface conc. $N_{Pe,s}$ = surface Peclet number = ur/D_s D_s = surface diffusivity N_{Pe} = bulk Peclet number For $A >> 1$ acts like rigid sphere: $\beta \to 0.35$, $\alpha \to 1/2864 = 0.035$	[120]
I. 5-21-E, oblate spheroid	$N_{Sh} = \frac{k_{L,c,m}d_3}{D_c} = 0.74\left(\frac{\rho_c}{M_c}\right)_{av}(N_{Re,3})^{1/2}(N_{Sc,c})^{1/3}$ $N_{Re,3} = \frac{v_s d_3\rho_c}{\mu_c}$	[E] Used with log mean mole fraction. Differences based on ends of extraction column; 100 measured values ±2% deviation. Based on area oblate spheroid. v_s = slip velocity, $d_3 = \frac{\text{total drop surface area}}{\text{perimeter normal to flow}}$	[141] p. 285, 406, 407
J. Single liquid drop in immiscible liquid, Free rise or fall, discontinuous phase coefficient, circulating drops	$k_{dr,circ} = -\frac{d_p}{6\theta}\ln\left[\frac{3}{8}\sum_{j=1}^{\infty}B_j^2\exp\left(-\frac{\lambda_j 64D_d\theta}{d_p^2}\right)\right]$ (Eigenvalues for Circulating Drop: see below)	[T] Use with arithmetic concentration difference. θ = drop residence time. A more complete listing of eigenvalues is given by Refs. 62 and 76. $k'_{L,d,circ}$ is m/s.	[62][76][141] p. 405 [152] p. 523

Eigenvalues for Circulating Drop

$k_d d_p/D_d$	λ_1	λ_2	λ_3	B_1	B_2	B_3
3.20	0.262	0.424		1.49	0.107

∞	1.656	9.08	22.2	1.29	0.596	0.386

TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns (*Continued*)

Conditions	Correlations	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
K. Same as 5-21-J	$\hat{k}_{L,d,\text{circ}} = -\dfrac{d_p}{6\theta}\left(\dfrac{\rho_d}{M_d}\right)_{av} \ln\left[1 - \dfrac{R^{1/2}\pi D_d^{1/2}\theta^{1/2}}{d_p/2}\right]$	[E] Used with mole fractions for extraction less than 50%, $R \approx 2.25$.	[141] p. 405
L. Same as 5-21-J	$N_{Sh} = \dfrac{\hat{k}_{L,d,\text{circ}} d_p}{D_d}$ $= 31.4\left(\dfrac{\rho_d}{M_f}\right)_{av}\left(\dfrac{4D_d t}{d_p^2}\right)^{-0.34} N_{Sc,d}^{-0.125}\left(\dfrac{d_p v_s^2 \rho_c}{\sigma g_c}\right)^{-0.37}$	[E] Used with log mean mole fraction difference. d_p = diameter of sphere with same volume as drop. $856 \le N_{Sc} \le 79{,}800$, $2.34 \le \sigma \le 4.8$ dynes/cm.	[144] p. 435 [145]
M. Liquid drop in immiscible liquid, free rise or fall, continuous phase coefficient, circulating single drops	$N_{Sh,c} = \dfrac{k'_{L,c} d_p}{D_d}$ $= \left[2 + 0.463 N_{Re,\text{drop}}^{0.484} N_{Sc,c}^{0.339}\left(\dfrac{d_p g^{1/3}}{D_c^{2/3}}\right)^{0.072}\right] F$ $F = 0.281 + 1.615K + 3.73K^2 - 1.874K$ $K = N_{Re,\text{drop}}^{1/8}\left(\dfrac{\mu_c}{\mu_d}\right)^{1/4}\left(\dfrac{\mu_c v_s}{\sigma g_c}\right)^{1/6}$	[E] Used as an arithmetic concentration difference. $N_{Re,\text{drop}} = \dfrac{d_p v_s \rho_c}{\mu_c}$ Solid sphere form with correction factor F.	[82]
N. Same as 5-21-M, circulating, single drop	$N_{Sh} = \dfrac{k_{L,c} d_p}{D_c} = 0.6\left(\dfrac{\rho_c}{M_c}\right)_{av} N_{Re,\text{drop}}^{1/2} N_{Sc,c}^{1/2}$	[E] Used as an arithmetic concentration difference. Low σ.	[141] p. 407
O. Same as 5-21-M, circulating swarm of drops	$k_{L,c} = 0.725\left(\dfrac{\rho_c}{M_c}\right)_{av} N_{Re,\text{drop}}^{-0.43} N_{Sc,c}^{-0.58} v_s (1 - \phi_d)$	[E] Used as an arithmetic concentration difference. Low σ, disperse-phase holdup of drop swarm. ϕ_d = volume fraction dispersed phase.	[141] p. 407 [144] p. 436
P. Liquid drops in immiscible liquid, free rise or fall, discontinuous phase coefficient, oscillating drops	$N_{Sh} = \dfrac{k_{L,d,\text{osc}} d_p}{D_d}$ $= 0.32\left(\dfrac{\rho_d}{M_d}\right)_{av}\left(\dfrac{4D_d t}{d_p^2}\right)^{-0.14} N_{Re,\text{drop}}^{0.68}\left(\dfrac{\sigma^3 g_c^3 \rho_c^2}{g\mu_c^4 \Delta\rho}\right)^{0.10}$	[E] Used with a log mean mole fraction difference. Based on ends of extraction column. $N_{Re,\text{drop}} = \dfrac{d_p v_s \rho_c}{\mu_c}$, $411 \le N_{Re} \le 3114$ d_p = diameter of sphere with volume of drop. Average absolute deviation from data, 10.5%. Low interfacial tension (3.5–5.8 dyn), $\mu_c < 1.35$ centipoise.	[141] p. 406 [144] p. 435 [145]
Q. Same as 5-21-P	$k_{L,d,\text{osc}} = \dfrac{0.00375 v_s}{1 + \mu_d/\mu_c}$	[T] Use with log mean concentration difference. Based on end of extraction column. No continuous phase resistance. $k_{L,d,\text{osc}}$ in cm/s, v_s = drop velocity relative to continuous phase.	[138] p. 228 [141] p. 405
R. Single liquid drop in immiscible liquid, range rigid to fully circulating	$N_{Sh,c,\text{rigid}} = \dfrac{k_c d_p}{D_c} = 2.43 + 0.774 N_{Re}^{0.5} N_{Sc}^{0.33}$ $+ 0.0103 N_{Re} N_{Sc}^{0.33}$ $N_{Sh,c,\text{fully circular}} = \left[\dfrac{2}{\pi^{0.5}}\right] N_{Pe,c}^{0.5}$ Drops in intermediate range: $\dfrac{N_{Sh,c} - N_{Sh,c,\text{rigid}}}{N_{Sh,c,\text{fully circular}} - N_{Sh,c,\text{rigid}}} = 1 - \exp\left[-(4.18 \times 10^{-3}) N_{Pe,c}^{0.42}\right]$	[E] Allows for slight effect of wake. Rigid drops: $10^4 < N_{Pe,c} < 10^6$ Circulating drops: $10 < N_{Re} < 1200$, $190 < N_{Sc} < 241{,}000$, $10^3 < N_{Pe,c} < 10^6$	[146] p. 58
S. Coalescing drops in immiscible liquid, discontinuous phase coefficient	$\hat{k}_{d,\text{coal}} = 0.173 \dfrac{d_p}{t_f}\left(\dfrac{\rho_d}{M_d}\right)_{av}\left(\dfrac{\mu_d}{\rho_d D_d}\right)^{-1.115}$ $\times \left(\dfrac{\Delta\rho g d_p^2}{\sigma g_c}\right)^{1.302}\left(\dfrac{v_s^2 t_f}{D_d}\right)^{0.146}$	[E] Used with log mean mole fraction difference. 23 data points. Average absolute deviation 25%. t_f = formation time.	[141] p. 408
T. Same as 5-21-S, continuous phase coefficient	$\hat{k}_{c,\text{coal}} = 5.959 \times 10^{-4}\left(\dfrac{\rho}{M}\right)_{av}$ $\times \left(\dfrac{D_c}{t_f}\right)^{0.5}\left(\dfrac{\rho_d u_s^3}{g\mu_c}\right)^{0.332}\left(\dfrac{d_p^2 \rho_c \rho_d v_s^3}{\mu_d \sigma g_c}\right)^{0.525}$	[E] Used with log mean mole fraction difference. 20 data points. Average absolute deviation 22%.	[141] p. 409

TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns (*Continued*)

Conditions	Correlations	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
U. Single liquid drops in gas, gas side coefficient	$\frac{\hat{k}_g M_g d_p P}{D_{gas}\rho_g} = 2 + A N_{Re,g}^{1/2} N_{Sc,g}^{1/3}$ A = 0.552 or 0.60. $N_{Re,g} = \frac{d_p \rho_g v_s}{\mu_g}$	[E] Used for spray drying (arithmetic partial pressure difference). v_s = slip velocity between drop and gas stream. Sometimes written with $M_g P/\rho_g = RT$.	[90] p. 388 [121]
V. Single water drop in air, liquid side coefficient	$k_L = 2\left(\frac{D_L}{\pi t}\right)^{1/2}$, short contact times $k_L = 10\,\frac{D_L}{d_p}$, long contact times	[T] Use arithmetic concentration difference. Penetration theory. t = contact time of drop. Gives plot for $k_G a$ also. Air-water system.	[90] p. 389
W. Single bubbles of gas in liquid, continuous phase coefficient, very small bubbles	$N_{Sh} = \frac{k_c' d_b}{D_c} = 1.0(N_{Re}N_{Sc})^{1/3}$	[T] Solid-sphere Eq. (see Table 5-20-B). $d_b < 0.1$ cm, k_c' is average over entire surface of bubble.	[105] [138] p. 214
X. Same as 5-21-W, medium to large bubbles	$N_{Sh} = \frac{k_c' d_b}{D_c} = 1.13(N_{Re}N_{Sc})^{1/2}$	[T] Use arithmetic concentration difference. Droplet equation: $d_b > 0.5$ cm.	[138] p. 231
Y. Same as 5-21-X	$N_{Sh} = \frac{k_c' d_b}{D_c} = 1.13(N_{Re}N_{Sc})^{1/2}\left[\frac{d_b}{0.45 + 0.2 d_b}\right]$ $500 \le N_{Re} \le 8000$	[S] Use arithmetic concentration difference. Modification of above (X), $d_b > 0.5$ cm. No effect SAA for $d_p > 0.6$ cm.	[83][138] p. 231
Z. Taylor bubbles in single capillaries (square or circular)	$k_L a = 4.5\left(\frac{D u_G}{L_{uc}}\right)^{1/2} \frac{1}{d_c}$ Applicable $\left(\frac{u_G + u_L}{L_{slug}}\right)^{0.5} > 3 s^{-0.5}$	[E] Air-water L_{uc} = unit cell length, L_{slug} = slug length, d_c = capillary i.d. For most data $k_L a \pm 20\%$.	[153]
AA. Gas-liquid mass transfer in monoliths	$k_L a \approx 0.1\left(\frac{P}{V}\right)^{1/4}$ P/V = power/volume (kW/m^3), range = 100 to 10,000	[E] Each channel in monolith is a capillary. Results are in expected order of magnitude for capillaries based on 5-21-Z. k_L is larger than in stirred tanks.	[93]
AB. Rising small bubbles of gas in liquid, continuous phase. Calderbank and Moo-Young correlation	$N_{Sh} = \frac{k_c' d_b}{D_c} = 2 + 0.31(N_{Gr})^{1/3} N_{Sc}^{1/3}$, $d_b < 0.25$ cm $N_{Ra} = \frac{d_b^3 \lvert\rho_G - \rho_L\rvert g}{\mu_L D_L}$ = Raleigh number	[E] Use with arithmetic concentration difference. Valid for single bubbles or swarms. Independent of agitation as long as bubble size is constant. Recommended by [136]. Note that $N_{Ra} = N_{Gr} N_{Sc}$.	[47][66] p. 451 [88] p. 119 [152] p. 156 [136]
AC. Same as 5-21-AB, large bubbles	$N_{Sh} = \frac{k_c' d_b}{D_c} = 0.42\,(N_{Gr})^{1/3} N_{Sc}^{1/2}$, $d_b > 0.25$ cm $\frac{\text{Interfacial area}}{\text{volume}} = a = \frac{6\,H_g}{d_b}$	[E] Use with arithmetic concentration difference. For large bubbles, k_c' is independent of bubble size and independent of agitation or liquid velocity. Resistance is entirely in liquid phase for most gas-liquid mass transfer. H_g = fractional gas holdup, volume gas/total volume.	[47][66] p. 452 [88] p. 119 [97] p. 249 [136]
AD. Bubbles in bubble columns. Hughmark correlation	$N_{Sh} = \frac{k_L d}{D} = 2 + b N_{Sc}^{0.546} N_{Re}^{0.779}\left(\frac{d g^{1/3}}{D^{2/3}}\right)^{0.116}$ $b = 0.061$ single gas bubbles; $b = 0.0187$ swarms of bubbles, $V_s = \frac{V_g}{\varphi_G} - \frac{V_L}{1 - \varphi_G}$	[E] d = bubble diameter Air–liquid. Recommended by [136, 152]. For swarms, calculate N_{Re} with slip velocity V_s. φ_G = gas holdup V_G = superficial gas velocity Col. diameter = 0.025 to 1.1 m ρ_L' = 776 to 1696 kg/m^3 μ_L = 0.0009 to 0.152 Pa·s	[55] [82] [152] p. 144
AE. Bubbles in bubble column	$k_L a = 0.00315 u_G^{0.59}\,\mu_{eff}^{-0.84}$	[E] Recommended by [136].	[57]

TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns (*Concluded*)

Conditions	Correlations	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
AF. Bubbles in bubble column	$k_L = \frac{0.15D}{d_{Vs}}\left(\frac{\nu}{D}\right)^{1/2} N_{Re}^{3/4}$	[E] d_{Vs} = Sauter mean bubble diameter, $N_{Re} = d_{Vs}u_G\rho_L/\mu_L$. Recommended by [49] based on experiments in industrial system.	[49] [133]
AG. High-pressure bubble column	$k_La = 1.77\sigma^{-0.22}\exp(1.65u_\ell - 65.3\mu_\ell)\varepsilon_g^{1.2}$ $790 < \rho_L < 1580$ kg/m^3 $0.00036 < \mu_\ell < 0.0383$ Pa·s $0.0232 < \sigma_\ell < 0.0726$ N/m $0.028 < u_g < 0.678$ m/s $0 < u_\ell < 0.00089$ m/s	[E] Pressure up to 4.24 MPa. T up to 92°C. ε_g = gas holdup. Correlation to estimate ε_g is given. $0.045 < d_{col} < 0.45$ m, $d_{col}/H_{col} > 5$ $0.97 < \rho_g < 33.4$ kg/m^3	[96]
AH. Three phase (gas-liquid-solid) bubble column to solid spheres	$N_{sh} = \frac{k_s d_p}{D} = 2.0 + 0.545 N_{Sc}^{1/3}\left(\frac{e d_p^4}{\nu^3}\right)^{0.264}$ N_{Sc} = 137 to 50,000 (very wide range) d_p = particle diameter (solids)	[E] e = local energy dissipation rate/unit mass, $e = u_g g$ $N_{Sc} = \mu_L/(\rho_L D)$ Recommended by [136].	[129] [136]

See Table 5-22 for agitated systems.
*See the beginning of the "Mass Transfer" subsection for references.

practical purposes $\hat{k}_G$ is independent of temperature and pressure in the normal ranges of these variables.

For modest changes in temperature the influence of temperature upon the interfacial area a may be neglected. For example, in experiments on the absorption of SO_2 in water, Whitney and Vivian [*Chem. Eng. Prog.*, **45,** 323 (1949)] found no appreciable effect of temperature upon k'_Ga over the range from 10 to 50°C.

With regard to the liquid-phase mass-transfer coefficient, Whitney and Vivian found that the effect of temperature upon k_La could be explained entirely by variations in the liquid-phase viscosity and diffusion coefficient with temperature. Similarly, the oxygen-desorption data of Sherwood and Holloway [*Trans. Am. Inst. Chem. Eng.*, **36,** 39 (1940)] show that the influence of temperature upon H_L can be explained by the effects of temperature upon the liquid-phase viscosity and diffusion coefficients (see Table 5-24-A).

It is important to recognize that the effects of temperature on the liquid-phase diffusion coefficients and viscosities can be very large and therefore must be carefully accounted for when using $\hat{k}_L$ or H_L data. For liquids the mass-transfer coefficient $\hat{k}_L$ is correlated as either the Sherwood number or the Stanton number as a function of the Reynolds and Schmidt numbers (see Table 5-24). Typically, the general form of the correlation for H_L is (Table 5-24)

$$H_L = bN_{Re}^a N_{Sc}^{1/2} \tag{5-306}$$

where b is a proportionality constant and the exponent a may range from about 0.2 to 0.5 for different packings and systems. The liquid-phase diffusion coefficients may be corrected from a base temperature T_1 to another temperature T_2 by using the Einstein relation as recommended by Wilke [*Chem. Eng. Prog.*, **45,** 218 (1949)]:

$$D_2 = D_1(T_2/T_1)(\mu_1/\mu_2) \tag{5-307}$$

The Einstein relation can be rearranged to the following equation for relating Schmidt numbers at two temperatures:

$$N_{Sc2} = N_{Sc1}(T_1/T_2)(\rho_1/\rho_2)(\mu_2/\mu_1)^2 \tag{5-308}$$

Substitution of this relation into Eq. (5-306) shows that for a given geometry the effect of temperature on H_L can be estimated as

$$H_{L2} = H_{L1}(T_1/T_2)^{1/2}(\rho_1/\rho_2)^{1/2}(\mu_2/\mu_1)^{1-a} \tag{5-309}$$

In using these relations it should be noted that for equal liquid flow rates

$$H_{L2}/H_{L1} = (\hat{k}_La)_1/(\hat{k}_La)_2 \tag{5-310}$$

Effects of System Physical Properties on $\hat{k}_G$ and $\hat{k}_L$ When designing packed towers for nonreacting gas-absorption systems for which no experimental data are available, it is necessary to make corrections for differences in composition between the existing test data and the system in question. The ammonia-water test data (see Table 5-24-B) can be used to estimate H_G, and the oxygen desorption data (see Table 5-24-A) can be used to estimate H_L. The method for doing this is illustrated in Table 5-24-E. There is some conflict on whether the value of the exponent for the Schmidt number is 0.5 or 2/3 [Yadav and Sharma, *Chem. Eng. Sci.* **34,** 1423 (1979)]. Despite this disagreement, this method is extremely useful, especially for absorption and stripping systems.

It should be noted that the influence of substituting solvents of widely differing viscosities upon the interfacial area a can be very large. One therefore should be cautious about extrapolating $\hat{k}_La$ data to account for viscosity effects between different solvent systems.

Effects of High Solute Concentrations on $\hat{k}_G$ and $\hat{k}_L$ As discussed previously, the stagnant-film model indicates that $\hat{k}_G$ should be independent of y_{BM} and k_G should be inversely proportional to y_{BM}. The data of Vivian and Behrman [*Am. Inst. Chem. Eng. J.*, **11,** 656 (1965)] for the absorption of ammonia from an inert gas strongly suggest that the film model's predicted trend is correct. This is another indication that the most appropriate rate coefficient to use in concentrated systems is $\hat{k}_G$ and the proper driving-force term is of the form $(y - y_i)/y_{BM}$.

The use of the rate coefficient $\hat{k}_L$ and the driving force $(x_i - x)/x_{BM}$ is believed to be appropriate. For many practical situations the liquid-phase solute concentrations are low, thus making this assumption unimportant.

Influence of Chemical Reactions on $\hat{k}_G$ and $\hat{k}_L$ When a chemical reaction occurs, the transfer rate may be influenced by the chemical reaction as well as by the purely physical processes of diffusion and convection within the two phases. Since this situation is common in gas absorption, gas absorption will be the focus of this discussion. One must consider the impacts of chemical equilibrium and reaction kinetics on the absorption rate in addition to accounting for the effects of gas solubility, diffusivity, and system hydrodynamics.

There is no sharp dividing line between pure physical absorption and absorption controlled by the rate of a chemical reaction. Most cases fall in an intermediate range in which the rate of absorption is limited both by the resistance to diffusion and by the finite velocity of the reaction. Even in these intermediate cases the equilibria between the various diffusing species involved in the reaction may affect the rate of absorption.

TABLE 5-22 Mass-Transfer Correlations for Particles, Drops, and Bubbles in Agitated Systems

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
A. Solid particles suspended in agitated vessel containing vertical baffles, continuous phase coefficient	$\frac{k'_{LT}\, d_p}{D} = 2 + 0.6 N_{Re,T}^{1/2} N_{Sc}^{1/3}$ Replace v_{slip} with v_T = terminal velocity. Calculate Stokes' law terminal velocity $v_{Ts} = \frac{d_p^2 \lvert\rho_p - \rho_c\rvert g}{18\mu_c}$ and correct: $N_{Re,Ts}$: 1 | 10 | 100 | 1,000 | 10,000 | 100,000 v_T/v_{Ts}: 0.9 | 0.65 | 0.37 | 0.17 | 0.07 | 0.023 Approximate: $k'_L = 2k'_{LT}$	[S] Use log mean concentration difference. Modified Frossling equation: $N_{Re,Ts} = \frac{v_{Ts} d_p \rho_c}{\mu_c}$ (Reynolds number based on Stokes' law.) $N_{Re,T} = \frac{v_T d_p \rho_c}{\mu_c}$ (terminal velocity Reynolds number.) k'_L almost independent of d_p. Harriott suggests different correction procedures. Range k'_L/k'_{LT} is 1.5 to 8.0.	[74][138] p. 220–222 [110] [74]
B. Solid, neutrally buoyant particles, continuous phase coefficient	$N_{Sh} = \frac{k'_L d_p}{D} = 2 + 0.47 N_{Re,p}^{0.62} N_{Sc}^{0.36} \left(\frac{d_{imp}}{d_{tank}}\right)^{0.17}$ Graphical comparisons are in Ref. 88, p. 116.	[E] Use log mean concentration difference. Density unimportant if particles are close to neutrally buoyant. Also used for drops. Geometric effect (d_{imp}/d_{tank}) is usually unimportant. Ref. 102 gives a variety of references on correlations. [E] E = energy dissipation rate per unit mass fluid $= \frac{Pg_c}{V_{tank}\rho_c}$, P = power, $N_{Re,p} = \frac{E^{1/3} d_p^{4/3}}{\nu}$	[88] p. 115 [102] p. 132 [152] p. 523
C. Same as 22-B, small particles	$N_{Sh} = 2 + 0.52 N_{Re,p}^{0.52} N_{Sc}^{1/3}$, $N_{Re,p} < 1.0$	[E] Terms same as above.	[88] p. 116
D. Solid particles with significant density difference	$N_{Sh} = \frac{k'_L\, d_p}{D} = 2 + 0.44 \left(\frac{d_p v_{slip}}{\nu}\right)^{1/2} N_{Sc}^{0.38}$	[E] Use log mean concentration difference. N_{Sh} standard deviation 11.1%. v_{slip} calculated by methods given in reference.	[102] [110]
E. Small solid particles, gas bubbles or liquid drops, $d_p < 2.5$ mm. Aerated mixing vessels	$N_{Sh} = \frac{k'_L d_p}{D} = 2 + 0.31 \left[\frac{d_p^3 \lvert\rho_p - \rho_c\rvert}{\mu_c D}\right]^{1/3}$	[E] Use log mean concentration difference. $g = 9.80665$ m/s^2. Second term RHS is free-fall or rise term. For large bubbles, see Table 5-21-AC.	[46][67] p. 487 [97] p. 249
F. Highly agitated systems; solid particles, drops, and bubbles; continuous phase coefficient	$k'_L N_{Sc}^{2/3} = 0.13 \left[\frac{(P/V_{tank})\mu_c g_c}{\rho_c^2}\right]^{1/4}$	[E] Use arithmetic concentration difference. Use when gravitational forces overcome by agitation. Up to 60% deviation. Correlation prediction is low (Ref. 102). (P/V_{tank}) = power dissipated by agitator per unit volume liquid.	[47] [66] p. 489 [110]
G. Liquid drops in baffled tank with flat six-blade turbine	$k'_c a = 2.621 \times 10^{-3} \frac{(ND)^{1/2}}{d_{imp}} \times \phi^{0.304} \left(\frac{d_{imp}}{d_{tank}}\right)^{1.582} N_{Re}^{1.929} N_{Oh}^{1.025}$	[E] Use arithmetic concentration difference. Studied for five systems. $N_{Re} = d_{imp}^2 N\rho_c/\mu_c$, $N_{Oh} = \mu_c/(\rho_c d_{imp}\sigma)^{1/2}$ ϕ = volume fraction dispersed phase. N = impeller speed (revolutions/time). For $d_{tank} = h_{tank}$, average absolute deviation 23.8%.	[144] p. 437
H. Liquid drops in baffled tank, low volume fraction dispersed phase	$N_{Sh} = \frac{k'_c d_p}{D} = 1.237 \times 10^{-5} N_{Sc}^{1/3} N^{2/3} \times N_{Fr}^{5/12} \left(\frac{d_{imp}}{d_p}\right) \left(\frac{d_p}{D_{tank}}\right)^{1/2} \left(\frac{\rho_d d_p^2}{\sigma}\right)^{5/4} \phi^{-1/2}$ Stainless steel flat six-blade turbine. Tank had four baffles. Correlation recommended for $\phi \le 0.06$ [Ref. 146] $a = 6\phi/\hat{d}_{32}$, where $\hat{d}_{32}$ is Sauter mean diameter when 33% mass transfer has occurred.	[E] 180 runs, 9 systems, $\phi = 0.01$. k_c is time-averaged. Use arithmetic concentration difference. $N_{Re} = \left(\frac{d_{imp}^2 N_{Sc}}{\mu_c}\right)$, $N_{Fr} = \left(\frac{d_{imp} N^2}{g}\right)$ d_p = particle or drop diameter; σ = interfacial tension, N/m; ϕ = volume fraction dispersed phase; a = interfacial volume, 1/m; and $k_c \alpha D_c^{2/3}$ implies rigid drops. Negligible drop coalescence. Average absolute deviation—19.71%. Graphical comparison given by Ref. 143.	[143] [146] p. 78

TABLE 5-22 Mass-Transfer Correlations for Particles, Drops, and Bubbles in Agitated Systems (*Concluded*)

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
I. Gas bubble swarms in sparged tank reactors	$k'_L a\left(\frac{\nu}{g^2}\right)^{1/3} = C\left[\frac{P/V_L}{\rho(\nu g^4)^{1/3}}\right]^a \left[\frac{q_G}{V_L}\left(\frac{\nu}{g^2}\right)^{1/3}\right]^b$ Rushton turbines: $C = 7.94 \times 10^{-4}$, $a = 0.62$, $b = 0.23$. Intermig impellers: $C = 5.89 \times 10^{-4}$, $a = 0.62$, $b = 0.19$.	[E] Use arithmetic concentration difference. Done for biological system, O_2 transfer. $h_{tank}/D_{tank} = 2.1$; P = power, kW. V_L = liquid volume, m^3. q_G = gassing rate, m^3/s. $k'_L a = s^{-1}$. Since $a = m^2/m^3$, ν = kinematic viscosity, m^2/s. Low viscosity system. Better fit claimed with q_G/V_L than with u_G (see 5-22-J to N).	[131]
J. Same as 5-22-I	$k'_L a = 2.6 \times 10^{-2}\left(\frac{P}{V_L}\right)^{0.4} u_G^{0.5}$	[E] Use arithmetic concentration difference. Ion free water $V_L < 2.6$, u_G = superficial gas velocity in m/s. $500 < P/V_L < 10{,}000$. P/V_L = watts/m^3, V_L = liquid volume, m^3.	[98] [123]
K. Same as 5-22-J	$k'_L a = 2.0 \times 10^{-3}\left(\frac{P}{V_L}\right)^{0.7} u_G^{0.2}$	[E] Use arithmetic concentration difference. Water with ions. $0.002 < V_L < 4.4$, $500 < P/V_L < 10{,}000$. Same definitions as 5-22-I.	[98] [101]
L. Same as 5-22-I, baffled tank with standard blade Rushton impeller	$k'_L a = 93.37\left(\frac{P}{V_L}\right)^{0.76} u_G^{0.45}$	[E] Air-water. Same definitions as 5-22-I. $0.005 < u_G < 0.025$, $3.83 < N < 8.33$, $400 < P/V_L < 7000$ $h = D_{tank} = 0.305$ or 0.610 m. V_G = gas volume, m^3, N = stirrer speed, rpm. Method assumes perfect liquid mixing.	[67] [98]
M. Same as 5-22-L	$k'_L a\,\frac{d^2_{imp}}{D} = 7.57\left[\frac{\mu_{eff}}{\rho D}\right]^{0.5}\left[\frac{\mu_G}{\mu_{eff}}\right]^{0.694} \times \left[\frac{d^2_{imp} N \rho_L}{\mu_{eff}}\right]^{1.11}\left(\frac{u_G d}{\sigma}\right)^{0.447}$ d_{imp} = impeller diameter, m; D = diffusivity, m^2/s	[E] Use arithmetic concentration difference. CO_2 into aqueous carboxyl polymethylene. Same definitions as 5-22-L. μ_{eff} = effective viscosity from power law model, Pa·s. σ = surface tension liquid, N/m.	[98] [115]
N. Same as 5-22-L, bubbles	$\frac{k'_L a d^2_{imp}}{D} = 0.060\left(\frac{d^2_{imp} N \rho}{\mu_{eff}}\right)\left(\frac{d^2_{imp} N^2}{g}\right)^{0.19}\left(\frac{\mu_{eff} u_G}{\sigma}\right)^{0.6}$	[E] Use arithmetic concentration difference. O_2 into aqueous glycerol solutions. O_2 into aqueous millet jelly solutions. Same definitions as 5-22-L.	[98] [160]
O. Gas bubble swarm in sparged stirred tank reactor with solids present	$\frac{k'_L a}{(k'_L a)_o} = 1 - 3.54(\varepsilon_s - 0.03)$ $300 \le P/V_{rx} < 10{,}000$ W/m^3, $0.03 \le \varepsilon_s \le 0.12$ $0.34 \le u_G \le 4.2$ cm/s, $5 < \mu_L < 75$ Pa·s	[E] Use arithmetic concentration difference. Solids are glass beads, $d_p = 320$ μm. ε_s = solids holdup m^3/m^3 liquid, $(k'_L a)_o$ = mass transfer in absence of solids. Ionic salt solution—noncoalescing.	[38] [132]
P. Surface aerators for air-water contact	$\frac{k_L a}{N} = b N_p^{0.71} N_{Fr}^{0.48} N_{Re}^{0.82}\left(\frac{H}{d}\right)^{-0.54}\left(\frac{V}{d^3}\right)^{-1.08}$ $b = 7 \times 10^{-6}$, $N_p = P/(\rho N^3 d^5)$ $N_{Re} = N d^2 \rho_{liq}/\mu_{liq}$ $N_{Fr} = N^2 d/g$, $P/V = 90$ to 400 W/m^3	[E] Three impellers: Pitched blade downflow turbine, pitched blade upflow turbine, standard disk turbine. Baffled cylindrical tanks 1.0- and 1.5-m ID and 8.2 × 8.2-m square tank. Submergence optimized all cases. Good agreement with data. N = impeller speed, s^{-1}; d = impeller diameter, m; H = liquid height, m; V = liquid volume, m^3; $k_L a = s^{-1}$, g = acceleration gravity = 9.81 m/s^2	[113]
Q. Gas-inducing impeller for air-water contact	$k_L a V(v/g^2)^{1/3} d^3 = A N_{Fr}^B\left(\frac{V_A}{V}\right)^C$ Single impeller: $A = 0.00497$, $B = 0.56$, $C = 0.32$ Multiple impeller: $A = 0.00746$, $B = 0.54$, $C = 0.38$	[E] Same tanks and same definitions as in 5-22-P. V_A = active volume = $p/(\pi \rho g N d)$.	[113]
R. Gas-inducing impeller with dense solids	$Sh_{GL} = \frac{k_L a d^2_{st}}{D} = (1.26 \times 10^{-5})\, N_{Re}^{1.8} N_{Sc}^{0.9} N_{We}^{-0.1}$ $N_{Re} = \rho N d^2_{St}/\mu$, $N_{Sc} = \mu/(\rho D)$, $N_{We} = \rho N^2 d^2_{St}/\sigma$	[E] Hydrogenation with Raney-type nickel catalyst in stirred autoclave. Used varying T, p, solvents. d_{st} = stirrer diameter.	[78]

See also Table 5-21.

TABLE 5-23 Mass-Transfer Correlations for Fixed and Fluidized Beds

Transfer is to or from particles

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
A. For gases, fixed and fluidized beds, Gupta and Thodos correlation	$j_H = j_D = \frac{2.06}{\varepsilon N_{Re}^{0.575}}$, $90 \le N_{Re} \le A$ Equivalent: $N_{Sh} = \frac{2.06}{\varepsilon} N_{Re}^{0.425} N_{Sc}^{1/3}$ For other shapes: $\frac{\varepsilon j_D}{(\varepsilon j_D)_{\text{sphere}}} = 0.79$ (cylinder) or 0.71 (cube)	[E] For spheres. $N_{Re} = \frac{v_{\text{super}} d_p \rho}{\mu}$ $A = 2453$ [Ref. 141], $A = 4000$ [Ref. 77]. For $N_{Re} > 1900$, $j_H = 1.05 j_D$. Heat transfer result is in absence of radiation. $N_{Sh} = \frac{k' d_s}{D}$ Graphical results are available for N_{Re} from 1900 to 10,300. $a = \frac{\text{surface area}}{\text{volume}} = 6(1 - \varepsilon)/d_p$ For spheres, d_p = diameter. For nonspherical: $d_p = 0.567 \sqrt{\text{Part. Surf. Area}}$	[72] [73] [77] p. 195 [141]
B. For gases, for fixed beds, Petrovic and Thodos correlation	$N_{Sh} = \frac{0.357}{\varepsilon} N_{Re}^{0.641} N_{Sc}^{1/3}$ $3 < N_{Re} < 900$ can be extrapolated to $N_{Re} < 2000$.	[E] Packed spheres, deep beds. Corrected for axial dispersion with axial Peclet number = 2.0. Prediction is low at low N_{Re}. N_{Re} defined as in 5-23-A.	[116][128] p. 214 [155]
C. For gases and liquids, fixed and fluidized beds	$j_D = \frac{0.4548}{\varepsilon N_{Re}^{0.4069}}$, $10 \le N_{Re} \le 2000$ $j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$, $N_{Sh} = \frac{k' d_s}{D}$	[E] Packed spheres, deep bed. Average deviation $\pm 20\%$, $N_{Re} = d_p v_{\text{super}} \rho/\mu$. Can use for fluidized beds. $10 \le N_{Re} \le 4000$.	[60][66] p. 484
D. For gases, fixed beds	$j_D = \frac{0.499}{\varepsilon N_{Re}^{0.382}}$	[E] Data on sublimination of naphthalene spheres dispersed in inert beads. $0.1 < N_{Re} < 100$, $N_{Sc} = 2.57$. Correlation coefficient = 0.978.	[80]
E. For liquids, fixed bed, Wilson and Geankoplis correlation	$j_D = \frac{1.09}{\varepsilon N_{Re}^{2/3}}$, $0.0016 < N_{Re} < 55$ $165 \le N_{Sc} \le 70{,}600$, $0.35 < \varepsilon < 0.75$ Equivalent: $N_{Sh} = \frac{1.09}{\varepsilon} N_{Re}^{1/3} N_{Sc}^{1/3}$ $j_D = \frac{0.25}{\varepsilon N_{Re}^{0.31}}$, $55 < N_{Re} < 1500$, $165 \le N_{Sc} \le 10{,}690$ Equivalent: $N_{Sh} = \frac{0.25}{\varepsilon} N_{Re}^{0.69} N_{Sc}^{1/3}$	[E] Beds of spheres, $N_{Re} = \frac{d_p V_{\text{super}} \rho}{\mu}$ Deep beds. $N_{Sh} = \frac{k' d_s}{D}$	[66] p. 484 [77] p. 195 [141] p. 287 [158]
F. For liquids, fixed beds, Ohashi et al. correlation	$N_{Sh} = \frac{k' d_s}{D} = 2 + 0.51\left(\frac{E^{1/3} d_p^{4/3} \rho}{\mu}\right)^{0.60} N_{Sc}^{1/3}$ E = Energy dissipation rate per unit mass of fluid $= 50(1 - \varepsilon)\varepsilon^2 C_{Do}\left(\frac{v_r^3}{d_p}\right)$, m²/s³ $= \left[\frac{50(1 - \varepsilon) C_D}{\varepsilon}\right]\left(\frac{v_{\text{super}}^3}{d_p}\right)$ General form: $N_{Sh} = 2 + K\left(\frac{E^{1/3} D_p^{4/3} \rho}{\mu}\right)^{\alpha} N_{Sc}^{\beta}$ applies to single particles, packed beds, two-phase tube flow, suspended bubble columns, and stirred tanks with different definitions of E.	[S] Correlates large amount of published data. Compares number of correlations, v_r = relative velocity, m/s. In packed bed, $v_r = v_{\text{super}}/\varepsilon$. C_{Do} = single particle drag coefficient at v_{super} calculated from $C_{Do} = A N_{Re_i}^{-m}$. N_{Re} / A / m: 0 to 5.8 / 24 / 1.0 5.8 to 500 / 10 / 0.5 >500 / 0.44 / 0 Ranges for packed bed: $0.001 < N_{Re} < 1000$, $505 < N_{Sc} < 70{,}600$, $0.2 < \frac{E^{1/3} d_p^{4/3} \rho}{\mu} < 4600$ Compares different situations versus general correlation. See also 5-20-F.	[108]

TABLE 5-23 Mass Transfer Correlations for Fixed and Fluidized Beds (*Continued*)

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
G. Electrolytic system. Pall rings. Transfer from fluid to rings.	Full liquid upflow: $N_{sh} = k_L d_e/D = 4.1 N_{Re}^{0.39} N_{Sc}^{1/3}$ $N_{Re} d_e u/\nu = 80$ to 550 Irrigated liquid downflow (no gas flow): $N_{Sh} = 5.1 N_{Re}^{0.44} N_{Sc}^{1/3}$	[E] d_e = diameter of sphere with same surface area as Pall ring. Full liquid upflow agreed with literature values. Schmidt number dependence was assumed from literature values. In downflow, N_{Re} used superficial fluid velocity.	[69]
H. For liquids, fixed and fluidized beds	$\varepsilon j_D = \frac{1.1068}{N_{Re}^{0.72}}$, $1.0 < N_{Re} \le 10$ $\varepsilon j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$, $N_{Sh} = \frac{k' d_s}{D}$	[E] Spheres: $N_{Re} = \frac{d_p v_{\text{super}} \rho}{\mu}$	[59][66] p. 484
I. For gases and liquids, fixed and fluidized beds, Dwivedi and Upadhyay correlation	$\varepsilon j_D = \frac{0.765}{N_{Re}^{0.82}} + \frac{0.365}{N_{Re}^{0.386}}$ Gases: $10 \le N_{Re} \le 15{,}000$. Liquids: $0.01 \le N_{Re} \le 15{,}000$. $N_{Re} = \frac{d_p v_{\text{super}} \rho}{\mu}$, $N_{Sh} = \frac{k' d_s}{D}$	[E] Deep beds of spheres, $j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$ Best fit correlation at low conc. [52] Based on 20 gas studies and 17 liquid studies. Recommended instead of 5-23-C or E.	[59] [77] p. 196 [52]
J. For gases and liquids, fixed bed	$j_D = 1.17 N_{Re}^{-0.415}$, $10 \le N_{Re} \le 2500$ $j_D = \frac{k'}{v_{av}} \frac{p_{BM}}{P} N_{Sc}^{2/3}$	[E] Spheres: Variation in packing that changes ε not allowed for. Extensive data referenced. $0.5 < N_{Sc} < 15{,}000$. Comparison with other results are shown. $N_{Re} = \frac{d_p v_{\text{super}} \rho}{\mu}$	[138] p. 241
K. For liquids, fixed and fluidized beds, Rahman and Streat correlation	$N_{Sh} = \frac{0.86}{\varepsilon} N_{Re} N_{Sc}^{1/3}$, $2 \le N_{Re} \le 25$	[E] Can be extrapolated to $N_{Re} = 2000$. $N_{Re} = d_p v_{\text{super}} \rho/\mu$. Done for neutralization of ion exchange resin.	[119]
L. Size exclusion chromatography of proteins	$N_{Sh} = \frac{k_L d}{D} = \frac{1.903}{\varepsilon} N_{Re}^{1/3} N_{Sc}^{1/3}$	[E] Slow mass transfer with large molecules. Aqueous solutions. Modest increase in N_{Sh} with increasing velocity.	[79]
M. Liquid-free convection with fixed bed Raschig rings. Electrochemical.	$N_{Sh} = kd/D = 0.15\,(N_{Sc} N_{Gr})^{0.32}$ N_{Gr} = Grashof no. = $gd^3 \Delta\rho/(\nu^2 \rho)$ If forced convection superimposed, $N_{Sh,\text{ overall}} = (N_{Sh,\text{forced}}^3 + N_{Sh,\text{free}}^3)^{1/3}$	[E] d = Raschig ring diameter, h = bed height $1810 < N_{Sc} < 2532$, $0.17 < d/h < 1.0$ $10.6 \times 10^6 < N_{Sc} N_{Gr} < 21 \times 10^7$	[135]
N. Oscillating bed packed with Raschig rings. Dissolution of copper rings.	Batch (no net solution flow): $N_{Sh} = 0.76 N_{Sc}^{0.33} N_{Re,v}^{0.7} (d_c/h)^{0.35}$ $503 < N_{Re,v} < 2892$ $960 < N_{Sc} < 1364$, $2.3 < d_c/h < 7.6$	[E] $N_{Sh} = kd_c/D$, $N_{Re,v}$ = vibrational Re = $\rho v_v d_c/\mu$ v_v = vibrational velocity (intensity) d_c = col. diameter, h = column height Average deviation is ± 12%.	[61]
O. For liquids and gases, Ranz and Marshall correlation	$N_{Sh} = \frac{k' d}{D} = 2.0 + 0.6 N_{Sc}^{1/3} N_{Re}^{1/2}$ $N_{Re} = \frac{d_p v_{\text{super}} \rho}{\mu}$	[E] Based on freely falling, evaporating spheres (see 5-20-C). Has been applied to packed beds, prediction is low compared to experimental data. Limit of 2.0 at low N_{Re} is too high. Not corrected for axial dispersion.	[121][128] p. 214 [155] [110]
P. For liquids and gases, Wakao and Funazkri correlation	$N_{Sh} = 2.0 + 1.1 N_{Sc}^{1/3} N_{Re}^{0.6}$, $3 < N_{Re} < 10{,}000$ $N_{Sh} = \frac{k'_{\text{film}} d_p}{D}$, $N_{Re} = \frac{\rho_f v_{\text{super}} \rho}{\mu}$ $\frac{\varepsilon D_{\text{axial}}}{D} = 10 + 0.5 N_{Sc} N_{Re}$	[E] Correlate 20 gas studies and 16 liquid studies. Corrected for axial dispersion with: Graphical comparison with data shown [128], p. 215, and [155]. D_{axial} is axial dispersion coefficient.	[128] p. 214 [155]
Q. Acid dissolution of limestone in fixed bed	$N_{Sh} = 1.77\, N_{Re}^{0.56} N_{Sc}^{1/3} (1 - \varepsilon)^{0.44}$ $20 < N_{Re} < 6000$	[E] Best fit was to correlation of Chu et al., *Chem. Eng. Prog.*, **49**(3), 141(1953), even though no reaction in original.	[94]
R. Semifluidized or expanded bed. Liquid-solid transfer.	$N_{Sh} = \frac{k_{\text{film}} d_p}{D} = 2 + 1.5\,(1 - \varepsilon_L) N_{Re}^{1/3} N_{Sc}^{1/3}$ $N_{Re} = \rho_p d_p u/\mu\varepsilon_L$; $N_{Sc} = \mu/\rho D$	[E] ε_L = liquid-phase void fraction, ρ_p = particle density, ρ = fluid density, d_p = particle diameter. Fits expanded bed chromatography in viscous liquids.	[64] [159]

TABLE 5-23 Mass Transfer Correlations for Fixed and Fluidized Beds (*Concluded*)

Situation	Correlation	Comments E = Empirical, S = Semiempirical, T = Theoretical	References*
S. Mass-transfer structured packing and static mixers. Liquid with or without fluidized particles. Electrochemical	Fixed bed: $j' = 0.927N_{Re'}^{0.572}$, $N'_{Re} < 219$ $j' = 0.443N_{Re'}^{-0.435}$, $219 < N'_{Re} < 1360$ Fluidized bed with particles: $j = 6.02N_{Re}^{-0.885}$, or $j' = 16.40N_{Re'}^{-0.950}$ Natural convection: $N_{Sh} = 0.252(N_{Sc}N_{Gr})^{0.299}$ Bubble columns: Structured packing: $N_{St} = 0.105(N_{Re}N_{Fr}N_{Sc}^2)^{-0.268}$ Static mixer: $N_{St} = 0.157(N_{Re}N_{Fr}N_{Sc}^2)^{-0.298}$	[E] Sulzer packings, $j' = \dfrac{k \cos \beta}{v} N_{Sc}^{2/3}$, β = corrugation incline angle. $N_{Re'} = v' d'_h \rho/\mu$, $v' = v_{super}/(\varepsilon \cos \beta)$, d'_h = channel side width. Particles enhance mass transfer in laminar flow for natural convection. Good fit with correlation of Ray et al., *Intl. J. Heat Mass Transfer,* **41,** 1693 (1998). $N_{Gr} = g \Delta \rho Z^3 \rho/\mu^2$, Z = corrugated plate length. Bubble column results fit correlation of Neme et al., *Chem. Eng. Technol.,* **20,** 297 (1997) for structured packing. N_{St} = Stanton number = kZ/D N_{Fr} = Froude number = v_{super}^2/gz	[48]
T. Liquid fluidized beds	$N_{Sh} = \dfrac{2\xi/\varepsilon^m + \left[\dfrac{(2\xi/\varepsilon^m)(1-\varepsilon)^{1/2}}{[1-(1-\varepsilon)^{1/3}]^2} - 2\right] \tan h\,(\xi/\varepsilon^m)}{\dfrac{\xi/\varepsilon^m}{1-(1-\varepsilon^{1/2})} - \tan h\,(\xi/\varepsilon^m)}$ where $\xi = \left[\dfrac{1}{(1-\varepsilon)^{1/3}} - 1\right] \dfrac{\alpha}{2} N_{Sc}^{1/3} N_{Re}^{1/2}$ This simplifies to: $N_{Sh} = \dfrac{\varepsilon^{1-2m}}{(1-\varepsilon)^{1/3}} \left[\dfrac{1}{(1-\varepsilon)^{1/3}} - 1\right] \dfrac{\alpha^2}{2} N_{Re} N_{Sc}^{2/3}$ $(N_{Re} < 0.1)$	[S] Modification of theory to fit experimental data. For spheres, $m = 1$, $N_{Re} > 2$. $N_{Sh} = \dfrac{k'_L d_p}{D}$, $N_{Re} = \dfrac{V_{super} d_p \xi}{\mu}$ $m = 1$ for $N_{Re} > 2$; $m = 0.5$ for $N_{Re} < 1.0$; ε = voidage; α = const. Best fit data is $\alpha = 0.7$. Comparison of theory and experimental ion exchange results in Ref. 92.	[92] [106] [125]
U. Liquid fluidized beds	$N_{Sh} = 0.250N_{Re}^{0.023}N_{Ga}^{0.306}\left(\dfrac{\rho_s - \rho}{\rho}\right)^{0.282} N_{Sc}^{0.410}$ $(\varepsilon < 0.85)$ $N_{Sh} = 0.304N_{Re}^{-0.057}N_{Ga}^{0.332}\left(\dfrac{\rho_s - \rho}{\rho}\right)^{0.297} N_{Sc}^{0.404}$ $(\varepsilon > 0.85)$ This can be simplified (with slight loss in accuracy at high ε) to $N_{Sh} = 0.245N_{Ga}^{0.323}\left(\dfrac{\rho_s - \rho}{\rho}\right)^{0.300} N_{Sc}^{0.400}$	[E] Correlate amount of data from literature. Predicts very little dependence of N_{Sh} on velocity. Compare large number of published correlations. $N_{Sh} = \dfrac{k'_L d_p}{D}$, $N_{Re} = \dfrac{d_p \rho v_{super}}{\mu}$, $N_{Ga} = \dfrac{d_p^3 \rho^2 g}{\mu^2}$, $N_{Sc} = \dfrac{\mu}{\rho D}$ $1.6 < N_{Re} < 1320$, $2470 < N_{Ga} < 4.42 \times 10^6$ $0.27 < \dfrac{\rho_s - \rho}{\rho} < 1.114$, $305 < N_{Sc} < 1595$	[151]
V. Liquid film flowing over solid particles with air present, trickle bed reactors, fixed bed	$N_{Sh} = \dfrac{k_L}{aD} = 1.8N_{Re}^{1/2}N_{Sc}^{1/3}$, $0.013 < N_{Re} < 12.6$ two-phases, liquid trickle, no forced flow of gas. $N_{Sh} = 0.8N_{Re}^{1/2}N_{Sc}^{1/3}$, one-phase, liquid only.	[E] $N_{Re} = \dfrac{L}{a\mu}$, irregular granules of benzoic acid, $0.29 \le d_p \le 1.45$ cm. L = superficial liquid flow rate, kg/m²s. a = surface area/col. volume, m²/m³.	[130]
W. Supercritical fluids in packed bed	$\dfrac{N_{Sh}}{(N_{Sc}N_{Gr})^{1/4}} = 0.5265 \left(\dfrac{(N_{Re}^{1/2}N_{Sc}^{1/3})}{(N_{Sc}N_{Gr})^{1/4}}\right)^{1.6808} + 2.48 \left\| \left(\dfrac{N_{Re}^2 N_{Sc}^{1/3}}{N_{Gr}}\right)^{0.6439} - 0.8768 \right\|^{1.553}$	[E] Natural and forced convection. $0.3 < N_{Re} < 135$.	[99]
X. Cocurrent gas-liquid flow in fixed beds	Downflow in trickle bed and upflow in bubble columns.	Literature review and meta-analysis. Analyzed both downflow and upflow. Recommendations for best mass- and heat-transfer correlations (see reference).	[95]
Y. Liquid-solid transfer. Electrochemical reaction. Lessing rings. Transfer from liquid to solid	Liquid only: $N_{Sh} = kd/D = 1.57N_{Sc}^{1/3}N_{Re}^{0.46}$ $1390 < N_{Sc} < 4760$, $166 < N_{Re} < 722$ Cocurrent two-phase (liquid and gas) in packed bubble column: $N_{Sh} = 1.93N_{Sc}^{1/3} N_{Re}^{0.34} N_{Re,gas}^{0.11}$ $60 < N_{Re,gas} < 818$, $144 < N_{Re} < 748$	[E] Electrochemical reactors only. d = Lessing ring diameter, $1 < d < 1.4$ cm, $N_{Re} = \rho v_{super} d/\mu$, Deviation ±7% for both cases. $N_{Re,gas} = \rho_{gas} V_{super,gas} d/\mu_{gas}$ Presence of gas enhances mass transfer.	[75]

NOTE: For $N_{Re} < 3$ convective contributions which are not included may become important. Use with logarithmic concentration difference (integrated form) or with arithmetic concentration difference (differential form).
*See the beginning of the "Mass Transfer" subsection for references.

*See the beginning of the "Mass Transfer" subsection for references.

The gas-phase rate coefficient $\hat{k}_G$ is not affected by the fact that a chemical reaction is taking place in the liquid phase. If the liquid-phase chemical reaction is extremely fast and irreversible, the rate of absorption may be governed completely by the resistance to diffusion in the gas phase. In this case the absorption rate may be estimated by knowing only the gas-phase rate coefficient $\hat{k}_G$ or else the height of one gas-phase transfer unit $H_G = G_M/(\hat{k}_G a)$.

It should be noted that the highest possible absorption rates will occur under conditions in which the liquid-phase resistance is negligible and the equilibrium back pressure of the gas over the solvent is zero.

Such situations would exist, for instance, for NH_3 absorption into an acid solution, for SO_2 absorption into an alkali solution, for vaporization of water into air, and for H_2S absorption from a dilute-gas stream into a strong alkali solution, provided there is a large excess of reagent in solution to consume all the dissolved gas. This is known as the gas-phase mass-transfer limited condition, when both the liquid-phase resistance and the back pressure of the gas equal zero. Even when the reaction is sufficiently reversible to allow a small back pressure, the absorption may be gas-phase-controlled, and the values of $\hat{k}_G$ and H_G that would apply to a physical-absorption process will govern the rate.

The liquid-phase rate coefficient $\hat{k}_L$ is strongly affected by fast chemical reactions and generally increases with increasing reaction rate. Indeed, the condition for zero liquid-phase resistance ($m/\hat{k}_L$) implies that either the equilibrium back pressure is negligible, or that $\hat{k}_L$ is very large, or both. Frequently, even though reaction consumes the solute as it is dissolving, thereby enhancing both the mass-transfer coefficient and the driving force for absorption, the reaction rate is slow enough that the liquid-phase resistance must be taken into account. This may be due either to an insufficient supply of a second reagent or to an inherently slow chemical reaction.

In any event the value of $\hat{k}_L$ in the presence of a chemical reaction normally is larger than the value found when only physical absorption occurs, $\hat{k}_L^0$. This has led to the presentation of data on the effects of chemical reaction in terms of the "reaction factor" or "enhancement factor" defined as

$$\phi = \hat{k}_L/\hat{k}_L^0 \geq 1 \tag{5-311}$$

where $\hat{k}_L$ = mass-transfer coefficient with reaction and $\hat{k}_L^0$ = mass-transfer coefficient for pure physical absorption.

It is important to understand that when chemical reactions are involved, this definition of $\hat{k}_L$ is based on the driving force defined as the difference between the concentration of *unreacted* solute gas at the interface and in the bulk of the liquid. A coefficient based on the total of both unreacted and reacted gas could have values *smaller* than the physical-absorption mass-transfer coefficient $\hat{k}_L^0$.

When liquid-phase resistance is important, particular care should be taken in employing any given set of experimental data to ensure that the equilibrium data used conform with those employed by the original author in calculating values of $\hat{k}_L$ or H_L. Extrapolation to widely different concentration ranges or operating conditions should be made with caution, since the mass-transfer coefficient $\hat{k}_L$ may vary in an unexpected fashion, owing to changes in the apparent chemical-reaction mechanism.

Generalized prediction methods for $\hat{k}_L$ and H_L do not apply when chemical reaction occurs in the liquid phase, and therefore one must use actual operating data for the particular system in question. A discussion of the various factors to consider in designing gas absorbers and strippers when chemical reactions are involved is presented by Astarita, Savage, and Bisio, *Gas Treating with Chemical Solvents,* Wiley (1983) and by Kohl and Nielsen, *Gas Purification,* 5th ed., Gulf (1997).

Effective Interfacial Mass-Transfer Area *a* In a packed tower of constant cross-sectional area S the differential change in solute flow per unit time is given by

$$-d(G_M S y) = N_A a\, dV = N_A a S\, dh \tag{5-312}$$

where a = interfacial area effective for mass transfer per unit of packed volume and V = packed volume. Owing to incomplete wetting of the packing surfaces and to the formation of areas of stagnation in the liquid film, the effective area normally is significantly less than the total external area of the packing pieces.

The effective interfacial area depends on a number of factors, as discussed in a review by Charpentier [*Chem. Eng. J.,* **11,** 161 (1976)]. Among these factors are (1) the shape and size of packing, (2) the packing material (for example, plastic generally gives smaller interfacial areas than either metal or ceramic), (3) the liquid mass velocity, and (4), for small-diameter towers, the column diameter.

Whereas the interfacial area generally increases with increasing liquid rate, it apparently is relatively independent of the superficial gas mass velocity below the flooding point. According to Charpentier's review, it appears valid to assume that the interfacial area is independent of the column height when specified in terms of unit packed volume (i.e., as a). Also, the existing data for chemically reacting gas-liquid systems (mostly aqueous electrolyte solutions) indicate that the interfacial area is independent of the chemical system. However, this situation may not hold true for systems involving large heats of reaction.

Rizzuti et al. [*Chem. Eng. Sci.,* **36,** 973 (1981)] examined the influence of solvent viscosity upon the effective interfacial area in packed columns and concluded that for the systems studied the effective interfacial area a was proportional to the kinematic viscosity raised to the 0.7 power. Thus, the hydrodynamic behavior of a packed absorber is strongly affected by viscosity effects. Surface-tension effects also are important, as expressed in the work of Onda et al. (see Table 5-24-C).

In developing correlations for the mass-transfer coefficients $\hat{k}_G$ and $\hat{k}_L$, the various authors have assumed different but internally compatible correlations for the effective interfacial area a. It therefore would be inappropriate to mix the correlations of different authors unless it has been demonstrated that there is a valid area of overlap between them.

Volumetric Mass-Transfer Coefficients $\hat{K}_G a$ and $\hat{K}_L a$ Experimental determinations of the individual mass-transfer coefficients $\hat{k}_G$ and $\hat{k}_L$ and of the effective interfacial area a involve the use of extremely difficult techniques, and therefore such data are not plentiful. More often, column experimental data are reported in terms of overall volumetric coefficients, which normally are defined as follows:

$$K'_G a = n_A/(h_T S p_T \Delta y^\circ_{1m}) \tag{5-313}$$

and

$$K_L a = n_A/(h_T S\, \Delta x^\circ_{1m}) \tag{5-314}$$

where $K'_G a$ = overall volumetric gas-phase mass-transfer coefficient, $K_L a$ = overall volumetric liquid-phase mass-transfer coefficient, n_A = overall rate of transfer of solute A, h_T = total packed depth in tower, S = tower cross-sectional area, p_T = total system pressure employed during the experiment, and Δx°_{1m} and Δy°_{1m} are defined as

$$\Delta y^\circ_{1m} = \frac{(y - y^\circ)_1 - (y - y^\circ)_2}{\ln\,[(y - y^\circ)_1/(y - y^\circ)_2]} \tag{5-315}$$

and

$$\Delta x^\circ_{1m} = \frac{(x^\circ - x)_2 - (x^\circ - x)_1}{\ln\,[(x^\circ - x)_2/(x^\circ - x)_1]} \tag{5-316}$$

where subscripts 1 and 2 refer to the bottom and top of the tower respectively.

Experimental $K'_G a$ and $K_L a$ data are available for most absorption and stripping operations of commercial interest (see Sec. 14). The solute concentrations employed in these experiments normally are very low, so that $K_L a \doteq \hat{K}_L a$ and $K'_G a p_T \doteq \hat{K}_G a$, where p_T is the total pressure employed in the actual experimental-test system. Unlike the individual gas-film coefficient $\hat{k}_G a$, the overall coefficient $\hat{K}_G a$ will vary with the total system pressure except when the liquid-phase resistance is negligible (i.e., when either $m = 0$, or $\hat{k}_L a$ is very large, or both).

Extrapolation of $K_G a$ data for absorption and stripping to conditions other than those for which the original measurements were made can be extremely risky, especially in systems involving chemical reactions in the liquid phase. One therefore would be wise to restrict the use of overall volumetric mass-transfer-coefficient data to conditions not too far removed from those employed in the actual tests. The most reliable data for this purpose would be those obtained from an operating commercial unit of similar design.

Experimental values of H_{OG} and H_{OL} for a number of distillation systems of commercial interest are also readily available. Extrapolation of the data or the correlations to conditions that differ significantly from those used for the original experiments is risky. For example, pressure has a major effect on vapor density and thus can affect the hydrodynamics significantly. Changes in flow patterns affect both mass-transfer coefficients and interfacial area.

Chilton-Colburn Analogy On occasion one will find that heat-transfer-rate data are available for a system in which mass-transfer-rate data are not readily available. The Chilton-Colburn analogy [90, 53] (see Tables 5-17-G and 5-19-T) provides a procedure for developing estimates of the mass-transfer rates based on heat-transfer data. Extrapolation of experimental j_M or j_H data obtained with gases to predict liquid systems (and vice versa) should be approached with caution, however. When pressure-drop or friction-factor data are available, one may be able to place an upper bound on the rates of heat and mass transfer of $f/2$. The Chilton-Colburn analogy can be used for simultaneous heat and mass transfer as long as the concentration and temperature fields are independent [Venkatesan and Fogler, *AIChE J.* **50,** 1623 (2004)].

NATURE OF FLUIDS

Deformation and Stress A **fluid** is a substance which undergoes continuous deformation when subjected to a shear stress. Figure 6-1 illustrates this concept. A fluid is bounded by two large parallel plates, of area A, separated by a small distance H. The bottom plate is held fixed. Application of a force F to the upper plate causes it to move at a velocity U. The fluid continues to deform as long as the force is applied, unlike a solid, which would undergo only a finite deformation.

The force is directly proportional to the area of the plate; the shear stress is $\tau = F/A$. Within the fluid, a linear velocity profile $u = Uy/H$ is established; due to the **no-slip condition,** the fluid bounding the lower plate has zero velocity and the fluid bounding the upper plate moves at the plate velocity U. The velocity gradient $\dot{\gamma} = du/dy$ is called the **shear rate** for this flow. Shear rates are usually reported in units of reciprocal seconds. The flow in Fig. 6-1 is a **simple shear flow.**

Viscosity The ratio of shear stress to shear rate is the viscosity, μ.

$$\mu = \frac{\tau}{\dot{\gamma}} \tag{6-1}$$

The SI units of viscosity are kg/(m · s) or Pa · s (pascal second). The cgs unit for viscosity is the poise; 1 Pa · s equals 10 poise or 1000 centipoise (cP) or 0.672 lbm/(ft · s). The terms *absolute viscosity* and *shear viscosity* are synonymous with the viscosity as used in Eq. (6-1). **Kinematic viscosity** $\nu \equiv \mu/\rho$ is the ratio of viscosity to density. The SI units of kinematic viscosity are m^2/s. The cgs stoke is 1 cm^2/s.

Rheology In general, fluid flow patterns are more complex than the one shown in Fig. 6-1, as is the relationship between fluid deformation and stress. Rheology is the discipline of fluid mechanics which studies this relationship. One goal of rheology is to obtain **constitutive equations** by which stresses may be computed from deformation rates. For simplicity, fluids may be classified into rheological types in reference to the simple shear flow of Fig. 6-1. Complete definitions require extension to multidimensional flow. For more information, several good references are available, including Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977); Metzner ("Flow of Non-Newtonian Fluids" in Streeter, *Handbook of Fluid Dynamics,* McGraw-Hill, New York, 1971); and Skelland (*Non-Newtonian Flow and Heat Transfer*, Wiley, New York, 1967).

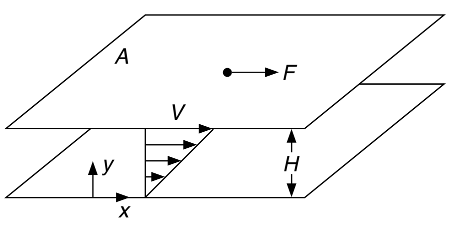

FIG. 6-1 Deformation of a fluid subjected to a shear stress.

Fluids without any solidlike elastic behavior do not undergo any reverse deformation when shear stress is removed, and are called **purely viscous** fluids. The shear stress depends only on the rate of deformation, and not on the extent of deformation (strain). Those which exhibit both viscous and elastic properties are called **viscoelastic** fluids.

Purely viscous fluids are further classified into time-independent and time-dependent fluids. For time-independent fluids, the shear stress depends only on the instantaneous shear rate. The shear stress for time-dependent fluids depends on the past history of the rate of deformation, as a result of structure or orientation buildup or breakdown during deformation.

A **rheogram** is a plot of shear stress versus shear rate for a fluid in simple shear flow, such as that in Fig. 6-1. Rheograms for several types of time-independent fluids are shown in Fig. 6-2. The **Newtonian** fluid rheogram is a straight line passing through the origin. The slope of the line is the viscosity. For a Newtonian fluid, the viscosity is independent of shear rate, and may depend only on temperature and perhaps pressure. By far, the Newtonian fluid is the largest class of fluid of engineering importance. Gases and low molecular weight liquids are generally Newtonian. Newton's law of viscosity is a rearrangement of Eq. (6-1) in which the viscosity is a constant:

$$\tau = \mu\dot{\gamma} = \mu \frac{du}{dy} \tag{6-2}$$

All fluids for which the viscosity varies with shear rate are **non-Newtonian fluids.** For non-Newtonian fluids the viscosity, defined as the ratio of shear stress to shear rate, is often called the **apparent viscosity** to emphasize the distinction from Newtonian behavior. Purely viscous, time-independent fluids, for which the apparent viscosity may be expressed as a function of shear rate, are called **generalized Newtonian fluids.**

Non-Newtonian fluids include those for which a finite stress τ_y is required before continuous deformation occurs; these are called **yield-stress** materials. The **Bingham plastic** fluid is the simplest yield-stress material; its rheogram has a constant slope μ_∞, called the *infinite shear* viscosity.

$$\tau = \tau_y + \mu_\infty\dot{\gamma} \tag{6-3}$$

Highly concentrated suspensions of fine solid particles frequently exhibit Bingham plastic behavior.

Shear-thinning fluids are those for which the slope of the rheogram decreases with increasing shear rate. These fluids have also been called *pseudoplastic,* but this terminology is outdated and discouraged. Many polymer melts and solutions, as well as some solids suspensions, are shear-thinning. Shear-thinning fluids without yield stresses typically obey a power law model over a range of shear rates.

$$\tau = K\dot{\gamma}^n \tag{6-4}$$

The apparent viscosity is

$$\mu = K\dot{\gamma}^{n-1} \tag{6-5}$$

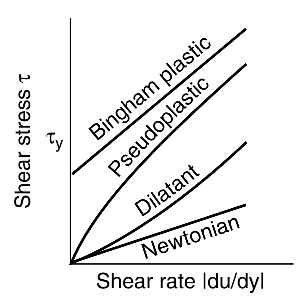

FIG. 6-2 Shear diagrams.

The factor K is the consistency index or power law coefficient, and n is the power law exponent. The exponent n is dimensionless, while K is in units of $kg/(m \cdot s^{2-n})$. For shear-thinning fluids, $n < 1$. The power law model typically provides a good fit to data over a range of one to two orders of magnitude in shear rate; behavior at very low and very high shear rates is often Newtonian. Shear-thinning power law fluids with yield stresses are sometimes called *Herschel-Bulkley fluids.* Numerous other rheological model equations for shear-thinning fluids are in common use.

Dilatant, or shear-thickening, fluids show increasing viscosity with increasing shear rate. Over a limited range of shear rate, they may be described by the power law model with $n > 1$. Dilatancy is rare, observed only in certain concentration ranges in some particle suspensions (Govier and Aziz, pp. 33–34). Extensive discussions of dilatant suspensions, together with a listing of dilatant systems, are given by Green and Griskey (*Trans. Soc. Rheol,* **12**[1], 13–25 [1968]); Griskey and Green (*AIChE J.,* **17,** 725–728 [1971]); and Bauer and Collins ("Thixotropy and Dilatancy," in Eirich, *Rheology,* vol. 4, Academic, New York, 1967).

Time-dependent fluids are those for which structural rearrangements occur during deformation at a rate too slow to maintain equilibrium configurations. As a result, shear stress changes with duration of shear. **Thixotropic** fluids, such as mayonnaise, clay suspensions used as drilling muds, and some paints and inks, show decreasing shear stress with time at constant shear rate. A detailed description of thixotropic behavior and a list of thixotropic systems is found in Bauer and Collins (ibid.).

Rheopectic behavior is the opposite of thixotropy. Shear stress increases with time at constant shear rate. Rheopectic behavior has been observed in bentonite sols, vanadium pentoxide sols, and gypsum suspensions in water (Bauer and Collins, ibid.) as well as in some polyester solutions (Steg and Katz, *J. Appl. Polym. Sci.,* **9,** 3, 177 [1965]).

Viscoelastic fluids exhibit elastic recovery from deformation when stress is removed. Polymeric liquids comprise the largest group of fluids in this class. A property of viscoelastic fluids is the *relaxation time,* which is a measure of the time required for elastic effects to decay. Viscoelastic effects may be important with sudden changes in rates of deformation, as in flow startup and stop, rapidly oscillating flows, or as a fluid passes through sudden expansions or contractions where accelerations occur. In many fully developed flows where such effects are absent, viscoelastic fluids behave as if they were purely viscous. In viscoelastic flows, normal stresses perpendicular to the direction of shear are different from those in the parallel direction. These give rise to such behaviors as the *Weissenberg effect,* in which fluid climbs up a shaft rotating in the fluid, and *die swell,* where a stream of fluid issuing from a tube may expand to two or more times the tube diameter.

A parameter indicating whether viscoelastic effects are important is the **Deborah number,** which is the ratio of the characteristic relaxation time of the fluid to the characteristic time scale of the flow. For small Deborah numbers, the relaxation is fast compared to the characteristic time of the flow, and the fluid behavior is purely viscous. For very large Deborah numbers, the behavior closely resembles that of an elastic solid.

Analysis of viscoelastic flows is very difficult. Simple constitutive equations are unable to describe all the material behavior exhibited by viscoelastic fluids even in geometrically simple flows. More complex constitutive equations may be more accurate, but become exceedingly difficult to apply, especially for complex geometries, even with advanced numerical methods. For good discussions of viscoelastic fluid behavior, including various types of constitutive equations, see Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* vol. 2: *Kinetic Theory,* Wiley, New York, 1977); Middleman (*The Flow of High Polymers,* Interscience (Wiley) New York, 1968); or Astarita and Marrucci (*Principles of Non-Newtonian Fluid Mechanics,* McGraw-Hill, New York, 1974).

Polymer processing is the field which depends most on the flow of non-Newtonian fluids. Several excellent texts are available, including Middleman (*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977) and Tadmor and Gogos (*Principles of Polymer Processing,* Wiley, New York, 1979).

There is a wide variety of instruments for measurement of Newtonian viscosity, as well as rheological properties of non-Newtonian fluids. They are described in Van Wazer, Lyons, Kim, and Colwell (*Viscosity and Flow Measurement,* Interscience, New York, 1963); Coleman, Markowitz, and Noll (*Viscometric Flows of Non-Newtonian Fluids,* Springer-Verlag, Berlin, 1966); Dealy and Wissbrun (*Melt Rheology and Its Role in Plastics Processing,* Van Nostrand Reinhold, 1990). Measurement of rheological behavior requires well-characterized flows. Such *rheometric* flows are thoroughly discussed by Astarita and Marrucci (*Principles of Non-Newtonian Fluid Mechanics,* McGraw-Hill, New York, 1974).

KINEMATICS OF FLUID FLOW

Velocity The term *kinematics* refers to the quantitative description of fluid motion or deformation. The rate of deformation depends on the distribution of velocity within the fluid. Fluid velocity **v** is a vector quantity, with three cartesian components v_x, v_y, and v_z. The velocity vector is a function of spatial position and time. A **steady** flow is one in which the velocity is independent of time, while in **unsteady** flow **v** varies with time**.**

Compressible and Incompressible Flow An incompressible flow is one in which the density of the fluid is constant or nearly constant. Liquid flows are normally treated as incompressible, except in the context of hydraulic transients (see following). Compressible fluids, such as gases, may undergo incompressible flow if pressure and/or temperature changes are small enough to render density changes insignificant. Frequently, compressible flows are regarded as flows in which the density varies by more than 5 to 10 percent.

Streamlines, Pathlines, and Streaklines These are curves in a flow field which provide insight into the flow pattern. *Streamlines* are tangent at every point to the local instantaneous velocity vector. A *pathline* is the path followed by a material element of fluid; it coincides with a streamline if the flow is steady. In unsteady flow the pathlines generally do not coincide with streamlines. *Streaklines* are curves on which are found all the material particles which passed through a particular point in space at some earlier time. For example, a streakline is revealed by releasing smoke or dye at a point in a flow field. For steady flows, streamlines, pathlines, and streaklines are indistinguishable. In two-dimensional incompressible flows, streamlines are contours of the **stream function.**

One-dimensional Flow Many flows of great practical importance, such as those in pipes and channels, are treated as one-dimensional flows. There is a single direction called the *flow direction;* velocity components perpendicular to this direction are either zero or considered unimportant. Variations of quantities such as velocity, pressure, density, and temperature are considered only in the flow direction. The fundamental conservation equations of fluid mechanics are greatly simplified for one-dimensional flows. A broader category of one-dimensional flow is one where there is only one nonzero velocity component, which depends on only one coordinate direction, and this coordinate direction may or may not be the same as the flow direction.

Rate of Deformation Tensor For general three-dimensional flows, where all three velocity components may be important and may vary in all three coordinate directions, the concept of deformation previously introduced must be generalized. The rate of deformation tensor D_{ij} has nine components. In Cartesian coordinates,

$$D_{ij} = \left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right) \tag{6-6}$$

where the subscripts i and j refer to the three coordinate directions. Some authors define the deformation rate tensor as one-half of that given by Eq. (6-6).

Vorticity The relative motion between two points in a fluid can be decomposed into three components: rotation, dilatation, and deformation. The rate of deformation tensor has been defined. Dilatation refers to the volumetric expansion or compression of the fluid, and vanishes for incompressible flow. Rotation is described by a tensor $\omega_{ij} = \partial v_i/\partial x_j - \partial v_j/\partial x_i$. The vector of vorticity given by one-half the

curl of the velocity vector is another measure of rotation. In two-dimensional flow in the *x-y* plane, the vorticity ω is given by

$$\omega = \frac{1}{2}\left(\frac{\partial v_y}{\partial x} - \frac{\partial v_x}{\partial y}\right) \tag{6-7}$$

Here ω is the magnitude of the vorticity vector, which is directed along the *z* axis. An **irrotational** flow is one with zero vorticity. Irrotational flows have been widely studied because of their useful mathematical properties and applicability to flow regions where viscous effects may be neglected. Such flows without viscous effects are called **inviscid** flows.

Laminar and Turbulent Flow, Reynolds Number These terms refer to two distinct types of flow. In *laminar flow,* there are smooth streamlines and the fluid velocity components vary smoothly with position, and with time if the flow is unsteady. The flow described in reference to Fig. 6-1 is laminar. In *turbulent flow,* there are no smooth streamlines, and the velocity shows chaotic fluctuations in time and space. Velocities in turbulent flow may be reported as the sum of a time-averaged velocity and a velocity fluctuation from the average. For any given flow geometry, a dimensionless **Reynolds number** may be defined for a Newtonian fluid as $\mathrm{Re} = LU\rho/\mu$ where L is a characteristic length. Below a critical value of Re the flow is laminar, while above the critical value a transition to turbulent flow occurs. The geometry-dependent critical Reynolds number is determined experimentally.

CONSERVATION EQUATIONS

Macroscopic and Microscopic Balances Three postulates, regarded as laws of physics, are fundamental in fluid mechanics. These are *conservation of mass, conservation of momentum,* and *conservation of energy.* In addition, two other postulates, *conservation of moment of momentum* (angular momentum) and the *entropy inequality* (second law of thermodynamics) have occasional use. The conservation principles may be applied either to material systems or to control volumes in space. Most often, control volumes are used. The control volumes may be either of finite or differential size, resulting in either **algebraic** or **differential** conservation equations, respectively. These are often called **macroscopic** and **microscopic** balance equations.

Macroscopic Equations An arbitrary control volume of finite size V_a is bounded by a surface of area A_a with an outwardly directed unit normal vector **n.** The control volume is not necessarily fixed in space. Its boundary moves with velocity **w.** The fluid velocity is **v.** Figure 6-3 shows the arbitrary control volume.

Mass Balance Applied to the control volume, the principle of conservation of mass may be written as (Whitaker, *Introduction to Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1968, Krieger, Huntington, N.Y., 1981)

$$\frac{d}{dt}\int_{V_a} \rho\, dV + \int_{A_a} \rho(\mathbf{v} - \mathbf{w})\cdot \mathbf{n}\, dA = 0 \tag{6-8}$$

This equation is also known as the **continuity** equation.

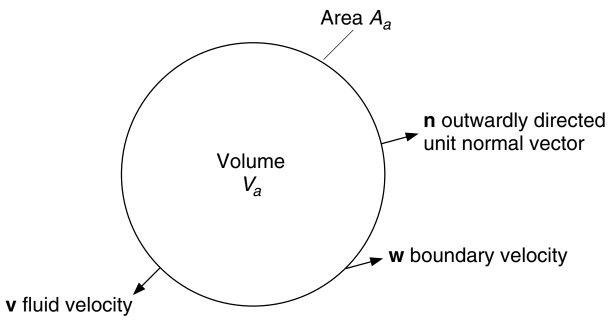

FIG. 6-3 Arbitrary control volume for application of conservation equations.

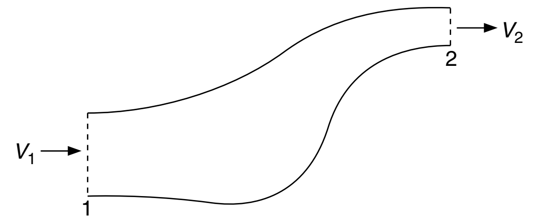

FIG. 6-4 Fixed control volume with one inlet and one outlet.

Simplified forms of Eq. (6-8) apply to special cases frequently found in practice. For a control volume fixed in space with one inlet of area A_1 through which an incompressible fluid enters the control volume at an average velocity V_1, and one outlet of area A_2 through which fluid leaves at an average velocity V_2, as shown in Fig. 6-4, the continuity equation becomes

$$V_1A_1 = V_2A_2 \tag{6-9}$$

The average velocity across a surface is given by

$$V = (1/A)\int_A v\, dA$$

where v is the local velocity component perpendicular to the inlet surface. The volumetric flow rate Q is the product of average velocity and the cross-sectional area, $Q = VA$. The average **mass velocity** is $G = \rho V$. For steady flows through fixed control volumes with multiple inlets and/or outlets, conservation of mass requires that the sum of inlet mass flow rates equals the sum of outlet mass flow rates. For incompressible flows through fixed control volumes, the sum of inlet flow rates (mass or volumetric) equals the sum of exit flow rates, whether the flow is steady or unsteady.

Momentum Balance Since momentum is a vector quantity, the momentum balance is a vector equation. Where gravity is the only body force acting on the fluid, the linear momentum principle, applied to the arbitrary control volume of Fig. 6-3, results in the following expression (Whitaker, ibid.).

$$\frac{d}{dt}\int_{V_a} \rho\mathbf{v}\, dV + \int_{A_a} \rho\mathbf{v}(\mathbf{v} - \mathbf{w})\cdot\mathbf{n}\, dA = \int_{V_a} \rho\mathbf{g}\, dV + \int_{A_a} \mathbf{t_n}\, dA \tag{6-10}$$

Here **g** is the gravity vector and $\mathbf{t_n}$ is the force per unit area exerted by the surroundings on the fluid in the control volume. The integrand of the area integral on the left-hand side of Eq. (6-10) is nonzero only on the entrance and exit portions of the control volume boundary. For the special case of steady flow at a mass flow rate $\dot{m}$ through a control volume fixed in space with one inlet and one outlet (Fig. 6-4), with the inlet and outlet velocity vectors perpendicular to planar inlet and outlet surfaces, giving average velocity vectors $\mathbf{V}_1$ and $\mathbf{V}_2$, the momentum equation becomes

$$\dot{m}(\beta_2\mathbf{V}_2 - \beta_1\mathbf{V}_1) = -p_1\mathbf{A}_1 - p_2\mathbf{A}_2 + \mathbf{F} + M\mathbf{g} \tag{6-11}$$

where M is the total mass of fluid in the control volume. The factor β arises from the averaging of the velocity across the area of the inlet or outlet surface. It is the ratio of the area average of the square of velocity magnitude to the square of the area average velocity magnitude. For a uniform velocity, β = 1. For turbulent flow, β is nearly unity, while for laminar pipe flow with a parabolic velocity profile, β = 4/3. The vectors $\mathbf{A}_1$ and $\mathbf{A}_2$ have magnitude equal to the areas of the inlet and outlet surfaces, respectively, and are outwardly directed normal to the surfaces. The vector **F** is the force exerted on the fluid by the nonflow boundaries of the control volume. It is also assumed that the stress vector $\mathbf{t_n}$ is normal to the inlet and outlet surfaces, and that its magnitude may be approximated by the pressure p. Equation (6-11) may be generalized to multiple inlets and/or outlets. In such cases, the mass flow rates for all the inlets and outlets are not equal. A distinct flow rate $\dot{m}_i$ applies to each inlet or outlet *i*. To generalize the equation, $-p\mathbf{A}$ terms for each inlet and outlet, $-\dot{m}\beta\mathbf{V}$ terms for each inlet, and $\dot{m}\beta\mathbf{V}$ terms for each outlet are included.

Balance equations for angular momentum, or moment of momentum, may also be written. They are used less frequently than the linear momentum equations. See Whitaker (*Introduction to Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1968, Krieger, Huntington, N.Y., 1981) or Shames (*Mechanics of Fluids,* 3d ed., McGraw-Hill, New York, 1992).

Total Energy Balance The total energy balance derives from the first law of thermodynamics. Applied to the arbitrary control volume of Fig. 6-3, it leads to an equation for the rate of change of the sum of internal, kinetic, and gravitational potential energy. In this equation, u is the internal energy per unit mass, v is the magnitude of the velocity vector **v,** z is elevation, g is the gravitational acceleration, and **q** is the heat flux vector:

$$\frac{d}{dt}\int_{V_a}\rho\left(u+\frac{v^2}{2}+gz\right)dV+\int_{A_a}\rho\left(u+\frac{v^2}{2}+gz\right)(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\,dA$$
$$=\int_{A_a}(\mathbf{v}\cdot\mathbf{t_n})\,dA-\int_{A_a}(\mathbf{q}\cdot\mathbf{n})\,dA \qquad (6\text{-}12)$$

The first integral on the right-hand side is the rate of work done on the fluid in the control volume by forces at the boundary. It includes both work done by moving solid boundaries and work done at flow entrances and exits. The work done by moving solid boundaries also includes that by such surfaces as pump impellers; this work is called **shaft work;** its rate is $\dot{W}_S$.

A useful simplification of the total energy equation applies to a particular set of assumptions. These are a control volume with fixed solid boundaries, except for those producing shaft work, steady state conditions, and mass flow at a rate $\dot{m}$ through a single planar entrance and a single planar exit (Fig. 6-4), to which the velocity vectors are perpendicular. As with Eq. (6-11), it is assumed that the stress vector $\mathbf{t_n}$ is normal to the entrance and exit surfaces and may be approximated by the pressure p. The **equivalent pressure,** $p+\rho gz$, is assumed to be uniform across the entrance and exit. The average velocity at the entrance and exit surfaces is denoted by V. Subscripts 1 and 2 denote the entrance and exit, respectively.

$$h_1+\alpha_1\frac{V_1^2}{2}+gz_1=h_2+\alpha_2\frac{V_2^2}{2}+gz_2-\delta Q-\delta W_S \qquad (6\text{-}13)$$

Here, h is the enthalpy per unit mass, $h=u+p/\rho$. The shaft work per unit of mass flowing through the control volume is $\delta W_S=\dot{W}_s/\dot{m}$. Similarly, δQ is the heat input per unit of mass. The factor α is the ratio of the cross-sectional area average of the cube of the velocity to the cube of the average velocity. For a uniform velocity profile, $\alpha=1$. In turbulent flow, α is usually assumed to equal unity; in turbulent pipe flow, it is typically about 1.07. For laminar flow in a circular pipe with a parabolic velocity profile, $\alpha=2$.

Mechanical Energy Balance, Bernoulli Equation A balance equation for the sum of kinetic and potential energy may be obtained from the momentum balance by forming the scalar product with the velocity vector. The resulting equation, called the *mechanical energy balance,* contains a term accounting for the dissipation of mechanical energy into thermal energy by viscous forces. The mechanical energy equation is also derivable from the total energy equation in a way that reveals the relationship between the dissipation and entropy generation. The macroscopic mechanical energy balance for the arbitrary control volume of Fig. 6-3 may be written, with p = thermodynamic pressure, as

$$\frac{d}{dt}\int_{V_a}\rho\left(\frac{v^2}{2}+gz\right)dV+\int_{A_a}\rho\left(\frac{v^2}{2}+gz\right)(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\,dA$$
$$=\int_{V_a}p\,\boldsymbol{\nabla}\cdot\mathbf{v}\,dV+\int_{A_a}(\mathbf{v}\cdot\mathbf{t}_n)\,dA-\int_{V_a}\Phi\,dV \qquad (6\text{-}14)$$

The last term is the rate of viscous energy dissipation to internal energy, $\dot{E}_v=\int_{V_a}\Phi\,dV$, also called the rate of viscous losses. These losses are the origin of frictional pressure drop in fluid flow. Whitaker and Bird, Stewart, and Lightfoot provide expressions for the dissipation function Φ for Newtonian fluids in terms of the local velocity gradients. However, when using macroscopic balance equations the local velocity field within the control volume is usually unknown. For such cases additional information, which may come from empirical correlations, is needed.

For the same special conditions as for Eq. (6-13), the mechanical energy equation is reduced to

$$\alpha_1\frac{V_1^2}{2}+gz_1+\delta W_S=\alpha_2\frac{V_2^2}{2}+gz_2+\int_{p_1}^{p_2}\frac{dp}{\rho}+l_v \qquad (6\text{-}15)$$

Here $l_v=\dot{E}_v/\dot{m}$ is the energy dissipation per unit mass. This equation has been called the **engineering Bernoulli equation.** For an incompressible flow, Eq. (6-15) becomes

$$\frac{p_1}{\rho}+\alpha_1\frac{V_1^2}{2}+gz_1+\delta W_S=\frac{p_2}{\rho}+\alpha_2\frac{V_2^2}{2}+gz_2+l_v \qquad (6\text{-}16)$$

The Bernoulli equation can be written for incompressible, inviscid flow along a streamline, where no shaft work is done.

$$\frac{p_1}{\rho}+\frac{V_1^2}{2}+gz_1=\frac{p_2}{\rho}+\frac{V_2^2}{2}+gz_2 \qquad (6\text{-}17)$$

Unlike the momentum equation (Eq. [6-11]), the Bernoulli equation is not easily generalized to multiple inlets or outlets.

Microscopic Balance Equations Partial differential balance equations express the conservation principles at a point in space. Equations for mass, momentum, total energy, and mechanical energy may be found in Whitaker (ibid.), Bird, Stewart, and Lightfoot (*Transport Phenomena,* Wiley, New York, 1960), and Slattery (*Momentum, Heat and Mass Transfer in Continua,* 2d ed., Krieger, Huntington, N.Y., 1981), for example. These references also present the equations in other useful coordinate systems besides the cartesian system. The coordinate systems are fixed in inertial reference frames. The two most used equations, for mass and momentum, are presented here.

Mass Balance, Continuity Equation The continuity equation, expressing conservation of mass, is written in cartesian coordinates as

$$\frac{\partial\rho}{\partial t}+\frac{\partial\rho v_x}{\partial x}+\frac{\partial\rho v_y}{\partial y}+\frac{\partial\rho v_z}{\partial z}=0 \qquad (6\text{-}18)$$

In terms of the **substantial derivative,** D/Dt,

$$\frac{D\rho}{Dt}\equiv\frac{\partial\rho}{\partial t}+v_x\frac{\partial\rho}{\partial x}+v_y\frac{\partial\rho}{\partial y}+v_z\frac{\partial\rho}{\partial z}=-\rho\left(\frac{\partial v_x}{\partial x}+\frac{\partial v_y}{\partial y}+\frac{\partial v_z}{\partial z}\right) \qquad (6\text{-}19)$$

The substantial derivative, also called the **material derivative,** is the rate of change in a Lagrangian reference frame, that is, following a material particle. In vector notation the continuity equation may be expressed as

$$\frac{D\rho}{Dt}=-\rho\nabla\cdot\mathbf{v} \qquad (6\text{-}20)$$

For incompressible flow,

$$\nabla\cdot\mathbf{v}=\frac{\partial v_x}{\partial x}+\frac{\partial v_y}{\partial y}+\frac{\partial v_z}{\partial z}=0 \qquad (6\text{-}21)$$

Stress Tensor The stress tensor is needed to completely describe the stress state for microscopic momentum balances in multidimensional flows. The components of the stress tensor σ_{ij} give the force in the j direction on a plane perpendicular to the i direction, using a sign convention defining a positive stress as one where the fluid with the greater i coordinate value exerts a force in the positive i direction on the fluid with the lesser i coordinate. Several references in fluid mechanics and continuum mechanics provide discussions, to various levels of detail, of stress in a fluid (Denn; Bird, Stewart, and Lightfoot; Schlichting; Fung [*A First Course in Continuum Mechanics,* 2d. ed., Prentice-Hall, Englewood Cliffs, N.J., 1977]; Truesdell and Toupin [in Flügge, *Handbuch der Physik,* vol. 3/1, Springer-Verlag, Berlin, 1960]; Slattery [*Momentum, Energy and Mass Transfer in Continua,* 2d ed., Krieger, Huntington, N.Y., 1981]).

The stress has an isotropic contribution due to fluid pressure and dilatation, and a **deviatoric** contribution due to viscous deformation effects. The deviatoric contribution for a Newtonian fluid is the three-dimensional generalization of Eq. (6-2):

$$\tau_{ij}=\mu D_{ij} \qquad (6\text{-}22)$$

The total stress is

$$\sigma_{ij} = (-p + \lambda\nabla \cdot \mathbf{v})\delta_{ij} + \tau_{ij} \tag{6-23}$$

The identity tensor δ_{ij} is zero for $i \neq j$ and unity for $i = j$. The coefficient λ is a material property related to the **bulk viscosity,** $\kappa = \lambda + 2\mu/3$. There is considerable uncertainty about the value of κ. Traditionally, Stokes' hypothesis, $\kappa = 0$, has been invoked, but the validity of this hypothesis is doubtful (Slattery, ibid.). For incompressible flow, the value of bulk viscosity is immaterial as Eq. (6-23) reduces to

$$\sigma_{ij} = -p\delta_{ij} + \tau_{ij} \tag{6-24}$$

Similar generalizations to multidimensional flow are necessary for non-Newtonian constitutive equations.

Cauchy Momentum and Navier-Stokes Equations The differential equations for conservation of momentum are called the **Cauchy momentum equations.** These may be found in general form in most fluid mechanics texts (e.g., Slattery [ibid.]; Denn; Whitaker; and Schlichting). For the important special case of an incompressible Newtonian fluid with constant viscosity, substitution of Eqs. (6-22) and (6-24) leads to the **Navier-Stokes equations,** whose three Cartesian components are

$$\rho\left(\frac{\partial v_x}{\partial t} + v_x\frac{\partial v_x}{\partial x} + v_y\frac{\partial v_x}{\partial y} + v_z\frac{\partial v_x}{\partial z}\right) = -\frac{\partial p}{\partial x} + \mu\left(\frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_x}{\partial y^2} + \frac{\partial^2 v_x}{\partial z^2}\right) + \rho g_x \tag{6-25}$$

$$\rho\left(\frac{\partial v_y}{\partial t} + v_x\frac{\partial v_y}{\partial x} + v_y\frac{\partial v_y}{\partial y} + v_z\frac{\partial v_y}{\partial z}\right) = -\frac{\partial p}{\partial y} + \mu\left(\frac{\partial^2 v_y}{\partial x^2} + \frac{\partial^2 v_y}{\partial y^2} + \frac{\partial^2 v_y}{\partial z^2}\right) + \rho g_y \tag{6-26}$$

$$\rho\left(\frac{\partial v_z}{\partial t} + v_x\frac{\partial v_z}{\partial x} + v_y\frac{\partial v_z}{\partial y} + v_z\frac{\partial v_z}{\partial z}\right) = -\frac{\partial p}{\partial z} + \mu\left(\frac{\partial^2 v_z}{\partial x^2} + \frac{\partial^2 v_z}{\partial y^2} + \frac{\partial^2 v_z}{\partial z^2}\right) + \rho g_z \tag{6-27}$$

In vector notation,

$$\rho\frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{v} = -\nabla p + \mu\nabla^2\mathbf{v} + \rho\mathbf{g} \tag{6-28}$$

The pressure and gravity terms may be combined by replacing the pressure p by the equivalent pressure $P = p + \rho gz$. The left-hand side terms of the Navier-Stokes equations are the **inertial terms,** while the terms including viscosity μ are the **viscous terms.** Limiting cases under which the Navier-Stokes equations may be simplified include **creeping flows** in which the inertial terms are neglected, **potential flows** (inviscid or irrotational flows) in which the viscous terms are neglected, and **boundary layer** and **lubrication** flows in which certain terms are neglected based on scaling arguments. Creeping flows are described by Happel and Brenner (*Low Reynolds Number Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1965); potential flows by Lamb (*Hydrodynamics,* 6th ed., Dover, New York, 1945) and Milne-Thompson (*Theoretical Hydrodynamics,* 5th ed., Macmillan, New York, 1968); boundary layer theory by Schlichting (*Boundary Layer Theory,* 8th ed., McGraw-Hill, New York, 1987); and lubrication theory by Batchelor (*An Introduction to Fluid Dynamics,* Cambridge University, Cambridge, 1967) and Denn (*Process Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1980).

Because the Navier-Stokes equations are first-order in pressure and second-order in velocity, their solution requires one pressure boundary condition and two velocity boundary conditions (for each velocity component) to completely specify the solution. The **no slip** condition, which requires that the fluid velocity equal the velocity of any bounding solid surface, occurs in most problems. Specification of velocity is a type of boundary condition sometimes called a *Dirichlet condition.* Often boundary conditions involve stresses, and thus velocity gradients, rather than the velocities themselves. Specification of velocity derivatives is a *Neumann boundary condition.* For example, at the boundary between a viscous liquid and a gas, it is often assumed that the liquid shear stresses are zero. In numerical solution of the Navier-Stokes equations, Dirichlet and Neumann, or **essential** and **natural,** boundary conditions may be satisfied by different means.

Fluid statics, discussed in Sec. 10 of the *Handbook* in reference to pressure measurement, is the branch of fluid mechanics in which the fluid velocity is either zero or is uniform and constant relative to an inertial reference frame. With velocity gradients equal to zero, the momentum equation reduces to a simple expression for the pressure field, $\nabla p = \rho\mathbf{g}$. Letting z be directed vertically upward, so that $g_z = -g$ where g is the gravitational acceleration (9.806 m^2/s), the pressure field is given by

$$dp/dz = -\rho g \tag{6-29}$$

This equation applies to any incompressible or compressible static fluid. For an incompressible liquid, pressure varies linearly with depth. For compressible gases, p is obtained by integration accounting for the variation of ρ with z.

The **force exerted on a submerged planar surface** of area A is given by $F = p_cA$ where p_c is the pressure at the geometrical **centroid** of the surface. The **center of pressure,** the point of application of the net force, is always lower than the centroid. For details see, for example, Shames, where may also be found discussion of forces on **curved surfaces, buoyancy,** and **stability of floating bodies.**

Examples Four examples follow, illustrating the application of the conservation equations to obtain useful information about fluid flows.

Example 1: Force Exerted on a Reducing Bend An incompressible fluid flows through a reducing elbow (Fig. 6-5) situated in a horizontal plane. The inlet velocity V_1 is given and the pressures p_1 and p_2 are measured. Selecting the inlet and outlet surfaces 1 and 2 as shown, the continuity equation Eq. (6-9) can be used to find the exit velocity $V_2 = V_1A_1/A_2$. The mass flow rate is obtained by $\dot{m} = \rho V_1A_1$.

Assume that the velocity profile is nearly uniform so that β is approximately unity. The force exerted on the fluid by the bend has x and y components; these can be found from Eq. (6-11). The x component gives

$$F_x = \dot{m}(V_{2x} - V_{1x}) + p_1A_{1x} + p_2A_{2x}$$

while the y component gives

$$F_y = \dot{m}(V_{2y} - V_{1y}) + p_1A_{1y} + p_2A_{2y}$$

The velocity components are $V_{1x} = V_1$, $V_{1y} = 0$, $V_{2x} = V_2 \cos\theta$, and $V_{2y} = V_2 \sin\theta$. The area vector components are $A_{1x} = -A_1$, $A_{1y} = 0$, $A_{2x} = A_2 \cos\theta$, and $A_{2y} = A_2 \sin\theta$. Therefore, the force components may be calculated from

$$F_x = \dot{m}(V_2\cos\theta - V_1) - p_1A_1 + p_2A_2\cos\theta$$

$$F_y = \dot{m}V_2\sin\theta + p_2A_2\sin\theta$$

The force acting on the fluid is **F;** the equal and opposite force exerted by the fluid on the bend is **−F.**

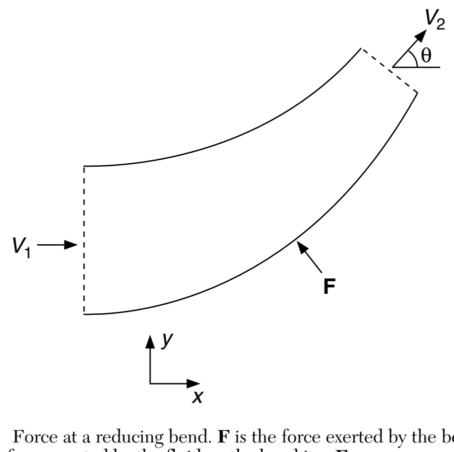

FIG. 6-5 Force at a reducing bend. **F** is the force exerted by the bend on the fluid. The force exerted by the fluid on the bend is **−F.**

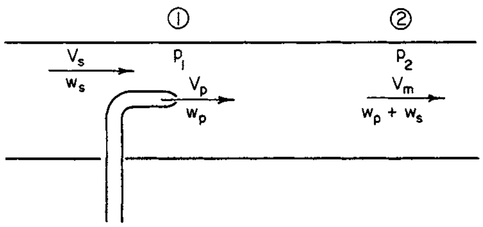

FIG. 6-6 Draft-tube ejector.

Example 2: Simplified Ejector Figure 6-6 shows a very simplified sketch of an ejector, a device that uses a high velocity primary fluid to pump another (secondary) fluid. The continuity and momentum equations may be applied on the control volume with inlet and outlet surfaces 1 and 2 as indicated in the figure. The cross-sectional area is uniform, $A_1 = A_2 = A$. Let the mass flow rates and velocities of the primary and secondary fluids be $\dot{m}_p$, $\dot{m}_s$, V_p and V_s. Assume for simplicity that the density is uniform. Conservation of mass gives $\dot{m}_2 = \dot{m}_p + \dot{m}_s$. The exit velocity is $V_2 = \dot{m}_2/(\rho A)$. The principle momentum exchange in the ejector occurs between the two fluids. Relative to this exchange, the force exerted by the walls of the device are found to be small. Therefore, the force term F is neglected from the momentum equation. Written in the flow direction, assuming uniform velocity profiles, and using the extension of Eq. (6-11) for multiple inlets, it gives the pressure rise developed by the device:

$$(p_2 - p_1)A = (\dot{m}_p + \dot{m}_s)V_2 - \dot{m}_p V_p - \dot{m}_s V_s$$

Application of the momentum equation to ejectors of other types is discussed in Lapple (*Fluid and Particle Dynamics,* University of Delaware, Newark, 1951) and in Sec. 10 of the *Handbook.*

Example 3: Venturi Flowmeter An incompressible fluid flows through the venturi flowmeter in Fig. 6-7. An equation is needed to relate the flow rate Q to the pressure drop measured by the manometer. This problem can be solved using the mechanical energy balance. In a well-made venturi, viscous losses are negligible, the pressure drop is entirely the result of acceleration into the throat, and the flow rate predicted neglecting losses is quite accurate. The inlet area is A and the throat area is a.

With control surfaces at 1 and 2 as shown in the figure, Eq. (6-17) in the absence of losses and shaft work gives

$$\frac{p_1}{\rho} + \frac{V_1^2}{2} = \frac{p_2}{\rho} + \frac{V_2^2}{2}$$

The continuity equation gives $V_2 = V_1 A/a$, and $V_1 = Q/A$. The pressure drop measured by the manometer is $p_1 - p_2 = (\rho_m - \rho)g\Delta z$. Substituting these relations into the energy balance and rearranging, the desired expression for the flow rate is found.

$$Q = \frac{1}{A}\sqrt{\frac{2(\rho_m - \rho)g\Delta z}{\rho[(A/a)^2 - 1]}}$$

Example 4: Plane Poiseuille Flow An incompressible Newtonian fluid flows at a steady rate in the x direction between two very large flat plates, as shown in Fig. 6-8. The flow is laminar. The velocity profile is to be found. This example is found in most fluid mechanics textbooks; the solution presented here closely follows Denn.

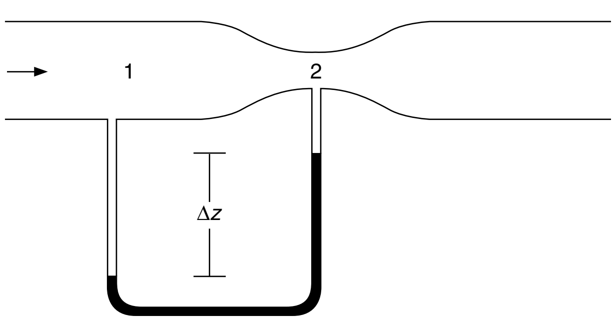

FIG. 6-7 Venturi flowmeter.

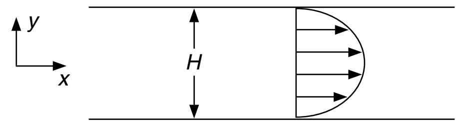

FIG. 6-8 Plane Poiseuille flow.

This problem requires use of the microscopic balance equations because the velocity is to be determined as a function of position. The boundary conditions for this flow result from the no-slip condition. All three velocity components must be zero at the plate surfaces, $y = H/2$ and $y = -H/2$.

Assume that the flow is **fully developed,** that is, all velocity derivatives vanish in the x direction. Since the flow field is infinite in the z direction, all velocity derivatives should be zero in the z direction. Therefore, velocity components are a function of y alone. It is also assumed that there is no flow in the z direction, so $v_z = 0$. The continuity equation Eq. (6-21), with $v_z = 0$ and $\partial v_x/\partial x = 0$, reduces to

$$\frac{dv_y}{dy} = 0$$

Since $v_y = 0$ at $y = \pm H/2$, the continuity equation integrates to $v_y = 0$. This is a direct result of the assumption of fully developed flow.

The Navier-Stokes equations are greatly simplified when it is noted that $v_y = v_z = 0$ and $\partial v_x/\partial x = \partial v_x/\partial z = \partial v_x/\partial t = 0$. The three components are written in terms of the equivalent pressure P:

$$0 = -\frac{\partial P}{\partial x} + \mu\frac{\partial^2 v_x}{\partial y^2}$$

$$0 = -\frac{\partial P}{\partial y}$$

$$0 = -\frac{\partial P}{\partial z}$$

The latter two equations require that P is a function only of x, and therefore $\partial P/\partial x = dP/dx$. Inspection of the first equation shows one term which is a function only of x and one which is only a function of y. This requires that both terms are constant. The pressure gradient $-dP/dx$ is constant. The x-component equation becomes

$$\frac{d^2 v_x}{dy^2} = \frac{1}{\mu}\frac{dP}{dx}$$

Two integrations of the x-component equation give

$$v_x = \frac{1}{2\mu}\frac{dP}{dx}y^2 + C_1 y + C_2$$

where the constants of integration C_1 and C_2 are evaluated from the boundary conditions $v_x = 0$ at $y = \pm H/2$. The result is

$$v_x = \frac{H^2}{8\mu}\left(-\frac{dP}{dx}\right)\left[1 - \left(\frac{2y}{H}\right)^2\right]$$

This is a **parabolic** velocity distribution. The average velocity $V = (1/H)\int_{-H/2}^{H/2} v_x\, dy$ is

$$V = \frac{H^2}{12\mu}\left(-\frac{dP}{dx}\right)$$

This flow is one-dimensional, as there is only one nonzero velocity component, v_x, which, along with the pressure, varies in only one coordinate direction.

INCOMPRESSIBLE FLOW IN PIPES AND CHANNELS

Mechanical Energy Balance The mechanical energy balance, Eq. (6-16), for **fully developed** incompressible flow in a straight circular pipe of constant diameter D reduces to

$$\frac{p_1}{\rho} + gz_1 = \frac{p_2}{\rho} + gz_2 + l_v \tag{6-30}$$

In terms of the equivalent pressure, $P \equiv p + \rho gz$,

$$P_1 - P_2 = \rho l_v \tag{6-31}$$

The pressure drop due to frictional losses l_v is proportional to pipe length L for fully developed flow and may be denoted as the (positive) quantity $\Delta P \equiv P_1 - P_2$.

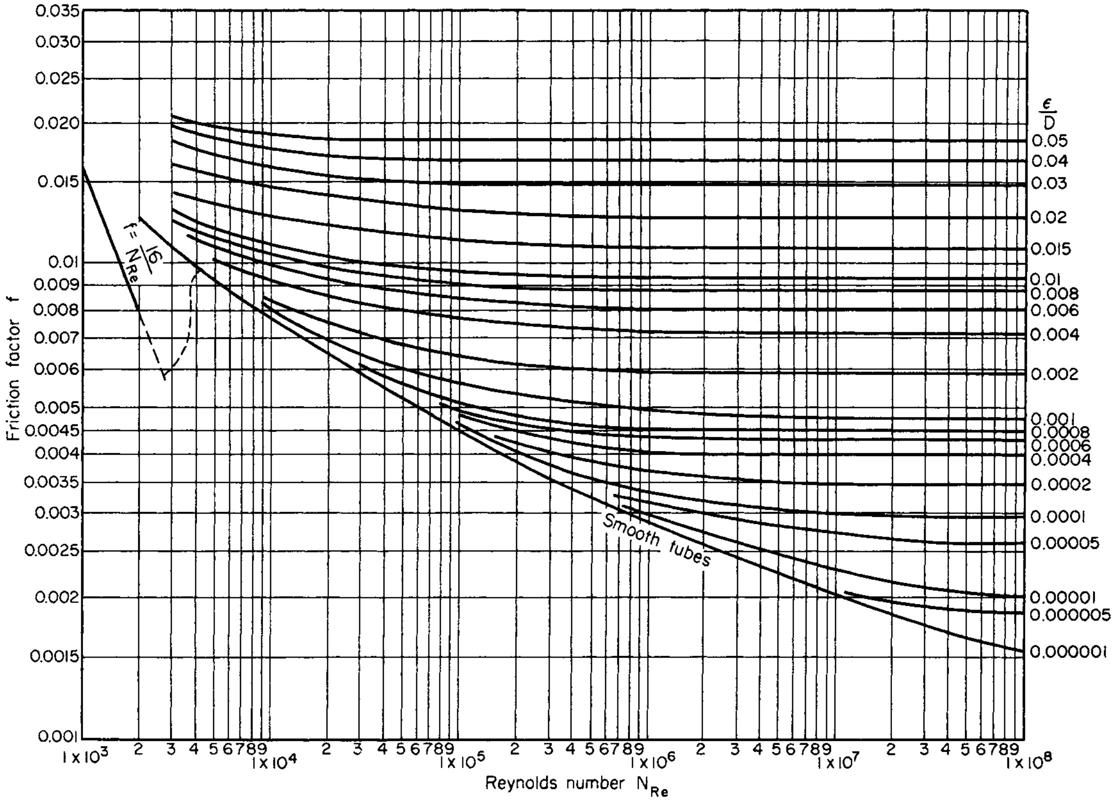

FIG. 6-9 Fanning Friction Factors. Reynolds number Re = $D V \rho/\mu$, where D = pipe diameter, V = velocity, ρ = fluid density, and μ = fluid viscosity. (*Based on Moody,* Trans. ASME, ***66,*** *671* [*1944*].)

Friction Factor and Reynolds Number For a Newtonian fluid in a smooth pipe, dimensional analysis relates the frictional pressure drop per unit length $\Delta P/L$ to the pipe diameter D, density ρ, viscosity μ, and average velocity V through two dimensionless groups, the **Fanning friction factor** f and the **Reynolds number Re.**

$$f \equiv \frac{D\Delta P}{2\rho V^2 L} \tag{6-32}$$

$$\text{Re} \equiv \frac{DV\rho}{\mu} \tag{6-33}$$

For smooth pipe, the friction factor is a function only of the Reynolds number. In rough pipe, the relative roughness ϵ/D also affects the friction factor. Figure 6-9 plots f as a function of Re and ϵ/D. Values of ϵ for various materials are given in Table 6-1. The Fanning friction factor should not be confused with the Darcy friction factor used by Moody (*Trans. ASME,* **66,** 671 [1944]), which is four times greater. Using the momentum equation, the stress at the wall of the pipe may be expressed in terms of the friction factor:

$$\tau_w = f\,\frac{\rho V^2}{2} \tag{6-34}$$

Laminar and Turbulent Flow Below a **critical Reynolds number** of about 2,100, the flow is laminar; over the range 2,100 < Re < 5,000 there is a transition to turbulent flow. Reliable correlations for the friction factor in transitional flow are not available. For laminar flow, the Hagen-Poiseuille equation

$$f = \frac{16}{\text{Re}} \qquad \text{Re} \le 2{,}100 \tag{6-35}$$

TABLE 6-1 Values of Surface Roughness for Various Materials*

Material	Surface roughness ϵ, mm
Drawn tubing (brass, lead, glass, and the like)	0.00152
Commercial steel or wrought iron	0.0457
Asphalted cast iron	0.122
Galvanized iron	0.152
Cast iron	0.259
Wood stove	0.183–0.914
Concrete	0.305–3.05
Riveted steel	0.914–9.14

* From Moody, *Trans. Am. Soc. Mech. Eng.,* **66,** 671–684 (1944); *Mech. Eng.,* **69,** 1005–1006 (1947). Additional values of ε for various types or conditions of concrete wrought-iron, welded steel, riveted steel, and corrugated-metal pipes are given in Brater and King, *Handbook of Hydraulics,* 6th ed., McGraw-Hill, New York, 1976, pp. 6-12–6-13. To convert millimeters to feet, multiply by 3.281×10^{-3}.

may be derived from the Navier-Stokes equation and is in excellent agreement with experimental data. It may be rewritten in terms of volumetric flow rate, $Q = V\pi D^2/4$, as

$$Q = \frac{\pi \Delta P D^4}{128\mu L} \qquad \text{Re} \le 2{,}100 \tag{6-36}$$

For turbulent flow in smooth tubes, the Blasius equation gives the friction factor accurately for a wide range of Reynolds numbers.

$$f = \frac{0.079}{\text{Re}^{0.25}} \qquad 4{,}000 < \text{Re} < 10^5 \tag{6-37}$$

The Colebrook formula (Colebrook, *J. Inst. Civ. Eng.* [*London*], **11,** 133–156 [1938–39]) gives a good approximation for the f-Re-(ϵ/D) data for rough pipes over the entire turbulent flow range:

$$\frac{1}{\sqrt{f}} = -4 \log \left[\frac{\epsilon}{3.7D} + \frac{1.256}{\text{Re}\sqrt{f}} \right] \qquad \text{Re} > 4{,}000 \qquad (6\text{-}38)$$

Equation (6-38) was used to construct the curves in the turbulent flow regime in Fig. 6-9.

An equation by Churchill (*Chem. Eng.,* **84**[24], 91–92 [Nov. 7, 1977]) approximating the Colebrook formula offers the advantage of being explicit in f:

$$\frac{1}{\sqrt{f}} = -4 \log \left[\frac{0.27\epsilon}{D} + \left(\frac{7}{\text{Re}} \right)^{0.9} \right] \qquad \text{Re} > 4{,}000 \qquad (6\text{-}39)$$

Churchill also provided a single equation that may be used for Reynolds numbers in laminar, transitional, and turbulent flow, closely fitting f = 16/Re in the laminar regime, and the Colebrook formula, Eq. (6-38), in the turbulent regime. It also gives unique, reasonable values in the transition regime, where the friction factor is uncertain.

$$f = 2\left[\left(\frac{8}{\text{Re}} \right)^{12} + \frac{1}{(A + B)^{3/2}} \right]^{1/12} \qquad (6\text{-}40)$$

where

$$A = \left[2.457 \ln \frac{1}{(7/\text{Re})^{0.9} + 0.27\varepsilon/D} \right]^{16}$$

and

$$B = \left(\frac{37{,}530}{\text{Re}} \right)^{16}$$

In laminar flow, f is independent of ϵ/D. In turbulent flow, the friction factor for rough pipe follows the smooth tube curve for a range of Reynolds numbers (hydraulically smooth flow). For greater Reynolds numbers, f deviates from the smooth pipe curve, eventually becoming independent of Re. This region, often called *complete turbulence,* is frequently encountered in commercial pipe flows.

Two common pipe flow problems are calculation of pressure drop given the flow rate (or velocity) and calculation of flow rate (or velocity) given the pressure drop. When flow rate is given, the Reynolds number may be calculated directly to determine the flow regime, so that the appropriate relations between f and Re (or pressure drop and flow rate or velocity) can be selected. When flow rate is specified and the flow is turbulent, Eq. (6-39) or (6-40), being explicit in f, may be preferable to Eq. (6-38), which is implicit in f and pressure drop.

When the pressure drop is given and the velocity and flow rate are to be determined, the Reynolds number cannot be computed directly, since the velocity is unknown. Instead of guessing and checking the flow regime, it may be useful to observe that the quantity $\text{Re}\sqrt{f} = (D^{3/2}/\mu)\sqrt{\rho\,\Delta P/(2L)}$, appearing in the Colebrook equation (6-38), does not include velocity and so can be computed directly. The upper limit Re = 2,100 for laminar flow and use of Eq. (6-35) corresponds to $\text{Re}\sqrt{f}$ = 183. For smooth pipe, the lower limit Re = 4,000 for the Colebrook equation corresponds to $\text{Re}\sqrt{f}$ = 400. Thus, at least for smooth pipes, the flow regime can be determined without trial and error from $\Delta P/L$, μ, ρ, and D. When pressure drop is given, Eq. (6-38), being explicit in velocity, is preferable to Eqs. (6-39) and (6-40), which are implicit in velocity.

As Fig. 6-9 suggests, the friction factor is uncertain in the transition range, and a conservative choice should be made for design purposes.

Velocity Profiles In laminar flow, the solution of the Navier-Stokes equation, corresponding to the Hagen-Poiseuille equation, gives the velocity v as a function of radial position r in a circular pipe of radius R in terms of the average velocity $V = Q/A$. The **parabolic** profile, with centerline velocity twice the average velocity, is shown in Fig. 6-10.

$$v = 2V\left(1 - \frac{r^2}{R^2}\right) \qquad (6\text{-}41)$$

In turbulent flow, the velocity profile is much more blunt, with most of the velocity gradient being in a region near the wall, described by a **universal** velocity profile. It is characterized by a **viscous sublayer,** a **turbulent core,** and a **buffer zone** in between.

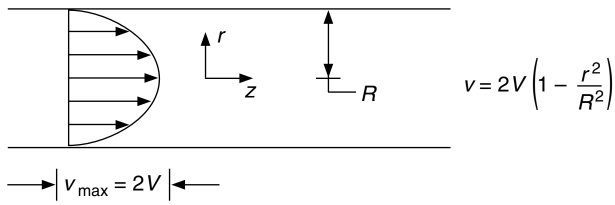

FIG. 6-10 Parabolic velocity profile for laminar flow in a pipe, with average velocity V.

Viscous sublayer

$$u_+ = y_+ \qquad \text{for} \qquad y_+ < 5 \qquad (6\text{-}42)$$

Buffer zone

$$u_+ = 5.00 \ln y_+ - 3.05 \qquad \text{for} \qquad 5 < y_+ < 30 \qquad (6\text{-}43)$$

Turbulent core

$$u_+ = 2.5 \ln y_+ + 5.5 \qquad \text{for} \qquad y_+ > 30 \qquad (6\text{-}44)$$

Here, $u_+ = v/u_*$ is the dimensionless, time-averaged axial velocity, $u_* = \sqrt{\tau_w/\rho}$ is the **friction velocity** and $\tau_w = f\rho V^2/2$ is the wall stress. The friction velocity is of the order of the root mean square velocity fluctuation perpendicular to the wall in the turbulent core. The dimensionless distance from the wall is $y_+ = yu_*\rho/\mu$. The universal velocity profile is valid in the wall region for any cross-sectional channel shape. For incompressible flow in constant diameter circular pipes, $\tau_w = D\Delta P/4L$ where ΔP is the pressure drop in length L. In circular pipes, Eq. (6-44) gives a surprisingly good fit to experimental results over the entire cross section of the pipe, even though it is based on assumptions which are valid only near the pipe wall.

For rough pipes, the velocity profile in the turbulent core is given by

$$u_+ = 2.5 \ln y/\epsilon + 8.5 \qquad \text{for} \qquad y_+ > 30 \qquad (6\text{-}45)$$

when the dimensionless roughness $\epsilon_+ = \epsilon u_*\rho/\mu$ is greater than 5 to 10; for smaller ϵ_+, the velocity profile in the turbulent core is unaffected by roughness.

For velocity profiles in the transition region, see Patel and Head (*J. Fluid Mech.,* **38,** part 1, 181–201 [1969]) where profiles over the range 1,500 < Re < 10,000 are reported.

Entrance and Exit Effects In the entrance region of a pipe, some distance is required for the flow to adjust from upstream conditions to the fully developed flow pattern. This distance depends on the Reynolds number and on the flow conditions upstream. For a uniform velocity profile at the pipe entrance, the computed length in laminar flow required for the centerline velocity to reach 99 percent of its fully developed value is (Dombrowski, Foumeny, Ookawara, and Riza, *Can. J. Chem. Engr.,* **71,** 472–476 [1993])

$$L_{ent}/D = 0.370 \exp(-0.148\text{Re}) + 0.0550\text{Re} + 0.260 \qquad (6\text{-}46)$$

In turbulent flow, the entrance length is about

$$L_{ent}/D = 40 \qquad (6\text{-}47)$$

The frictional losses in the entrance region are larger than those for the same length of fully developed flow. (See the subsection, "Frictional Losses in Pipeline Elements," following.) At the pipe exit, the velocity profile also undergoes rearrangement, but the exit length is much shorter than the entrance length. At low Re, it is about one pipe radius. At Re > 100, the exit length is essentially 0.

Residence Time Distribution For laminar Newtonian pipe flow, the cumulative residence time distribution $F(\theta)$ is given by

$$F(\theta) = 0 \qquad \text{for} \qquad \theta < \frac{\theta_{avg}}{2}$$

$$F(\theta) = 1 - \frac{1}{4}\left(\frac{\theta_{avg}}{\theta}\right)^2 \qquad \text{for} \qquad \theta \geq \frac{\theta_{avg}}{2} \qquad (6\text{-}48)$$

where $F(\theta)$ is the fraction of material which resides in the pipe for less than time θ and θ_{avg} is the average residence time, $\theta = V/L$.

The residence time distribution in long transfer lines may be made narrower (more uniform) with the use of **flow inverters** or **static mixing elements.** These devices exchange fluid between the wall and central regions. Variations on the concept may be used to provide effective mixing of the fluid. See Godfrey ("Static Mixers," in Harnby, Edwards, and Nienow, *Mixing in the Process Industries,* 2d ed., Butterworth Heinemann, Oxford, 1992); Etchells and Meyer ("Mixing in Pipelines, in Paul, Atiemo-Obeng, and Kresta, *Handbook of Industrial Mixing*, Wiley Interscience, Hoboken, N.J., 2004).

A theoretically derived equation for laminar flow in helical pipe coils by Ruthven (*Chem. Eng. Sci.,* **26,** 1113–1121 [1971]; **33,** 628–629 [1978]) is given by

$$F(\theta) = 1 - \left(\frac{1}{4}\right)\left[\frac{\theta_{avg}}{\theta}\right]^{2.81} \qquad \text{for} \qquad 0.5 < \frac{\theta_{avg}}{\theta} < 1.63 \tag{6-49}$$

and was substantially confirmed by Trivedi and Vasudeva (*Chem. Eng. Sci.,* **29,** 2291–2295 [1974]) for $0.6 < \text{De} < 6$ and $0.0036 < D/D_c < 0.097$ where $\text{De} = \text{Re}\sqrt{D/D_c}$ is the Dean number and D_c is the diameter of curvature of the coil. Measurements by Saxena and Nigam (*Chem. Eng. Sci.,* **34,** 425–426 [1979]) indicate that such a distribution will hold for De > 1. The residence time distribution for helical coils is narrower than for straight circular pipes, due to the secondary flow which exchanges fluid between the wall and center regions.

In turbulent flow, axial mixing is usually described in terms of turbulent diffusion or dispersion coefficients, from which cumulative residence time distribution functions can be computed. Davies (*Turbulence Phenomena,* Academic, New York, 1972, p. 93) gives $D_L = 1.01\nu\text{Re}^{0.875}$ for the longitudinal dispersion coefficient. Levenspiel (*Chemical Reaction Engineering*, 2d ed., Wiley, New York, 1972, pp. 253–278) discusses the relations among various residence time distribution functions, and the relation between dispersion coefficient and residence time distribution.

Noncircular Channels Calculation of frictional pressure drop in noncircular channels depends on whether the flow is laminar or turbulent, and on whether the channel is full or open. For **turbulent flow** in **ducts running full,** the **hydraulic diameter** D_H should be substituted for D in the friction factor and Reynolds number definitions, Eqs. (6-32) and (6-33). The hydraulic diameter is defined as **four times the channel cross-sectional area divided by the wetted perimeter.** For example, the hydraulic diameter for a circular pipe is $D_H = D$, for an annulus of inner diameter d and outer diameter D, $D_H = D - d$, for a rectangular duct of sides a, b, $D_H = ab/[2(a + b)]$. The **hydraulic radius** R_H is defined as **one-fourth** of the hydraulic diameter.

With the hydraulic diameter subsitituted for D in f and Re, Eqs. (6-37) through (6-40) are good approximations. Note that V appearing in f and Re is the actual average velocity $V = Q/A$; for noncircular pipes; it is **not** $Q/(\pi D_H^2/4)$. The pressure drop should be calculated from the friction factor for noncircular pipes. Equations relating Q to ΔP and D for circular pipes **may not be used** for noncircular pipes with D replaced by D_H because $V \neq Q/(\pi D_H^2/4)$.

Turbulent flow in noncircular channels is generally accompanied by secondary flows perpendicular to the axial flow direction (Schlichting). These flows may cause the pressure drop to be slightly greater than that computed using the hydraulic diameter method. For data on pressure drop in annuli, see Brighton and Jones (*J. Basic Eng.,* **86,** 835–842 [1964]); Okiishi and Serovy (*J. Basic Eng.,* **89,** 823–836 [1967]); and Lawn and Elliot (*J. Mech. Eng. Sci.,* **14,** 195–204 [1972]). For rectangular ducts of large aspect ratio, Dean (*J. Fluids Eng.,* **100,** 215–233 [1978]) found that the numerator of the exponent in the Blasius equation (6-37) should be increased to 0.0868. Jones (*J. Fluids Eng.,* **98,** 173–181 [1976]) presents a method to improve the estimation of friction factors for rectangular ducts using a modification of the hydraulic diameter–based Reynolds number.

The hydraulic diameter method does not work well for **laminar flow** because the shape affects the flow resistance in a way that cannot be expressed as a function only of the ratio of cross-sectional area to wetted perimeter. For some shapes, the Navier-Stokes equations have been integrated to yield relations between flow rate and pressure drop. These relations may be expressed in terms of **equivalent diameters** D_E defined to make the relations reduce to the second form of the Hagen-Poiseulle equation, Eq. (6-36); that is, $D_E \equiv (128Q\mu L/\pi\Delta P)^{1/4}$. **Equivalent diameters are not the same as hydraulic diameters.** Equivalent diameters yield the correct relation between flow rate and pressure drop when substituted into Eq. (6-36), but not Eq. (6-35) because $V \neq Q/(\pi D_E/4)$. Equivalent diameter D_E is not to be used in the friction factor and Reynolds number; $f \neq 16/\text{Re}$ using the equivalent diameters defined in the following. This situation is, by arbitrary definition, opposite to that for the hydraulic diameter D_H used for turbulent flow.

Ellipse, semiaxes a and b (Lamb, *Hydrodynamics,* 6th ed., Dover, New York, 1945, p. 587):

$$D_E = \left(\frac{32a^3b^3}{a^2 + b^2}\right)^{1/4} \tag{6-50}$$

Rectangle, width a, height b (Owen, *Trans. Am. Soc. Civ. Eng.,* **119,** 1157–1175 [1954]):

$$D_E = \left(\frac{128ab^3}{\pi K}\right)^{1/4} \tag{6-51}$$

a/b =	1	1.5	2	3	4	5	10	∞
K =	28.45	20.43	17.49	15.19	14.24	13.73	12.81	12

Annulus, inner diameter D_1, outer diameter D_2 (Lamb, op. cit., p. 587):

$$D_E = \left\{(D_2^2 - D_1^2)\left[D_2^2 + D_1^2 - \frac{D_2^2 - D_1^2}{\ln (D_2/D_1)}\right]\right\}^{1/4} \tag{6-52}$$

For isosceles triangles and regular polygons, see Sparrow (*AIChE J.,* **8,** 599–605 [1962]), Carlson and Irvine (*J. Heat Transfer,* **83,** 441–444 [1961]), Cheng (*Proc. Third Int. Heat Transfer Conf.,* New York, **1,** 64–76 [1966]), and Shih (*Can. J. Chem. Eng.,* **45,** 285–294 [1967]).

The critical Reynolds number for **transition from laminar to turbulent flow** in noncircular channels varies with channel shape. In rectangular ducts, $1{,}900 < \text{Re}_c < 2{,}800$ (Hanks and Ruo, *Ind. Eng. Chem. Fundam.,* **5,** 558–561 [1966]). In triangular ducts, $1{,}600 < \text{Re}_c < 1{,}800$ (Cope and Hanks, *Ind. Eng. Chem. Fundam.,* **11,** 106–117 [1972]; Bandopadhayay and Hinwood, *J. Fluid Mech.,* **59,** 775–783 [1973]).

Nonisothermal Flow For nonisothermal flow of **liquids,** the friction factor may be increased if the liquid is being cooled or decreased if the liquid is being heated, because of the effect of temperature on viscosity near the wall. In shell and tube heat-exchanger design, the recommended practice is to first estimate f using the bulk mean liquid temperature over the tube length. Then, in laminar flow, the result is divided by $(\mu_a/\mu_w)^{0.23}$ in the case of cooling or $(\mu_a/\mu_w)^{0.38}$ in the case of heating. For turbulent flow, f is divided by $(\mu_a/\mu_w)^{0.11}$ in the case of cooling or $(\mu_a/\mu_w)^{0.17}$ in case of heating. Here, μ_a is the viscosity at the average bulk temperature and μ_w is the viscosity at the average wall temperature (Seider and Tate, *Ind. Eng. Chem.,* **28,** 1429–1435 [1936]). In the case of rough commercial pipes, rather than heat-exchanger tubing, it is common for flow to be in the "complete" turbulence regime where f is independent of Re. In such cases, the friction factor should not be corrected for wall temperature. If the liquid density varies with temperature, the average bulk density should be used to calculate the pressure drop from the friction factor. In addition, a (usually small) correction may be applied for acceleration effects by adding the term $G^2[(1/\rho_2) - (1/\rho_1)]$ from the mechanical energy balance to the pressure drop $\Delta P = P_1 - P_2$, where G is the mass velocity. This acceleration results from small compressibility effects associated with temperature-dependent density. Christiansen and Gordon (*AIChE J.,* **15,** 504–507 [1969]) present equations and charts for frictional loss in laminar nonisothermal flow of Newtonian and non-Newtonian liquids heated or cooled with constant wall temperature.

Frictional dissipation of mechanical energy can result in significant heating of fluids, particularly for very viscous liquids in small channels. Under adiabatic conditions, the bulk liquid temperature rise is given by $\Delta T = \Delta P/C_v\rho$ for incompressible flow through a channel of constant cross-sectional area. For flow of polymers, this amounts to about 4°C per 10 MPa pressure drop, while for hydrocarbon liquids it is about

6°C per 10 MPa. The temperature rise in laminar flow is highly nonuniform, being concentrated near the pipe wall where most of the dissipation occurs. This may result in significant viscosity reduction near the wall, and greatly increased flow or reduced pressure drop, and a flattened velocity profile. Compensation should generally be made for the heat effect when ΔP exceeds 1.4 MPa (203 psi) for adiabatic walls or 3.5 MPa (508 psi) for isothermal walls (Gerard, Steidler, and Appeldoorn, *Ind. Eng. Chem. Fundam.,* **4,** 332–339 [1969]).

Open Channel Flow For flow in **open channels,** the data are largely based on experiments with water in turbulent flow, in channels of sufficient roughness that there is no Reynolds number effect. The hydraulic radius approach may be used to estimate a friction factor with which to compute friction losses. Under conditions of **uniform flow** where liquid depth and cross-sectional area do not vary significantly with position in the flow direction, there is a balance between gravitational forces and wall stress, or equivalently between frictional losses and potential energy change. The mechanical energy balance reduces to $l_v = g(z_1 - z_2)$. In terms of the friction factor and hydraulic diameter or hydraulic radius,

$$l_v = \frac{2fV^2L}{D_H} = \frac{fV^2L}{2R_H} = g(z_1 - z_2) \tag{6-53}$$

The hydraulic radius is the cross-sectional area divided by the wetted perimeter, where the wetted perimeter *does not include the free surface.* Letting $S = \sin\theta$ = channel slope (elevation loss per unit length of channel, θ = angle between channel and horizontal), Eq. (6-53) reduces to

$$V = \sqrt{\frac{2gSR_H}{f}} \tag{6-54}$$

The most often used friction correlation for open channel flows is due to Manning (*Trans. Inst. Civ. Engrs. Ireland,* **20,** 161 [1891]) and is equivalent to

$$f = \frac{29n^2}{R_H^{1/3}} \tag{6-55}$$

where n is the channel roughness, with dimensions of (length)$^{1/6}$. Table 6-2 gives roughness values for several channel types.

For gradual changes in channel cross section and liquid depth, and for slopes less than 10°, the momentum equation for a rectangular channel of width b and liquid depth h may be written as a differential equation in the flow direction x.

$$\frac{dh}{dx}(1 - \mathrm{Fr}) - \mathrm{Fr}\left(\frac{h}{b}\right)\frac{db}{dx} = S - \frac{fV^2(b + 2h)}{2gbh} \tag{6-56}$$

For a given fixed flow rate $Q = Vbh$, and channel width profile $b(x)$, Eq. (6-56) may be integrated to determine the liquid depth profile $h(x)$. The dimensionless Froude number is $\mathrm{Fr} = V^2/gh$. When Fr = 1, the flow is **critical,** when Fr < 1, the flow is **subcritical,** and when Fr > 1, the flow is **supercritical.** Surface disturbances move at a wave velocity $c = \sqrt{gh}$; they cannot propagate upstream in supercritical flows. The **specific energy** E_{sp} is nearly constant.

$$E_{sp} = h + \frac{V^2}{2g} \tag{6-57}$$

This equation is cubic in liquid depth. Below a minimum value of E_{sp} there are no real positive roots; above the minimum value there are two positive real roots. At this minimum value of E_{sp} the flow is critical; that is, Fr = 1, $V = \sqrt{gh}$, and $E_{sp} = (3/2)h$. Near critical flow conditions, wave motion and sudden depth changes called **hydraulic jumps** are likely. Chow (*Open Channel Hydraulics,* McGraw-Hill, New York, 1959) discusses the numerous surface profile shapes which may exist in nonuniform open channel flows.

For flow over a sharp-crested weir of width b and height L, from a liquid depth H, the flow rate is given approximately by

$$Q = \frac{2}{3} C_d b\sqrt{2g}(H - L)^{3/2} \tag{6-58}$$

where $C_d \approx 0.6$ is a discharge coefficient. Flow through notched weirs is described under flow meters in Sec. 10 of the *Handbook.*

Non-Newtonian Flow For **isothermal laminar flow** of time-independent non-Newtonian liquids, integration of the Cauchy momentum equations yields the fully developed velocity profile and flow rate–pressure drop relations. For the **Bingham plastic** fluid described by Eq. (6-3), in a pipe of diameter D and a pressure drop per unit length $\Delta P/L$, the flow rate is given by

$$Q = \frac{\pi D^3 \tau_w}{32\mu_\infty}\left[1 - \frac{4\tau_y}{3\tau_w} + \frac{\tau_y^4}{3\tau_w^4}\right] \tag{6-59}$$

where the wall stress is $\tau_w = D\Delta P/(4L)$. The velocity profile consists of a central nondeforming plug of radius $r_P = 2\tau_y/(\Delta P/L)$ and an annular deforming region. The velocity profile in the annular region is given by

$$v_z = \frac{1}{\mu_\infty}\left[\frac{\Delta P}{4L}(R^2 - r^2) - \tau_y(R - r)\right] \qquad r_P \le r \le R \tag{6-60}$$

where r is the radial coordinate and R is the pipe radius. The velocity of the central, nondeforming plug is obtained by setting $r = r_P$ in Eq. (6-60). When Q is given and Eq. (6-59) is to be solved for τ_w and the pressure drop, multiple positive roots for the pressure drop may be found. The root corresponding to $\tau_w < \tau_y$ is physically unrealizable, as it corresponds to $r_p > R$ and the pressure drop is insufficient to overcome the yield stress.

For a **power law fluid,** Eq. (6-4), with constant properties K and n, the flow rate is given by

$$Q = \pi\left(\frac{\Delta P}{2KL}\right)^{1/n}\left(\frac{n}{1 + 3n}\right)R^{(1+3n)/n} \tag{6-61}$$

and the velocity profile by

$$v_z = \left(\frac{\Delta P}{2KL}\right)^{1/n}\left(\frac{n}{1 + n}\right)[R^{(1+n)/n} - r^{(1+n)/n}] \tag{6-62}$$

Similar relations for other non-Newtonian fluids may be found in Govier and Aziz and in Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977).

For steady-state laminar flow of any time-independent viscous fluid, at average velocity V in a pipe of diameter D, the Rabinowitsch-Mooney relations give a general relationship for the shear rate at the pipe wall.

$$\dot{\gamma}_w = \frac{8V}{D}\left(\frac{1 + 3n'}{4n'}\right) \tag{6-63}$$

where n' is the slope of a plot of $D\Delta P/(4L)$ versus $8V/D$ on logarithmic coordinates,

$$n' = \frac{d \ln [D\Delta P/(4L)]}{d \ln (8V/D)} \tag{6-64}$$

TABLE 6-2 Average Values of *n* for Manning Formula, Eq. (6-55)

Surface	n, m$^{1/6}$	n, ft$^{1/6}$
Cast-iron pipe, fair condition	0.014	0.011
Riveted steel pipe	0.017	0.014
Vitrified sewer pipe	0.013	0.011
Concrete pipe	0.015	0.012
Wood-stave pipe	0.012	0.010
Planed-plank flume	0.012	0.010
Semicircular metal flumes, smooth	0.013	0.011
Semicircular metal flumes, corrugated	0.028	0.023
Canals and ditches		
Earth, straight and uniform	0.023	0.019
Winding sluggish canals	0.025	0.021
Dredged earth channels	0.028	0.023
Natural-stream channels		
Clean, straight bank, full stage	0.030	0.025
Winding, some pools and shoals	0.040	0.033
Same, but with stony sections	0.055	0.045
Sluggish reaches, very deep pools, rather weedy	0.070	0.057

SOURCE: Brater and King, *Handbook of Hydraulics,* 6th ed., McGraw-Hill, New York, 1976, p. 7-22. For detailed information, see Chow, *Open-Channel Hydraulics,* McGraw-Hill, New York, 1959, pp. 110–123.

By plotting capillary viscometry data this way, they can be used directly for pressure drop design calculations, or to construct the rheogram for the fluid. For pressure drop calculation, the flow rate and diameter determine the velocity, from which $8V/D$ is calculated and $D\Delta P/(4L)$ read from the plot. For a Newtonian fluid, $n' = 1$ and the shear rate at the wall is $\dot{\gamma} = 8V/D$. For a power law fluid, $n' = n$. To construct a rheogram, n' is obtained from the slope of the experimental plot at a given value of $8V/D$. The shear rate at the wall is given by Eq. (6-63) and the corresponding shear stress at the wall is $\tau_w = D\Delta P/(4L)$ read from the plot. By varying the value of $8V/D$, the shear rate versus shear stress plot can be constructed.

The generalized approach of Metzner and Reed (*AIChE J.,* **1,** 434 [1955]) for time-independent non-Newtonian fluids defines a modified Reynolds number as

$$\text{Re}_{MR} \equiv \frac{D^{n'}V^{2-n'}\rho}{K'8^{n'-1}} \tag{6-65}$$

where K' satisfies

$$\frac{D\Delta P}{4L} = K'\left(\frac{8V}{D}\right)^{n'} \tag{6-66}$$

With this definition, $f = 16/\text{Re}_{MR}$ is automatically satisfied at the value of $8V/D$ where K' and n' are evaluated. Equation (6-66) may be obtained by integration of Eq. (6-64) only when n' is a constant, as, for example, the cases of Newtonian and power law fluids. For Newtonian fluids, $K' = \mu$ and $n' = 1$; for power law fluids, $K' = K[(1 + 3n)/(4n)]^n$ and $n' = n$. For Bingham plastics, K' and n' are variable, given as a function of τ_w (Metzner, *Ind. Eng. Chem.,* **49,** 1429–1432 [1957]).

$$K = \tau_w^{1-n'}\left[\frac{\mu_\infty}{1 - 4\tau_y/3\tau_w + (\tau_y/\tau_w)^4/3}\right]^{n'} \tag{6-67}$$

$$n' = \frac{1 - 4\tau_y/(3\tau_w) + (\tau_y/\tau_w)^4/3}{1 - (\tau_y/\tau_w)^4} \tag{6-68}$$

For laminar flow of power law fluids in channels of noncircular cross section, see Schecter (*AIChE J.,* **7,** 445–448 [1961]), Wheeler and Wissler (*AIChE J.,* **11,** 207–212 [1965]), Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977), and Skelland (*Non-Newtonian Flow and Heat Transfer,* Wiley, New York, 1967).

Steady-state, fully developed laminar flows of viscoelastic fluids in straight, constant-diameter pipes show no effects of viscoelasticity. The viscous component of the constitutive equation may be used to develop the flow rate–pressure drop relations, which apply downstream of the entrance region after viscoelastic effects have disappeared. A similar situation exists for time-dependent fluids.

The **transition to turbulent flow** begins at Re_{MR} in the range of 2,000 to 2,500 (Metzner and Reed, *AIChE J.,* **1,** 434 [1955]). For Bingham plastic materials, K' and n' must be evaluated for the τ_w condition in question in order to determine Re_{MR} and establish whether the flow is laminar. An alternative method for Bingham plastics is by Hanks (Hanks, *AIChE J.,* **9,** 306 [1963]; **14,** 691 [1968]; Hanks and Pratt, *Soc. Petrol. Engrs. J.,* **7,** 342 [1967]; and Govier and Aziz, pp. 213–215). The transition from laminar to turbulent flow is influenced by **viscoelastic** properties (Metzner and Park, *J. Fluid Mech.,* **20,** 291 [1964]) with the critical value of Re_{MR} increased to beyond 10,000 for some materials.

For **turbulent flow of non-Newtonian fluids,** the design chart of Dodge and Metzner (*AIChE J.,* **5,** 189 [1959]), Fig. 6-11, is most widely used. For Bingham plastic materials in turbulent flow, it is generally assumed that stresses greatly exceed the yield stress, so that the friction factor–Reynolds number relationship for Newtonian fluids applies, with μ_∞ substituted for μ. This is equivalent to setting $n' = 1$ and $\tau_y/\tau_w = 0$ in the Dodge-Metzner method, so that $\text{Re}_{MR} = DV\rho/\mu_\infty$. Wilson and Thomas (*Can. J. Chem. Eng.,* **63,** 539–546 [1985]) give friction factor equations for turbulent flow of power law fluids and Bingham plastic fluids.

Power law fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 8.2\,\frac{1-n}{1+n} + 1.77\ln\left(\frac{1+n}{2}\right) \tag{6-69}$$

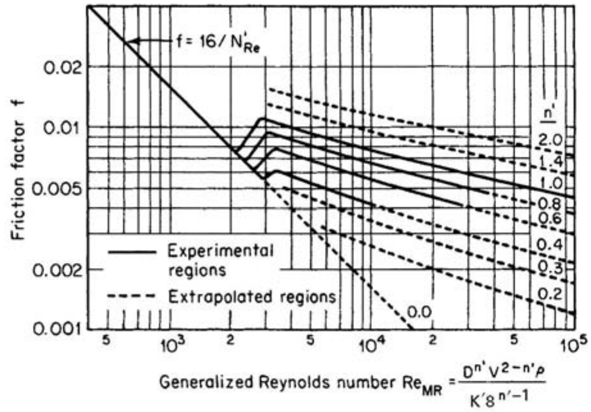

FIG. 6-11 Fanning friction factor for non-Newtonian flow. The abscissa is defined in Eq. (6-65). (*From Dodge and Metzner,* Am. Inst. Chem. Eng. J., **5,** *189* [*1959*].)

where f_N is the friction factor for Newtonian fluid evaluated at Re = $DV\rho/\mu_{eff}$ where the effective viscosity is

$$\mu_{eff} = K\left(\frac{3n+1}{4n}\right)^{n-1}\left(\frac{8V}{D}\right)^{n-1} \tag{6-70}$$

Bingham fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 1.77\ln\left(\frac{(1-\xi)^2}{1+\xi}\right) + \xi(10 + 0.884\xi) \tag{6-71}$$

where f_N is evaluated at Re = $DV\rho/\mu_\infty$ and $\xi = \tau_y/\tau_w$. Iteration is required to use this equation since $\tau_w = f\rho V^2/2$.

Drag reduction in turbulent flow can be achieved by adding soluble high molecular weight polymers in extremely low concentration to Newtonian liquids. The reduction in friction is generally believed to be associated with the viscoelastic nature of the solutions effective in the wall region. For a given polymer, there is a minimum molecular weight necessary to initiate drag reduction at a given flow rate, and a critical concentration above which drag reduction will not occur (Kim, Little, and Ting, *J. Colloid Interface Sci.,* **47,** 530–535 [1974]). Drag reduction is reviewed by Hoyt (*J. Basic Eng.,* **94,** 258–285 [1972]); Little, et al. (*Ind. Eng. Chem. Fundam.,* **14,** 283–296 [1975]) and Virk (*AIChE J.,* **21,** 625–656 [1975]). At maximum possible drag reduction in smooth pipes,

$$\frac{1}{\sqrt{f}} = -19\log\left(\frac{50.73}{\text{Re}\sqrt{f}}\right) \tag{6-72}$$

or, approximately,

$$f = \frac{0.58}{\text{Re}^{0.58}} \tag{6-73}$$

for 4,000 < Re < 40,000. The actual drag reduction depends on the polymer system. For further details, see Virk (ibid.).

Economic Pipe Diameter, Turbulent Flow The economic optimum pipe diameter may be computed so that the last increment of investment reduces the operating cost enough to produce the required minimum return on investment. For long cross-country pipelines, alloy pipes of appreciable length and complexity, or pipelines with control valves, detailed analyses of investment and operating costs should be made. Peters and Timmerhaus (*Plant Design and Economics for Chemical Engineers,* 4th ed., McGraw-Hill, New York, 1991) provide a detailed method for determining the economic optimum size. For pipelines of the lengths usually encountered in chemical plants and petroleum refineries, simplified selection charts are often adequate. In many cases there is an economic optimum velocity that is nearly independent of diameter, which may be used to estimate the economic diameter from the flow rate. For low-viscosity liquids in schedule 40 steel pipe, economic optimum velocity is typically in the range of 1.8 to 2.4 m/s (5.9 to 7.9 ft/s). For gases with density ranging

from 0.2 to 20 kg/m³ (0.013 to 1.25 lbm/ft³), the economic optimum velocity is about 40 m/s to 9 m/s (131 to 30 ft/s). Charts and rough guidelines for economic optimum size do not apply to multiphase flows.

Economic Pipe Diameter, Laminar Flow Pipelines for the transport of high-viscosity liquids are seldom designed purely on the basis of economics. More often, the size is dictated by operability considerations such as available pressure drop, shear rate, or residence time distribution. Peters and Timmerhaus (ibid., Chap. 10) provide an economic pipe diameter chart for laminar flow. For non-Newtonian fluids, see Skelland (*Non-Newtonian Flow and Heat Transfer,* Chap. 7, Wiley, New York, 1967).

Vacuum Flow When gas flows under high vacuum conditions or through very small openings, the continuum hypothesis is no longer appropriate if the channel dimension is not very large compared to the mean free path of the gas. When the mean free path is comparable to the channel dimension, flow is dominated by collisions of molecules with the wall, rather than by collisions between molecules. An approximate expression based on Brown, et al. (*J. Appl. Phys.,* **17,** 802–813 [1946]) for the mean free path is

$$\lambda = \left(\frac{2\mu}{p}\right)\sqrt{\frac{8RT}{\pi M_w}} \tag{6-74}$$

The Knudsen number Kn is the ratio of the mean free path to the channel dimension. For pipe flow, Kn = λ/D. **Molecular flow** is characterized by Kn > 1.0; continuum viscous (laminar or turbulent) flow is characterized by Kn < 0.01. **Transition** or **slip** flow applies over the range 0.01 < Kn < 1.0.

Vacuum flow is usually described with flow variables different from those used for normal pressures, which often leads to confusion. **Pumping speed** S is the actual volumetric flow rate of gas through a flow cross section. **Throughput** Q is the product of pumping speed and absolute pressure. In the SI system, Q has units of Pa·m³/s.

$$Q = Sp \tag{6-75}$$

The mass flow rate w is related to the throughput using the ideal gas law.

$$w = \frac{M_w}{RT}Q \tag{6-76}$$

Throughput is therefore proportional to mass flow rate. For a given mass flow rate, throughput is independent of pressure. The relation between throughput and pressure drop $\Delta p = p_1 - p_2$ across a flow element is written in terms of the **conductance** C. **Resistance** is the reciprocal of conductance. Conductance has dimensions of volume per time.

$$Q = C\Delta p \tag{6-77}$$

The conductance of a series of flow elements is given by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots \tag{6-78}$$

while for elements in parallel,

$$C = C_1 + C_2 + C_3 + \cdots \tag{6-79}$$

For a vacuum pump of speed S_p withdrawing from a vacuum vessel through a connecting line of conductance C, the pumping speed at the vessel is

$$S = \frac{S_pC}{S_p + C} \tag{6-80}$$

Molecular Flow Under molecular flow conditions, conductance is independent of pressure. It is proportional to $\sqrt{T/M_w}$, with the proportionality constant a function of geometry. For fully developed pipe flow,

$$C = \frac{\pi D^3}{8L}\sqrt{\frac{RT}{M_w}} \tag{6-81}$$

For an orifice of area A,

$$C = 0.40A\sqrt{\frac{RT}{M_w}} \tag{6-82}$$

TABLE 6-3 Constants for Circular Annuli

D_2/D_1	K	D_2/D_1	K
0	1.00	0.707	1.254
0.259	1.072	0.866	1.430
0.500	1.154	0.966	1.675

Conductance equations for several other geometries are given by Ryans and Roper (*Process Vacuum System Design and Operation,* Chap. 2, McGraw-Hill, New York, 1986). For a circular annulus of outer and inner diameters D_1 and D_2 and length L, the method of Guthrie and Wakerling (*Vacuum Equipment and Techniques,* McGraw-Hill, New York, 1949) may be written

$$C = 0.42K\frac{(D_1 - D_2)^2(D_1 + D_2)}{L}\sqrt{\frac{RT}{M_w}} \tag{6-83}$$

where K is a dimensionless constant with values given in Table 6-3.

For a short pipe of circular cross section, the conductance as calculated for an orifice from Eq. (6-82) is multiplied by a correction factor K which may be approximated as (Kennard, *Kinetic Theory of Gases,* McGraw-Hill, New York, 1938, pp. 306–308)

$$K = \frac{1}{1 + (L/D)} \quad \text{for} \quad 0 \le L/D \le 0.75 \tag{6-84}$$

$$K = \frac{1 + 0.8(L/D)}{1 + 1.90(L/D) + 0.6(L/D)^2} \quad \text{for} \quad L/D > 0.75 \tag{6-85}$$

For $L/D > 100$, the error in neglecting the end correction by using the fully developed pipe flow equation (6-81) is less than 2 percent. For rectangular channels, see Normand (*Ind. Eng. Chem.,* **40,** 783–787 [1948]).

Yu and Sparrow (*J. Basic Eng.,* **70,** 405–410 [1970]) give a theoretically derived chart for slot seals with or without a sheet located in or passing through the seal, giving mass flow rate as a function of the ratio of seal plate thickness to gap opening.

Slip Flow In the transition region between molecular flow and continuum viscous flow, the conductance for fully developed pipe flow is most easily obtained by the method of Brown, et al. (*J. Appl. Phys.,* **17,** 802–813 [1946]), which uses the parameter

$$X = \sqrt{\frac{8}{\pi}}\left(\frac{\lambda}{D}\right) = \left(\frac{2\mu}{p_mD}\right)\sqrt{\frac{RT}{M}} \tag{6-86}$$

where p_m is the arithmetic mean absolute pressure. A correction factor F, read from Fig. 6-12 as a function of X, is applied to the conductance

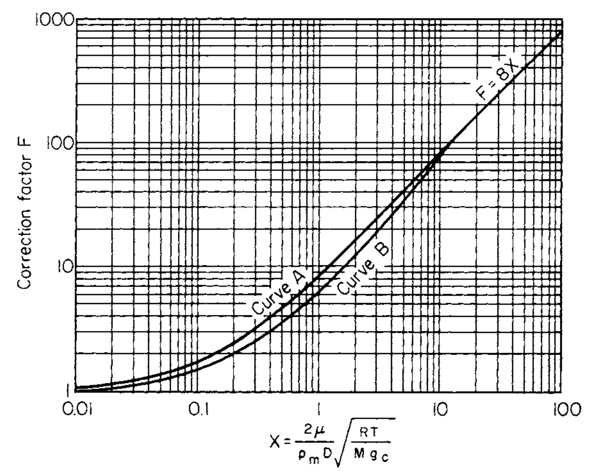

FIG. 6-12 Correction factor for Poiseuille's equation at low pressures. Curve *A:* experimental curve for glass capillaries and smooth metal tubes. (*From Brown, et al.,* J. Appl. Phys., *17, 802 [1946].*) Curve *B:* experimental curve for iron pipe (*From Riggle, courtesy of E. I. du Pont de Nemours & Co.*)

for viscous flow.

$$C = F\,\frac{\pi D^4 p_m}{128\mu L} \qquad (6\text{-}87)$$

For slip flow through **square channels,** see Milligan and Wilkerson (*J. Eng. Ind.,* **95,** 370–372 [1973]). For slip flow through **annuli,** see Maegley and Berman (*Phys. Fluids,* **15,** 780–785 [1972]).

The **pump-down time** θ for evacuating a vessel in the absence of air in-leakage is given approximately by

$$\theta = \left(\frac{V_t}{S_0}\right)\ln\left(\frac{p_1 - p_0}{p_2 - p_0}\right) \qquad (6\text{-}88)$$

where V_t = volume of vessel plus volume of piping between vessel and pump; S_0 = system speed as given by Eq. (6-80), assumed independent of pressure; p_1 = initial vessel pressure; p_2 = final vessel pressure; and p_0 = lowest pump intake pressure attainable with the pump in question. See Dushman and Lafferty (*Scientific Foundations of Vacuum Technique,* 2d ed., Wiley, New York, 1962).

The amount of inerts which has to be removed by a pumping system after the pump-down stage depends on the in-leakage of air at the various fittings, connections, and so on. Air leakage is often correlated with system volume and pressure, but this approach introduces uncertainty because the number and size of leaks does not necessily correlate with system volume, and leakage is sensitive to maintenance quality. Ryans and Roper (*Process Vacuum System Design and Operation,* McGraw-Hill, New York, 1986) present a thorough discussion of air leakage.

FRICTIONAL LOSSES IN PIPELINE ELEMENTS

The viscous or frictional loss term in the mechanical energy balance for most cases is obtained experimentally. For many common fittings found in piping systems, such as expansions, contractions, elbows, and valves, data are available to estimate the losses. Substitution into the energy balance then allows calculation of pressure drop. A common error is to assume that pressure drop and frictional losses are equivalent. Equation (6-16) shows that in addition to frictional losses, other factors such as shaft work and velocity or elevation change influence pressure drop.

Losses l_v for incompressible flow in sections of straight pipe of constant diameter may be calculated as previously described using the Fanning friction factor:

$$l_v = \frac{\Delta P}{\rho} = \frac{2fV^2L}{D} \qquad (6\text{-}89)$$

where ΔP = drop in equivalent pressure, $P = p + \rho gz$, with p = pressure, ρ = fluid density, g = acceleration of gravity, and z = elevation. Losses in the fittings of a piping network are frequently termed *minor losses* or *miscellaneous losses.* These descriptions are misleading because in process piping fitting losses are often much greater than the losses in straight piping sections.

Equivalent Length and Velocity Head Methods Two methods are in common use for estimating fitting loss. One, the **equivalent length** method, reports the losses in a piping element as the length of straight pipe which would have the same loss. For turbulent flows, the equivalent length is usually reported as a number of diameters of pipe of the same size as the fitting connection; L_e/D is given as a fixed quantity, independent of D. This approach tends to be most accurate for a single fitting size and loses accuracy with deviation from this size. For laminar flows, L_e/D correlations normally have a size dependence through a Reynolds number term.

The other method is the **velocity head** method. The term $V^2/2g$ has dimensions of length and is commonly called a *velocity head.* Application of the Bernoulli equation to the problem of frictionless discharge at velocity V through a nozzle at the bottom of a column of liquid of height H shows that $H = V^2/2g$. Thus H is the liquid head corresponding to the velocity V. Use of the velocity head to scale pressure drops has wide application in fluid mechanics. Examination of the Navier-Stokes equations suggests that when the inertial terms dominate the viscous terms, pressure gradients are expected to be proportional to ρV^2 where V is a characteristic velocity of the flow.

In the velocity head method, the losses are reported as a number of velocity heads K. Then, the engineering Bernoulli equation for an incompressible fluid can be written

$$p_1 - p_2 = \alpha_2\frac{\rho V_2^2}{2} - \alpha_1\frac{\rho V_1^2}{2} + \rho g(z_2 - z_1) + K\frac{\rho V^2}{2} \qquad (6\text{-}90)$$

where V is the reference velocity upon which the velocity head loss coefficient K is based. For a section of straight pipe, $K = 4fL/D$.

Contraction and Entrance Losses For a **sudden contraction** at a sharp-edged entrance to a pipe or sudden reduction in cross-sectional area of a channel, as shown in Fig. 6-13*a,* the loss coefficient based on the downstream velocity V_2 is given for **turbulent flow** in Crane Co. Tech Paper 410 (1980) approximately by

$$K = 0.5\left(1 - \frac{A_2}{A_1}\right) \qquad (6\text{-}91)$$

Example 5: Entrance Loss Water, ρ = 1,000 kg/m^3, flows from a large vessel through a sharp-edged entrance into a pipe at a velocity in the pipe of 2 m/s. The flow is turbulent. Estimate the pressure drop from the vessel into the pipe.

With $A_2/A_1 \sim 0$, the viscous loss coefficient is $K = 0.5$ from Eq. (6-91). The mechanical energy balance, Eq. (6-16) with $V_1 = 0$ and $z_2 - z_1 = 0$ and assuming uniform flow ($\alpha_2 = 1$) becomes

$$p_1 - p_2 = \frac{\rho V_2^2}{2} + 0.5\frac{\rho V_2^2}{2} = 4{,}000 + 2{,}000 = 6{,}000 \text{ Pa}$$

Note that the total pressure drop consists of 0.5 velocity heads of frictional loss contribution, and 1 velocity head of velocity change contribution. The frictional contribution is a permanent loss of mechanical energy by viscous dissipation. The acceleration contribution is reversible; if the fluid were subsequently decelerated in a frictionless diffuser, a 4,000 Pa pressure rise would occur.

For a **trumpet-shaped** rounded entrance, with a radius of rounding greater than about 15 percent of the pipe diameter (Fig. 6-13*b*), the turbulent flow loss coefficient K is only about 0.1 (Vennard and Street, *Elementary Fluid Mechanics,* 5th ed., Wiley, New York, 1975, pp. 420–421). Rounding of the inlet prevents formation of the **vena contracta,** thereby reducing the resistance to flow.

For **laminar flow** the losses in sudden contraction may be estimated for area ratios $A_2/A_1 < 0.2$ by an equivalent additional pipe length L_e given by

$$L_e/D = 0.3 + 0.04\text{Re} \qquad (6\text{-}92)$$

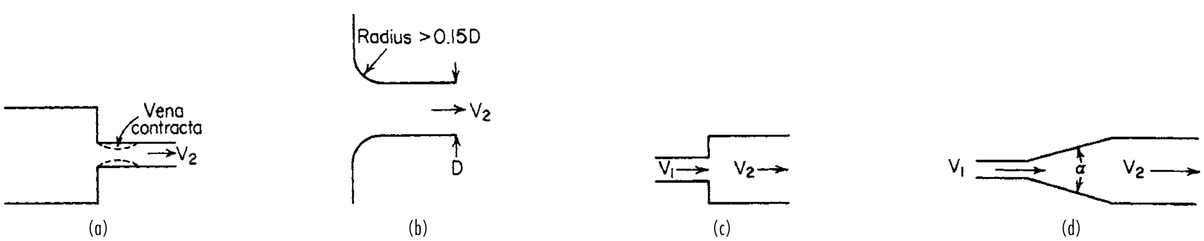

FIG. 6-13 Contractions and enlargements: (*a*) sudden contraction, (*b*) rounded contraction, (*c*) sudden enlargement, and (*d*) uniformly diverging duct.

where D is the diameter of the smaller pipe and Re is the Reynolds number in the smaller pipe. For laminar flow in the entrance to rectangular ducts, see Shah (*J. Fluids Eng.*, **100,** 177–179 [1978]) and Roscoe (*Philos. Mag.*, **40,** 338–351 [1949]). For creeping flow, Re < 1, of power law fluids, the entrance loss is approximately $L_e/D = 0.3/n$ (Boger, Gupta, and Tanner, *J. Non-Newtonian Fluid Mech.*, **4,** 239–248 [1978]). For viscoelastic fluid flow in circular channels with sudden contraction, a toroidal vortex forms upstream of the contraction plane. Such flows are reviewed by Boger (*Ann. Review Fluid Mech.*, **19,** 157–182 [1987]).

For creeping flow through **conical converging channels,** inertial acceleration terms are negligible and the viscous pressure drop $\Delta p = \rho l_v$ may be computed by integration of the differential form of the Hagen-Poiseuille equation Eq. (6-36), provided the angle of convergence is small. The result for a power law fluid is

$$\Delta p = 4K\left(\frac{3n+1}{4n}\right)^n \left(\frac{8V_2}{D_2}\right)^n \left\{\frac{1}{6n \tan(\alpha/2)}\left[1-\left(\frac{D_2}{D_1}\right)^{3n}\right]\right\} \quad (6\text{-}93)$$

where D_1 = inlet diameter
D_2 = exit diameter
V_2 = velocity at the exit
α = total included angle

Equation (6-93) agrees with experimental data (Kemblowski and Kiljanski, *Chem. Eng. J.* (*Lausanne*), **9,** 141–151 [1975]) for $\alpha < 11°$. For Newtonian liquids, Eq. (6-93) simplifies to

$$\Delta p = \mu\left(\frac{32V_2}{D_2}\right)\left\{\frac{1}{6\tan(\alpha/2)}\left[1-\left(\frac{D_2}{D_1}\right)^3\right]\right\} \quad (6\text{-}94)$$

For creeping flow through noncircular converging channels, the differential form of the Hagen-Poiseulle equation with equivalent diameter given by Eqs. (6-50) to (6-52) may be used, provided the convergence is gradual.

Expansion and Exit Losses For ducts of any cross section, the frictional loss for a **sudden enlargement** (Fig. 6-13*c*) with turbulent flow is given by the Borda-Carnot equation:

$$l_v = \frac{V_1^2 - V_2^2}{2} = \frac{V_1^2}{2}\left(1-\frac{A_1}{A_2}\right)^2 \quad (6\text{-}95)$$

where V_1 = velocity in the smaller duct
V_2 = velocity in the larger duct
A_1 = cross-sectional area of the smaller duct
A_2 = cross-sectional area of the larger duct

Equation (6-95) is valid for incompressible flow. For compressible flows, see Benedict, Wyler, Dudek, and Gleed (*J. Eng. Power,* **98,** 327–334 [1976]). For an infinite expansion, $A_1/A_2 = 0$, Eq. (6-95) shows that the **exit loss** from a pipe is 1 velocity head. This result is easily deduced from the mechanical energy balance Eq. (6-90), noting that $p_1 = p_2$. This exit loss is due to the dissipation of the discharged jet; there is no pressure drop at the exit.

For creeping Newtonian flow (Re < 1), the frictional loss due to a sudden enlargement should be obtained from the same equation for a sudden contraction (Eq. [6-92]). Note, however, that Boger, Gupta, and Tanner (ibid.) give an exit friction equivalent length of 0.12 diameter, increasing for power law fluids as the exponent decreases. For laminar flows at higher Reynolds numbers, the pressure drop is twice that given by Eq. (6-95). This results from the velocity profile factor α in the mechanical energy balance being 2.0 for the parabolic laminar velocity profile.

If the transition from a small to a large duct of any cross-sectional shape is accomplished by a **uniformly diverging duct** (see Fig. 6-13*d*) with a straight axis, the total frictional pressure drop can be computed by integrating the differential form of Eq. (6-89), $dl_v/dx = 2fV^2/D$ over the length of the expansion, provided the total angle α between the diverging walls is less than 7°. For angles between 7 and 45°, the loss coefficient may be estimated as 2.6 sin(α/2) times the loss coefficient for a sudden expansion; see Hooper (*Chem. Eng.*, Nov. 7, 1988). Gibson (*Hydraulics and Its Applications,* 5th ed., Constable, London 1952, p. 93) recommends multiplying the sudden enlargement loss by 0.13 for $5° < \alpha < 7.5°$ and by $0.0110\alpha^{1.22}$ for $7.5° < \alpha <$ 35°. For angles greater than 35 to 45°, the losses are normally considered equal to those for a sudden expansion, although in some cases the losses may be greater. Expanding flow through standard pipe reducers should be treated as sudden expansions.

Trumpet-shaped enlargements for **turbulent flow** designed for constant decrease in velocity head per unit length were found by Gibson (ibid., p. 95) to give 20 to 60 percent less frictional loss than straight taper pipes of the same length.

A special feature of expansion flows occurs when **viscoelastic** liquids are extruded through a die at a low Reynolds number. The extrudate may expand to a diameter several times greater than the die diameter, whereas for a Newtonian fluid the diameter expands only 10 percent. This phenomenon, called **die swell,** is most pronounced with short dies (Graessley, Glasscock, and Crawley, *Trans. Soc. Rheol.*, **14,** 519–544 [1970]). For velocity distribution measurements near the die exit, see Goulden and MacSporran (*J. Non-Newtonian Fluid Mech.*, **1,** 183–198 [1976]) and Whipple and Hill (*AIChE J.*, **24,** 664–671 [1978]). At high flow rates, the extrudate becomes distorted, suffering **melt fracture** at wall shear stresses greater than 10^5 N/m^2. This phenomenon is reviewed by Denn (*Ann. Review Fluid Mech.*, **22,** 13–34 [1990]). Ramamurthy (*J. Rheol.*, **30,** 337–357 [1986]) has found a dependence of apparent stick-slip behavior in melt fracture to be dependent on the material of construction of the die.

Fittings and Valves For **turbulent flow,** the frictional loss for fittings and valves can be expressed by the equivalent length or velocity head methods. As fitting size is varied, K values are relatively more constant than L_e/D values, but since fittings generally do not achieve geometric similarity between sizes, K values tend to decrease with increasing fitting size. Table 6-4 gives K values for many types of fittings and valves.

Manufacturers of valves, especially control valves, express valve capacity in terms of a flow coefficient C_v, which gives the flow rate through the valve in gal/min of water at 60°F under a pressure drop of 1 lbf/in^2. It is related to K by

$$C_v = \frac{C_1 d^2}{\sqrt{K}} \quad (6\text{-}96)$$

where C_1 is a dimensional constant equal to 29.9 and d is the diameter of the valve connections in inches.

For **laminar flow,** data for the frictional loss of valves and fittings are meager (Beck and Miller, *J. Am. Soc. Nav. Eng.*, **56,** 62–83 [1944]; Beck, ibid., **56,** 235–271, 366–388, 389–395 [1944]; De Craene, *Heat. Piping Air Cond.*, **27**[10], 90–95 [1955]; Karr and Schutz, *J. Am. Soc. Nav. Eng.*, **52,** 239–256 [1940]; and Kittredge and Rowley, *Trans. ASME,* **79,** 1759–1766 [1957]). The data of Kittredge and Rowley indicate that K is constant for Reynolds numbers above 500 to 2,000, but increases rapidly as Re decreases below 500. Typical values for K for laminar flow Reynolds numbers are shown in Table 6-5.

Methods to calculate losses for **tee and wye junctions** for dividing and combining flow are given by Miller (*Internal Flow Systems,* 2d ed., Chap. 13, BHRA, Cranfield, 1990), including effects of Reynolds number, angle between legs, area ratio, and radius. Junctions with more than three legs are also discussed. The sources of data for the loss coefficient charts are Blaisdell and Manson (*U.S. Dept. Agric. Res. Serv. Tech. Bull.* 1283 [August 1963]) for combining flow and Gardel (*Bull. Tech. Suisses Romande,* **85**[9], 123–130 [1957]; **85**[10], 143–148 [1957]) together with additional unpublished data for dividing flow.

Miller (*Internal Flow Systems,* 2d ed., Chap. 13, BHRA, Cranfield, 1990) gives the most complete information on losses in **bends and curved pipes.** For turbulent flow in circular cross-section bends of constant area, as shown in Fig. 6-14*a,* a more accurate estimate of the loss coefficient K than that given in Table 6-4 is

$$K = K^* C_{Re} C_o C_f \quad (6\text{-}97)$$

where K^*, given in Fig. 6-14*b*, is the loss coefficient for a smooth-walled bend at a Reynolds number of 10^6. The Reynolds number correction factor C_{Re} is given in Fig. 6-14*c*. For $0.7 < r/D < 1$ or for $K^* < 0.4$, use the C_{Re} value for $r/D = 1$. Otherwise, if $r/D < 1$, obtain C_{Re} from

$$C_{Re} = \frac{K^*}{K^* + 0.2(1 - C_{Re,\, r/D=1})} \quad (6\text{-}98)$$

SOURCE: From curves by Kittredge and Rowley, *Trans. Am. Soc. Mech. Eng.,* **79,** 1759–1766 (1957).

The correction C_o (Fig. 6-14*d*) accounts for the extra losses due to developing flow in the outlet tangent of the pipe, of length L_o. The total loss for the bend plus outlet pipe includes the bend loss K plus the straight pipe frictional loss in the outlet pipe $4fL_o/D$. Note that $C_o = 1$ for L_o/D greater than the termination of the curves on Fig. 6-14*d*, which indicate the distance at which fully developed flow in the outlet pipe is reached. Finally, the roughness correction is

$$C_f = \frac{f_{\text{rough}}}{f_{\text{smooth}}} \tag{6-99}$$

where f_{rough} is the friction factor for a pipe of diameter D with the roughness of the bend, at the bend inlet Reynolds number. Similarly, f_{smooth} is the friction factor for smooth pipe. For Re > 10^6 and $r/D \geq 1$, use the value of C_f for Re = 10^6.

Example 6: Losses with Fittings and Valves It is desired to calculate the liquid level in the vessel shown in Fig. 6-15 required to produce a discharge velocity of 2 m/s. The fluid is water at 20°C with $\rho = 1{,}000$ kg/m³ and $\mu = 0.001$ Pa · s, and the butterfly valve is at $\theta = 10°$. The pipe is 2-in Schedule 40, with an inner diameter of 0.0525 m. The pipe roughness is 0.046 mm. Assuming the flow is turbulent and taking the velocity profile factor $\alpha = 1$, the engineering Bernoulli equation Eq. (6-16), written between surfaces 1 and 2, where the pressures are both atmospheric and the fluid velocities are 0 and $V = 2$ m/s, respectively, and there is no shaft work, simplifies to

$$gZ = \frac{V^2}{2} + l_v$$

Contributing to l_v are losses for the entrance to the pipe, the three sections of straight pipe, the butterfly valve, and the 90° bend. Note that no exit loss is used because the discharged jet is outside the control volume. Instead, the $V^2/2$ term accounts for the kinetic energy of the discharging stream. The Reynolds number in the pipe is

$$\text{Re} = \frac{DV\rho}{\mu} = \frac{0.0525 \times 2 \times 1000}{0.001} = 1.05 \times 10^5$$

From Fig. 6-9 or Eq. (6-38), at $\epsilon/D = 0.046 \times 10^{-3}/0.0525 = 0.00088$, the friction factor is about 0.0054. The straight pipe losses are then

$$l_{v(\text{sp})} = \left(\frac{4fL}{D}\right)\frac{V^2}{2} = \left(\frac{4 \times 0.0054 \times (1+1+1)}{0.0525}\right)\frac{V^2}{2} = 1.23\,\frac{V^2}{2}$$

The losses from Table 6-4 in terms of velocity heads K are $K = 0.5$ for the sudden contraction and $K = 0.52$ for the butterfly valve. For the 90° standard radius ($r/D = 1$), the table gives $K = 0.75$. The method of Eq. (6-94), using Fig. 6-14, gives

$$K = K^* C_{\text{Re}} C_o C_f = 0.24 \times 1.24 \times 1.0 \times \left(\frac{0.0054}{0.0044}\right) = 0.37$$

This value is more accurate than the value in Table 6-4. The value $f_{\text{smooth}} = 0.0044$ is obtainable either from Eq. (6-37) or Fig. 6-9.

The total losses are then

$$l_v = (1.23 + 0.5 + 0.52 + 0.37)\,\frac{V^2}{2} = 2.62\,\frac{V^2}{2}$$

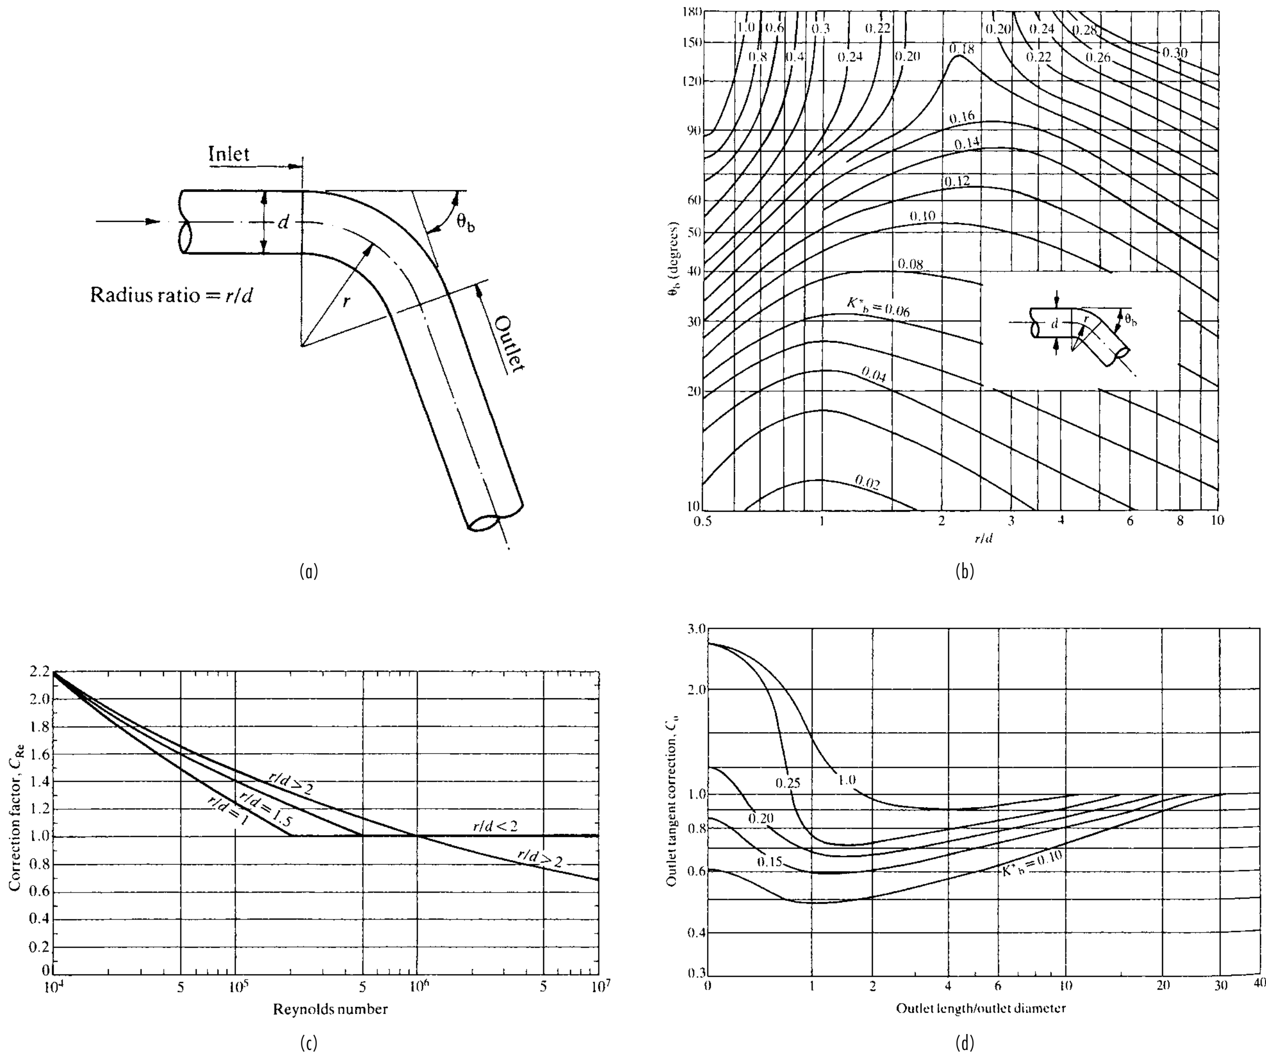

FIG. 6-14 Loss coefficients for flow in bends and curved pipes: (*a*) flow geometry, (*b*) loss coefficient for a smooth-walled bend at Re = 10^6, (*c*) Re correction factor, (*d*) outlet pipe correction factor. (*From D. S. Miller,* Internal Flow Systems, *2d ed., BHRA, Cranfield, U.K., 1990.*)

and the liquid level Z is

$$Z = \frac{1}{g}\left(\frac{V^2}{2} + 2.62\,\frac{V^2}{2}\right) = 3.62\,\frac{V^2}{2g}$$

$$= \frac{3.62 \times 2^2}{2 \times 9.81} = 0.73 \text{ m}$$

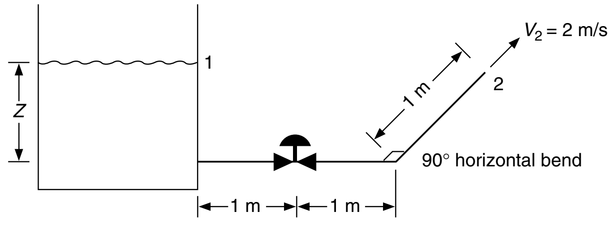

FIG. 6-15 Tank discharge example.

Curved Pipes and Coils For flow through curved pipe or coil, a secondary circulation perpendicular to the main flow called the **Dean effect** occurs. This circulation increases the friction relative to straight pipe flow and stabilizes laminar flow, delaying the transition Reynolds number to about

$$\text{Re}_{crit} = 2{,}100\left(1 + 12\sqrt{\frac{D}{D_c}}\right) \tag{6-100}$$

where D_c is the coil diameter. Equation (6-100) is valid for $10 < D_c/D < 250$. The **Dean number** is defined as

$$\text{De} = \frac{\text{Re}}{(D_c/D)^{1/2}} \tag{6-101}$$

In laminar flow, the friction factor for curved pipe f_c may be expressed in terms of the straight pipe friction factor $f = 16/\text{Re}$ as (Hart, *Chem. Eng. Sci.,* **43,** 775–783 [1988])

$$f_c/f = 1 + 0.090\left(\frac{\text{De}^{1.5}}{70 + \text{De}}\right) \tag{6-102}$$

For turbulent flow, equations by Ito (*J. Basic Eng,* **81,** 123 [1959]) and Srinivasan, Nandapurkar, and Holland (*Chem. Eng.* [*London*] no. 218, CE113-CE119 [May 1968]) may be used, with probable accuracy of ±15 percent. Their equations are similar to

$$f_c = \frac{0.079}{\text{Re}^{0.25}} + \frac{0.0073}{\sqrt{(D_c/D)}} \tag{6-103}$$

The pressure drop for flow in **spirals** is discussed by Srinivasan, et al. (loc. cit.) and Ali and Seshadri (*Ind. Eng. Chem. Process Des. Dev.,* **10,** 328–332 [1971]). For friction loss in laminar flow through **semicircular ducts,** see Masliyah and Nandakumar (*AIChE J.,* **25,** 478–487 [1979]); for curved channels of **square cross section,** see Cheng, Lin, and Ou (*J. Fluids Eng.,* **98,** 41–48 [1976]).

For **non-Newtonian** (**power law**) **fluids** in coiled tubes, Mashelkar and Devarajan (*Trans. Inst. Chem. Eng.* (*London*), **54,** 108–114 [1976]) propose the correlation

$$f_c = (9.07 - 9.44n + 4.37n^2)(D/D_c)^{0.5}(\text{De}')^{-0.768 + 0.122n} \tag{6-104}$$

where De′ is a modified Dean number given by

$$\text{De}' = \frac{1}{8}\left(\frac{6n+2}{n}\right)^n \text{Re}_{\text{MR}} \sqrt{\frac{D}{D_c}} \tag{6-105}$$

where Re_{MR} is the Metzner-Reed Reynolds number, Eq. (6-65). This correlation was tested for the range De′ = 70 to 400, D/D_c = 0.01 to 0.135, and n = 0.35 to 1. See also Oliver and Asghar (*Trans. Inst. Chem. Eng.* [*London*], **53,** 181–186 [1975]).

Screens The pressure drop for incompressible flow across a screen of fractional free area α may be computed from

$$\Delta p = K \frac{\rho V^2}{2} \tag{6-106}$$

where ρ = fluid density
V = superficial velocity based upon the gross area of the screen
K = velocity head loss

$$K = \left(\frac{1}{C^2}\right)\left(\frac{1-\alpha^2}{\alpha^2}\right) \tag{6-107}$$

The discharge coefficient for the screen C with aperture D_s is given as a function of screen Reynolds number Re = $D_s(V/\alpha)\rho/\mu$ in Fig. 6-16 for **plain square-mesh screens,** α = 0.14 to 0.79. This curve fits most of the data within ±20 percent. In the laminar flow region, Re < 20, the discharge coefficient can be computed from

$$C = 0.1\sqrt{\text{Re}} \tag{6-108}$$

Coefficients greater than 1.0 in Fig. 6-16 probably indicate partial pressure recovery downstream of the minimum aperture, due to rounding of the wires.

Grootenhuis (*Proc. Inst. Mech. Eng.* [*London*], **A168,** 837–846 [1954]) presents data which indicate that for a series of screens, the total pressure drop equals the number of screens times the pressure drop for one screen, and is not affected by the spacing between screens or their orientation with respect to one another, and presents a correlation for frictional losses across plain square-mesh screens and sintered gauzes. Armour and Cannon (*AIChE J.,* **14,** 415–420 [1968]) give a correlation based on a packed bed model for plain, twill, and "dutch" weaves. For losses through monofilament fabrics see Pedersen (*Filtr. Sep.,* **11,** 586–589 [1975]). For screens **inclined at an angle** θ, use the normal velocity component V'

$$V' = V \cos\theta \tag{6-109}$$

(Carothers and Baines, *J. Fluids Eng.,* **97,** 116–117 [1975]) in place of V in Eq. (6-106). This applies for Re > 500, C = 1.26, α ≤ 0.97, and 0 < θ < 45°, for square-mesh screens and diamond-mesh netting. Screens inclined at an angle to the flow direction also experience a tangential stress.

For **non-Newtonian** fluids in slow flow, friction loss across a square-woven or full-twill-woven screen can be estimated by considering the screen as a set of parallel tubes, each of diameter equal to the average minimal opening between adjacent wires, and length twice the diameter, without entrance effects (Carley and Smith, *Polym. Eng. Sci.,* **18,** 408–415 [1978]). For screen stacks, the losses of individual screens should be summed.

JET BEHAVIOR

A **free jet,** upon leaving an outlet, will entrain the surrounding fluid, expand, and decelerate. To a first approximation, total momentum is conserved as jet momentum is transferred to the entrained fluid. For practical purposes, a jet is considered free when its cross-sectional area is less than one-fifth of the total cross-sectional flow area of the region through which the jet is flowing (Elrod, *Heat. Piping Air Cond.,* **26**[3], 149–155 [1954]), and the surrounding fluid is the same as the jet fluid. A **turbulent jet** in this discussion is considered to be a free jet with Reynolds number greater than 2,000. Additional discussion on the relation between Reynolds number and turbulence in jets is given by Elrod (ibid.). Abramowicz (*The Theory of Turbulent Jets,* MIT Press, Cambridge, 1963) and Rajaratnam (*Turbulent Jets,* Elsevier, Amsterdam, 1976) provide thorough discourses on turbulent jets. Hussein, et al. (*J. Fluid Mech.,* **258,** 31–75 [1994]) give extensive

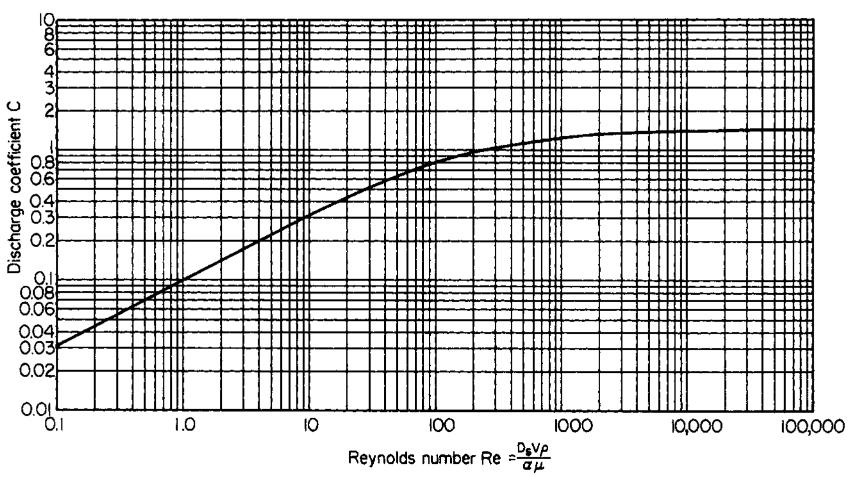

FIG. 6-16 Screen discharge coefficients, plain square-mesh screens. (*Courtesy of E. I. du Pont de Nemours & Co.*)

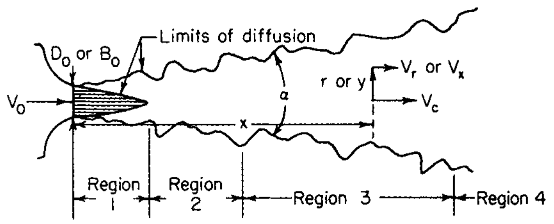

FIG. 6-17 Configuration of a turbulent free jet.

velocity data for a free jet, as well as an extensive discussion of free jet experimentation and comparison of data with momentum conservation equations.

A turbulent free jet is normally considered to consist of four flow regions (Tuve, *Heat. Piping Air Cond.*, **25**[1], 181–191 [1953]; Davies, *Turbulence Phenomena,* Academic, New York, 1972) as shown in Fig. 6-17:

1. Region of flow establishment—a short region whose length is about 6.4 nozzle diameters. The fluid in the conical core of the same length has a velocity about the same as the initial discharge velocity. The termination of this *potential core* occurs when the growing mixing or boundary layer between the jet and the surroundings reaches the centerline of the jet.
2. A transition region that extends to about 8 nozzle diameters.
3. Region of established flow—the principal region of the jet. In this region, the velocity profile transverse to the jet is self-preserving when normalized by the centerline velocity.
4. A terminal region where the residual centerline velocity reduces rapidly within a short distance. For air jets, the residual velocity will reduce to less than 0.3 m/s, (1.0 ft/s) usually considered still air.

Several references quote a length of 100 nozzle diameters for the length of the established flow region. However, this length is dependent on initial velocity and Reynolds number.

Table 6-6 gives characteristics of **rounded-inlet circular jets** and **rounded-inlet infinitely wide slot jets** (aspect ratio > 15). The information in the table is for a homogeneous, incompressible air system under isothermal conditions. The table uses the following nomenclature:

B_0 = slot height
D_0 = circular nozzle opening
q = total jet flow at distance x
q_0 = initial jet flow rate
r = radius from circular jet centerline
y = transverse distance from slot jet centerline
V_c = centerline velocity
V_r = circular jet velocity at r
V_y = velocity at y

Witze (*Am. Inst. Aeronaut. Astronaut. J.*, **12,** 417–418 [1974]) gives equations for the centerline velocity decay of different types of subsonic and supersonic circular free jets. Entrainment of surrounding fluid in the region of flow establishment is lower than in the region of established flow (see Hill, *J. Fluid Mech.*, **51,** 773–779 [1972]). Data of Donald and Singer (*Trans. Inst. Chem. Eng.* [*London*], **37,** 255–267 [1959]) indicate that jet angle and the coefficients given in Table 6-6 depend upon the fluids; for a water system, the jet angle for a circular jet is 14° and the entrainment ratio is about 70 percent of that for an air system. Most likely these variations are due to Reynolds number effects which are not taken into account in Table 6-6. Rushton (*AIChE J.*, **26,** 1038–1041 [1980]) examined available published results for circular jets and found that the centerline velocity decay is given by

$$\frac{V_c}{V_0} = 1.41\text{Re}^{0.135}\left(\frac{D_0}{x}\right) \qquad (6\text{-}110)$$

where $\text{Re} = D_0V_0\rho/\mu$ is the initial jet Reynolds number. This result corresponds to a jet angle $\tan \alpha/2$ proportional to $\text{Re}^{-0.135}$.

TABLE 6-6 Turbulent Free-Jet Characteristics

Where both jet fluid and entrained fluid are air

Rounded-inlet, infinitely wide slot jet

Longitudinal distribution of velocity along jet centerline‡

$$\frac{V_c}{V_0} = 2.28\left(\frac{B_0}{x}\right)^{0.5} \qquad \text{for } 5 < \frac{x}{B_0} < 2{,}000 \text{ and } V_0 = 12 \text{ to } 55 \text{ m/s}$$

Transverse distribution of longitudinal velocity‡

$$\log\left(\frac{V_c}{V_x}\right) = 18.4\left(\frac{y}{x}\right)^2 \qquad \text{for } 5 < \frac{x}{B_0} < 2{,}000$$

Jet angle‡

α is slightly larger than that for a circular jet

Entrainment of surrounding fluid‡

$$\frac{q}{q_0} = 0.62\left(\frac{x}{B_0}\right)^{0.5} \qquad \text{for } 5 < \frac{x}{B_0} < 2{,}000$$

*Nottage, Slaby, and Gojsza, *Heat, Piping Air Cond.,* **24**(1), 165–176 (1952).
†Tuve, *Heat, Piping Air Cond.,* **25**(1), 181–191 (1953).
‡Albertson, Dai, Jensen, and Rouse, *Trans. Am. Soc. Civ. Eng.,* **115,** 639–664 (1950), and Discussion, ibid., **115,** 665–697 (1950).

Characteristics of **rectangular jets** of various aspect ratios are given by Elrod (*Heat., Piping, Air Cond.*, **26**[3], 149–155 [1954]). For **slot jets discharging into a moving fluid,** see Weinstein, Osterle, and Forstall (*J. Appl. Mech.,* **23,** 437–443 [1967]). **Coaxial jets** are discussed by Forstall and Shapiro (*J. Appl. Mech.,* **17,** 399–408 [1950]), and **double concentric jets** by Chigier and Beer (*J. Basic Eng.,* **86,** 797–804 [1964]). **Axisymmetric confined jets** are described by Barchilon and Curtet (*J. Basic Eng.,* **777–787** [1964]). **Restrained** turbulent jets of liquid discharging into air are described by Davies (*Turbulence Phenomena,* Academic, New York, 1972). These jets are inherently unstable and break up into drops after some distance. Lienhard and Day (*J. Basic Eng. Trans. AIME,* p. 515 [September 1970]) discuss the breakup of superheated liquid jets which flash upon discharge.

Density gradients affect the spread of a single-phase jet. A jet of lower density than the surroundings spreads more rapidly than a jet of the same density as the surroundings, and, conversely, a denser jet spreads less rapidly. Additional details are given by Keagy and Weller (*Proc. Heat Transfer Fluid Mech. Inst., ASME,* pp. 89–98, June 22–24 [1949]) and Cleeves and Boelter (*Chem. Eng. Prog.,* **43,** 123–134 [1947]).

Few experimental data exist on **laminar jets** (see Gutfinger and Shinnar, *AIChE J.,* **10,** 631–639 [1964]). Theoretical analysis for velocity distributions and entrainment ratios are available in Schlichting and in Morton (*Phys. Fluids,* **10,** 2120–2127 [1967]).

Theoretical analyses of jet flows for power law **non-Newtonian fluids** are given by Vlachopoulos and Stournaras (*AIChE J.,* **21,** 385–388 [1975]), Mitwally (*J. Fluids Eng.,* **100,** 363 [1978]), and Sridhar and Rankin (*J. Fluids Eng.,* **100,** 500 [1978]).

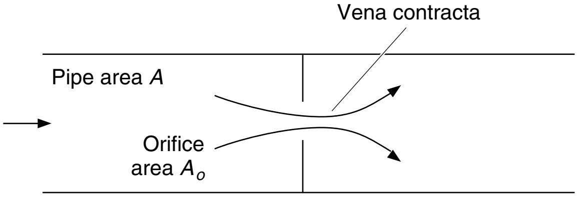

FIG. 6-18 Flow through an orifice.

FLOW THROUGH ORIFICES

Section 10 of this *Handbook* describes the use of orifice meters for flow measurement. In addition, **orifices** are commonly found within pipelines as flow-restricting devices, in perforated pipe distributing and return manifolds, and in perforated plates. Incompressible flow through an orifice in a pipeline, as shown in Fig. 6-18, is commonly described by the following equation for flow rate Q in terms of the pressures P_1, P_2, and P_3; the orifice area A_o; the pipe cross-sectional area A; and the density ρ.

$$Q = v_o A_o = C_o A_o \sqrt{\frac{2(P_1 - P_2)}{\rho[1 - (A_o/A)^2]}}$$

$$= C_o A_o \sqrt{\frac{2(P_1 - P_3)}{\rho(1 - A_o/A)\,[1 - (A_o/A)^2]}} \qquad (6\text{-}111)$$

The velocity based on the hole area is v_o. The pressure P_1 is the pressure upstream of the orifice, typically about 1 pipe diameter upstream, the pressure P_2 is the pressure at the **vena contracta,** where the flow passes through a minimum area which is less than the orifice area, and the pressure P_3 is the pressure downstream of the vena contracta after pressure recovery associated with deceleration of the fluid. The velocity of approach factor $1 - (A_o/A)^2$ accounts for the kinetic energy approaching the orifice, and the **orifice coefficient** or **discharge coefficient** C_o accounts for the vena contracta. The location of the vena contracta varies with A_0/A, but is about 0.7 pipe diameter for $A_o/A < 0.25$. The factor $1 - A_o/A$ accounts for pressure recovery. Pressure recovery is complete by about 4 to 8 pipe diameters downstream of the orifice. The permanent pressure drop is $P_1 - P_3$. When the orifice is at the end of pipe, discharging directly into a large chamber, there is negligible pressure recovery, the permanent pressure drop is $P_1 - P_2$, and the last equality in Eq. (6-111) does not apply. Instead, $P_2 = P_3$. Equation (6-111) may also be used for flow across a perforated plate with open area A_o and total area A. The location of the vena contracta and complete recovery would scale not with the vessel or pipe diameter in which the plate is installed, but with the hole diameter and pitch between holes.

The orifice coefficient has a value of about 0.62 at large Reynolds numbers ($\text{Re} = D_o V_o \rho/\mu > 20{,}000$), although values ranging from 0.60 to 0.70 are frequently used. At lower Reynolds numbers, the orifice coefficient varies with both Re and with the area or diameter ratio. See Sec. 10 for more details.

When liquids discharge vertically downward from a pipe of diameter D_p, through orifices into gas, gravity increases the discharge coefficient. Figure 6-19 shows this effect, giving the discharge coefficient in terms of a modified Froude number, $\text{Fr} = \Delta p/(\rho g D_p)$.

The orifice coefficient deviates from its value for sharp-edged orifices when the orifice wall thickness exceeds about 75 percent of the orifice diameter. Some pressure recovery occurs within the orifice and the orifice coefficient increases. Pressure drop across **segmental orifices** is roughly 10 percent greater than that for concentric circular orifices of the same open area.

COMPRESSIBLE FLOW

Flows are typically considered **compressible** when the density varies by more than 5 to 10 percent. In practice compressible flows are normally limited to gases, supercritical fluids, and multiphase flows

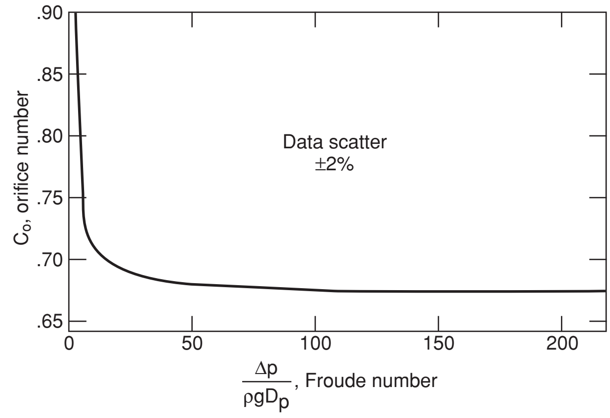

FIG. 6-19 Orifice coefficient vs. Froude number. (*Courtesy E. I. duPont de Nemours & Co.*)

containing gases. Liquid flows are normally considered incompressible, except for certain calculations involved in **hydraulic transient** analysis (see following) where compressibility effects are important even for nearly incompressible liquids with extremely small density variations. Textbooks on compressible gas flow include Shapiro (*Dynamics and Thermodynamics of Compressible Fluid Flow,* vols. I and II, Ronald Press, New York [1953]) and Zucrow and Hofmann (*Gas Dynamics,* vols. I and II, Wiley, New York [1976]).

In chemical process applications, one-dimensional gas flows through nozzles or orifices and in pipelines are the most important applications of compressible flow. Multidimensional external flows are of interest mainly in aerodynamic applications.

Mach Number and Speed of Sound The **Mach number** $M = V/c$ is the ratio of fluid velocity, V, to the **speed of sound** or **acoustic velocity,** c. The speed of sound is the propagation velocity of infinitesimal pressure disturbances and is derived from a momentum balance. The compression caused by the pressure wave is adiabatic and frictionless, and therefore isentropic.

$$c = \sqrt{\left(\frac{\partial p}{\partial \rho}\right)_s} \qquad (6\text{-}112)$$

The derivative of pressure p with respect to density ρ is taken at constant entropy s. For an ideal gas,

$$\left(\frac{\partial p}{\partial \rho}\right)_s = \frac{kRT}{M_w}$$

where k = ratio of specific heats, C_p/C_v
R = universal gas constant (8,314 J/kgmol K)
T = absolute temperature
M_w = molecular weight

Hence for an ideal gas,

$$c = \sqrt{\frac{kRT}{M_w}} \qquad (6\text{-}113)$$

Most often, the Mach number is calculated using the speed of sound evaluated at the local pressure and temperature. When $M = 1$, the flow is **critical** or **sonic** and the velocity equals the local speed of sound. For **subsonic** flow $M < 1$ while **supersonic** flows have $M > 1$. Compressibility effects are important when the Mach number exceeds 0.1 to 0.2. A common error is to assume that compressibility effects are always negligible when the Mach number is small. The proper assessment of whether compressibility is important should be based on relative density changes, not on Mach number.

Isothermal Gas Flow in Pipes and Channels Isothermal compressible flow is often encountered in long transport lines, where there is sufficient heat transfer to maintain constant temperature. Velocities and Mach numbers are usually small, yet compressibility

effects are important when the total pressure drop is a large fraction of the absolute pressure. For an ideal gas with $\rho = pM_w/RT$, integration of the differential form of the momentum or mechanical energy balance equations, assuming a constant friction factor f over a length L of a channel of constant cross section and hydraulic diameter D_H, yields,

$$p_1^2 - p_2^2 = G^2 \frac{RT}{M_w}\left[\frac{4fL}{D_H} + 2\ln\left(\frac{p_1}{p_2}\right)\right] \quad (6\text{-}114)$$

where the mass velocity $G = w/A = \rho V$ is the mass flow rate per unit cross-sectional area of the channel. The logarithmic term on the right-hand side accounts for the pressure change caused by acceleration of gas as its density decreases, while the first term is equivalent to the calculation of frictional losses using the density evaluated at the average pressure $(p_1 + p_2)/2$.

Solution of Eq. (6-114) for G and differentiation with respect to p_2 reveals a maximum mass flux $G_{max} = p_2\sqrt{M_w/(RT)}$ and a corresponding exit velocity $V_{2,max} = \sqrt{RT/M_w}$ and exit Mach number $M_2 = 1/\sqrt{k}$. This apparent **choking** condition, though often cited, is not physically meaningful for isothermal flow because at such high velocities, and high rates of expansion, isothermal conditions are not maintained.

Adiabatic Frictionless Nozzle Flow In process plant pipelines, compressible flows are usually more nearly adiabatic than isothermal. Solutions for adiabatic flows through frictionless nozzles and in channels with constant cross section and constant friction factor are readily available.

Figure 6-20 illustrates adiabatic discharge of a **perfect** gas through a frictionless nozzle from a large chamber where velocity is effectively zero. A perfect gas obeys the ideal gas law $\rho = pM_w/RT$ and also has constant specific heat. The subscript 0 refers to the **stagnation** conditions in the chamber. More generally, stagnation conditions refer to the conditions which would be obtained by isentropically decelerating a gas flow to zero velocity. The minimum area section, or *throat,* of the nozzle is at the nozzle exit. The flow through the nozzle is isentropic because it is frictionless (reversible) and adiabatic. In terms of the exit Mach number M_1 and the upstream stagnation conditions, the flow conditions at the nozzle exit are given by

$$\frac{p_0}{p_1} = \left(1 + \frac{k-1}{2} M_1^2\right)^{k/(k-1)} \quad (6\text{-}115)$$

$$\frac{T_0}{T_1} = 1 + \frac{k-1}{2} M_1^2 \quad (6\text{-}116)$$

$$\frac{\rho_0}{\rho_1} = \left(1 + \frac{k-1}{2} M_1^2\right)^{1/(k-1)} \quad (6\text{-}117)$$

The mass velocity $G = w/A$, where w is the mass flow rate and A is the nozzle exit area, at the nozzle exit is given by

$$G = p_0 \sqrt{\frac{kM_w}{RT_0}} \frac{M_1}{\left(1 + \dfrac{k-1}{2} M_1^2\right)^{(k+1)/2(k-1)}} \quad (6\text{-}118)$$

These equations are consistent with the isentropic relations for a perfect gas $p/p_0 = (\rho/\rho_0)^k$, $T/T_0 = (p/p_0)^{(k-1)/k}$. Equation (6-116) is valid for adiabatic flows with or without friction; it does not require isentropic flow. However, Eqs. (6-115) and (6-117) do require isentropic flow.

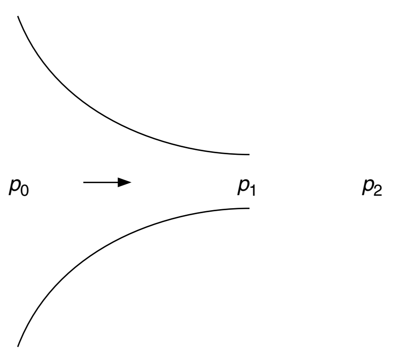

FIG. 6-20 Isentropic flow through a nozzle.

The exit Mach number M_1 may not exceed unity. At $M_1 = 1$, the flow is said to be **choked, sonic,** or **critical.** When the flow is choked, the pressure at the exit is greater than the pressure of the surroundings into which the gas flow discharges. The pressure drops from the exit pressure to the pressure of the surroundings in a series of shocks which are highly nonisentropic. Sonic flow conditions are denoted by *; sonic exit conditions are found by substituting $M_1 = M_1^* = 1$ into Eqs. (6-115) to (6-118).

$$\frac{p^*}{p_0} = \left(\frac{2}{k+1}\right)^{k/(k-1)} \quad (6\text{-}119)$$

$$\frac{T^*}{T_0} = \frac{2}{k+1} \quad (6\text{-}120)$$

$$\frac{\rho^*}{\rho_0} = \left(\frac{2}{k+1}\right)^{1/(k-1)} \quad (6\text{-}121)$$

$$G^* = p_0 \sqrt{\left(\frac{2}{k+1}\right)^{(k+1)/(k-1)} \left(\frac{kM_w}{RT_0}\right)} \quad (6\text{-}122)$$

Note that under choked conditions, the exit velocity is $V = V^* = c^* = \sqrt{kRT^*/M_w}$, not $\sqrt{kRT_0/M_w}$. Sonic velocity must be evaluated at the exit temperature. For air, with $k = 1.4$, the critical pressure ratio p^*/p_0 is 0.5285 and the critical temperature ratio $T^*/T_0 = 0.8333$. Thus, for air discharging from 300 K, the temperature drops by 50 K (90 R). This large temperature decrease results from the conversion of internal energy into kinetic energy and is reversible. As the discharged jet decelerates in the external stagant gas, it recovers its initial enthalpy.

When it is desired to determine the discharge rate through a nozzle from upstream pressure p_0 to external pressure p_2, Equations (6-115) through (6-122) are best used as follows. The critical pressure is first determined from Eq. (6-119). If $p_2 > p^*$, then the flow is subsonic (subcritical, unchoked). Then $p_1 = p_2$ and M_1 may be obtained from Eq. (6-115). Substitution of M_1 into Eq. (6-118) then gives the desired mass velocity G. Equations (6-116) and (6-117) may be used to find the exit temperature and density. On the other hand, if $p_2 \le p^*$, then the flow is choked and $M_1 = 1$. Then $p_1 = p^*$, and the mass velocity is G^* obtained from Eq. (6-122). The exit temperature and density may be obtained from Eqs. (6-120) and (6-121).

When the flow is choked, $G = G^*$ is independent of external downstream pressure. Reducing the downstream pressure will not increase the flow. The mass flow rate under choking conditions is directly proportional to the upstream pressure.

Example 7: Flow through Frictionless Nozzle Air at p_0 and temperature $T_0 = 293$ K discharges through a frictionless nozzle to atmospheric pressure. Compute the discharge mass flux G, the pressure, temperature, Mach number, and velocity at the exit. Consider two cases: (1) $p_0 = 7 \times 10^5$ Pa absolute, and (2) $p_0 = 1.5 \times 10^5$ Pa absolute.

1. $p_0 = 7.0 \times 10^5$ Pa. For air with $k = 1.4$, the critical pressure ratio from Eq. (6-119) is $p^*/p_0 = 0.5285$ and $p^* = 0.5285 \times 7.0 \times 10^5 = 3.70 \times 10^5$ Pa. Since this is greater than the external atmospheric pressure $p_2 = 1.01 \times 10^5$ Pa, the flow is choked and the exit pressure is $p_1 = 3.70 \times 10^5$ Pa. The exit Mach number is 1.0, and the mass flux is equal to G^* given by Eq. (6-118).

$$G^* = 7.0 \times 10^5 \times \sqrt{\left(\frac{2}{1.4+1}\right)^{(1.4+1)/(1.4-1)} \left(\frac{1.4 \times 29}{8314 \times 293}\right)} = 1{,}650 \text{ kg/m}^2 \cdot \text{s}$$

The exit temperature, since the flow is choked, is

$$T^* = \left(\frac{T^*}{T_0}\right)T_0 = \left(\frac{2}{1.4+1}\right) \times 293 = 244 \text{ K}$$

The exit velocity is $V = Mc = c^* = \sqrt{kRT^*/M_w} = 313$ m/s.

2. $p_0 = 1.5 \times 10^5$ Pa. In this case $p^* = 0.79 \times 10^5$ Pa, which is less than p_2. Hence, $p_1 = p_2 = 1.01 \times 10^5$ Pa. The flow is unchoked (subsonic). Equation (6-115) is solved for the Mach number.

$$\frac{1.5 \times 10^5}{1.01 \times 10^5} = \left(1 + \frac{1.4-1}{2} M_1^2\right)^{1.4/(1.4-1)}$$

$$M_1 = 0.773$$

Substitution into Eq. (6-118) gives G.

$$G = 1.5 \times 10^5 \times \sqrt{\frac{1.4 \times 29}{8{,}314 \times 293}} \times \frac{0.773}{\left(1 + \left(\frac{1.4 - 1}{2}\right) \times 0.773^2\right)^{(1.4+1)/2(1.4-1)}} = 337 \text{ kg/m}^2 \cdot \text{s}$$

The exit temperature is found from Eq. (6-116) to be 261.6 K or −11.5°C. The exit velocity is

$$V = Mc = 0.773 \times \sqrt{\frac{1.4 \times 8314 \times 261.6}{29}} = 250 \text{ m/s}$$

Adiabatic Flow with Friction in a Duct of Constant Cross Section Integration of the differential forms of the continuity, momentum, and total energy equations for a perfect gas, assuming a constant friction factor, leads to a tedious set of simultaneous algebraic equations. These may be found in Shapiro (*Dynamics and Thermodynamics of Compressible Fluid Flow,* vol. I, Ronald Press, New York, 1953) or Zucrow and Hofmann (*Gas Dynamics,* vol. I, Wiley, New York, 1976). Lapple's (*Trans. AIChE.,* **39,** 395–432 [1943]) widely cited graphical presentation of the solution of these equations contained a subtle error, which was corrected by Levenspiel (*AIChE J.,* **23,** 402–403 [1977]). Levenspiel's graphical solutions are presented in Fig. 6-21. These charts refer to the physical situation illustrated in Fig. 6-22, where a perfect gas discharges from stagnation conditions in a large chamber through an isentropic nozzle followed by a duct of length L. The resistance parameter is $N = 4fL/D_H$, where f = Fanning friction factor and D_H = hydraulic diameter.

The exit Mach number M_2 may not exceed unity. $M_2 = 1$ corresponds to choked flow; sonic conditions may exist only at the pipe exit. The mass velocity G^* in the charts is the choked **mass flux for an isentropic nozzle** given by Eq. (6-118). For a pipe of finite length, the mass flux is less than G^* under choking conditions. The curves in Fig. 6-21 become vertical at the choking point, where flow becomes independent of downstream pressure.

The equations for nozzle flow, Eqs. (6-114) through (6-118), remain valid for the nozzle section even in the presence of the discharge pipe. Equations (6-116) and (6-120), for the temperature variation, may also be used for the pipe, with M_2, p_2 replacing M_1, p_1 since they are valid for adiabatic flow, with or without friction.

The graphs in Fig. 6-21 are based on accurate calculations, but are difficult to interpolate precisely. While they are quite useful for rough estimates, precise calculations are best done using the equations for one-dimensional adiabatic flow with friction, which are suitable for computer programming. Let subscripts 1 and 2 denote two points along a pipe of diameter D, point 2 being downstream of point 1. From a given point in the pipe, where the Mach number is M, the additional length of pipe required to accelerate the flow to sonic velocity ($M = 1$) is denoted L_{max} and may be computed from

$$\frac{4fL_{max}}{D} = \frac{1 - M^2}{kM^2} + \frac{k+1}{2k} \ln \left(\frac{\frac{k+1}{2} M^2}{1 + \frac{k-1}{2} M^2} \right) \tag{6-123}$$

With L = length of pipe between points 1 and 2, the change in Mach number may be computed from

$$\frac{4fL}{D} = \left(\frac{4fL_{max}}{D}\right)_1 - \left(\frac{4fL_{max}}{D}\right)_2 \tag{6-124}$$

Equations (6-116) and (6-113), which are valid for adiabatic flow with friction, may be used to determine the temperature and speed of sound at points 1 and 2. Since the mass flux $G = \rho v = \rho c M$ is constant, and $\rho = PM_w/RT$, the pressure at point 2 (or 1) can be found from G and the pressure at point 1 (or 2).

The additional frictional losses due to pipeline fittings such as elbows may be added to the velocity head loss $N = 4fL/D_H$ using the same velocity head loss values as for incompressible flow. This works well for fittings which do not significantly reduce the channel cross-sectional area, but may cause large errors when the flow area is greatly reduced, as, for example, by restricting orifices. Compressible flow across restricting orifices is discussed in Sec. 10 of this *Handbook.* Similarly, elbows near the exit of a pipeline may choke the flow even though the Mach number is less than unity due to the nonuniform velocity profile in the elbow. For an abrupt contraction rather than rounded nozzle inlet, an additional 0.5 velocity head should be added to N. This is a reasonable approximation for G, but note that it allocates the additional losses to the pipeline, even though they are actually incurred in the entrance. It is an error to include one velocity head exit loss in N. The kinetic energy at the exit is already accounted for in the integration of the balance equations.

Example 8: Compressible Flow with Friction Losses Calculate the discharge rate of air to the atmosphere from a reservoir at 10^6 Pa gauge and 20°C through 10 m of straight 2-in Schedule 40 steel pipe (inside diameter = 0.0525 m), and 3 standard radius, flanged 90° elbows. Assume 0.5 velocity heads lost for the elbows.

For commercial steel pipe, with a roughness of 0.046 mm, the friction factor for fully rough flow is about 0.0047, from Eq. (6-38) or Fig. 6-9. It remains to be verified that the Reynolds number is sufficiently large to assume fully rough flow. Assuming an abrupt entrance with 0.5 velocity heads lost,

$$N = 4 \times 0.0047 \times \frac{10}{0.0525} + 0.5 + 3 \times 0.5 = 5.6$$

The pressure ratio p_3/p_0 is

$$\frac{1.01 \times 10^5}{(1 \times 10^6 + 1.01 \times 10^5)} = 0.092$$

From Fig. 6-21b at $N = 5.6$, $p_3/p_0 = 0.092$ and $k = 1.4$ for air, the flow is seen to be choked. At the choke point with $N = 5.6$ the critical pressure ratio p_2/p_0 is about 0.25 and G/G^* is about 0.48. Equation (6-122) gives

$$G^* = 1.101 \times 10^6 \times \sqrt{\left(\frac{2}{1.4+1}\right)^{(1.4+1)/(1.4-1)} \left(\frac{1.4 \times 29}{8{,}314 \times 293.15}\right)} = 2{,}600 \text{ kg/m}^2 \cdot \text{s}$$

Multiplying by $G/G^* = 0.48$ yields $G = 1{,}250$ kg/m$^2 \cdot$ s. The discharge rate is $w = GA = 1{,}250 \times \pi \times 0.0525^2/4 = 2.7$ kg/s.

Before accepting this solution, the Reynolds number should be checked. At the pipe exit, the temperature is given by Eq. (6-120) since the flow is choked. Thus, $T_2 = T^* = 244.6$ K. The viscosity of air at this temperature is about 1.6×10^{-5} Pa · s. Then

$$\text{Re} = \frac{DV\rho}{\mu} = \frac{DG}{\mu} = \frac{0.0525 \times 1{,}250}{1.6 \times 10^{-5}} = 4.1 \times 10^6$$

At the beginning of the pipe, the temperature is greater, giving greater viscosity and a Reynolds number of 3.6×10^6. Over the entire pipe length the Reynolds number is very large and the fully rough flow friction factor choice was indeed valid.

Once the mass flux G has been determined, Fig. 6-21a or 6-21b can be used to determine the pressure at any point along the pipe, simply by reducing $4fL/D_H$ and computing p_2 from the figures, given G, instead of the reverse. Charts for calculation between two points in a pipe with known flow and known pressure at either upstream or downstream locations have been presented by Loeb (*Chem. Eng.,* **76**[5], 179–184 [1969]) and for known downstream conditions by Powley (*Can. J. Chem. Eng.,* **36,** 241–245 [1958]).

Convergent/Divergent Nozzles (De Laval Nozzles) During frictionless adiabatic one-dimensional flow with changing cross-sectional area A the following relations are obeyed:

$$\frac{dA}{A} = \frac{dp}{\rho V^2}(1 - M^2) = \frac{1 - M^2}{M^2}\frac{d\rho}{\rho} = -(1 - M^2)\frac{dV}{V} \tag{6-125}$$

Equation (6-125) implies that in converging channels, subsonic flows are accelerated and the pressure and density decrease. In diverging channels, subsonic flows are decelerated as the pressure and density increase. In subsonic flow, the converging channels act as nozzles and diverging channels as diffusers. In supersonic flows, the opposite is true. Diverging channels act as nozzles accelerating the flow, while converging channels act as diffusers decelerating the flow.

Figure 6-23 shows a converging/diverging nozzle. When p_2/p_0 is less than the critical pressure ratio (p^*/p_0), the flow will be subsonic in the converging portion of the nozzle, sonic at the throat, and supersonic in the diverging portion. At the throat, where the flow is critical and the velocity is sonic, the area is denoted A^*. The cross-sectional

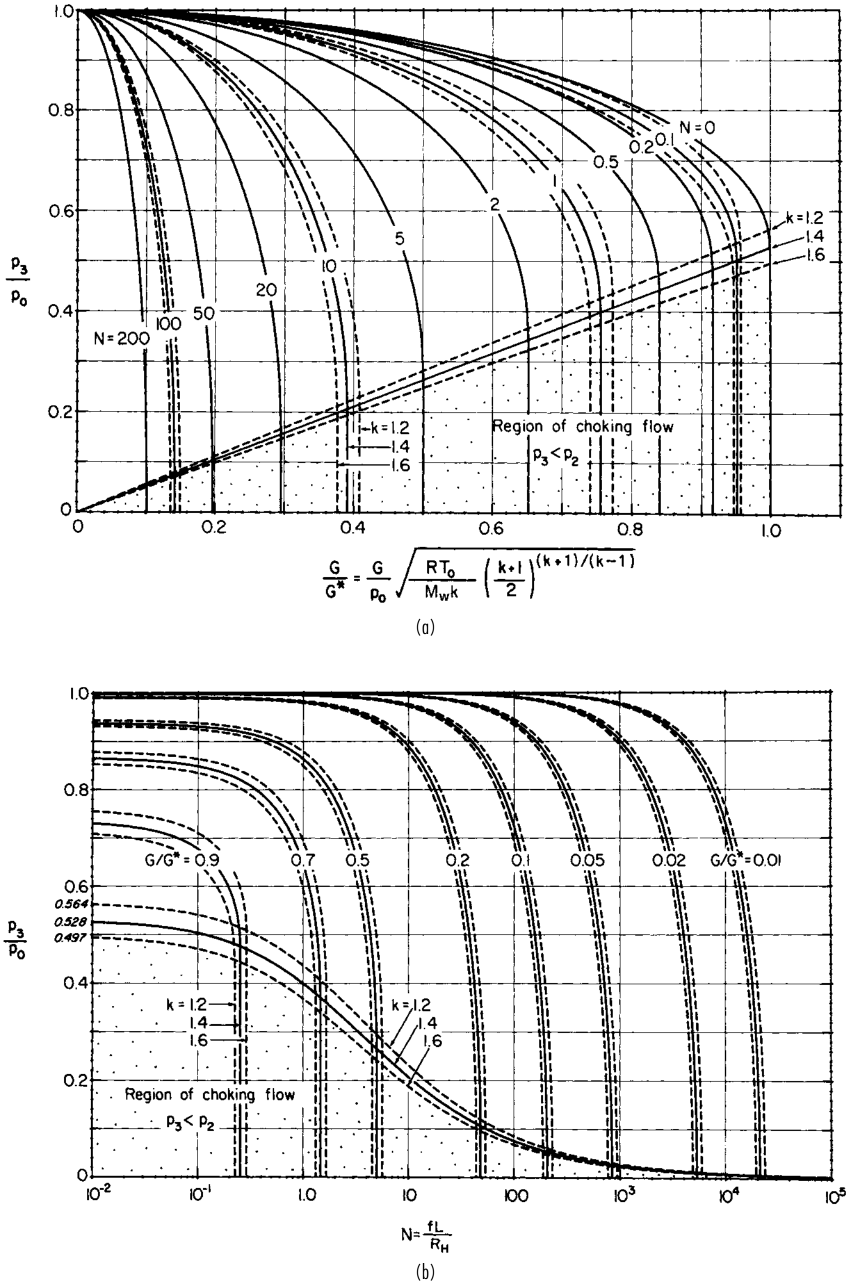

FIG. 6-21 Design charts for adiabatic flow of gases; (*a*) useful for finding the allowable pipe length for given flow rate; (*b*) useful for finding the discharge rate in a given piping system. (*From Levenspiel,* Am. Inst. Chem. Eng. J., ***23,*** *402* [*1977*].)

area and pressure vary with Mach number along the converging/diverging flow path according to the following equations for isentropic flow of a perfect gas:

$$\frac{A}{A^*} = \frac{1}{M}\left[\frac{2}{k+1}\left(1 + \frac{k-1}{2}M^2\right)\right]^{(k+1)/2(k-1)} \tag{6-126}$$

$$\frac{p_0}{p} = \left(1 + \frac{k-1}{2}M^2\right)^{k/(k-1)} \tag{6-127}$$

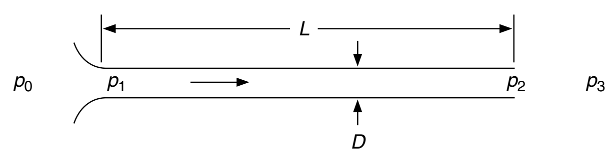

FIG. 6-22 Adiabatic compressible flow in a pipe with a well-rounded entrance.

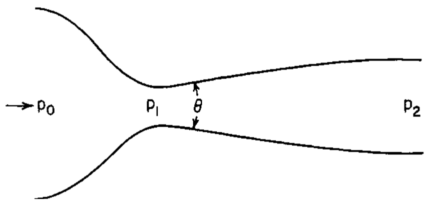

FIG. 6-23 Converging/diverging nozzle.

The temperature obeys the adiabatic flow equation for a perfect gas,

$$\frac{T_0}{T} = 1 + \frac{k-1}{2} M^2 \tag{6-128}$$

Equation (6-128) does not require frictionless (isentropic) flow. The sonic mass flux through the throat is given by Eq. (6-122). With A set equal to the nozzle exit area, the exit Mach number, pressure, and temperature may be calculated. Only if the exit pressure equals the ambient discharge pressure is the ultimate expansion velocity reached in the nozzle. Expansion will be incomplete if the exit pressure exceeds the ambient discharge pressure; shocks will occur outside the nozzle. If the calculated exit pressure is less than the ambient discharge pressure, the nozzle is overexpanded and compression shocks within the expanding portion will result.

The shape of the converging section is a smooth trumpet shape similar to the simple converging nozzle. However, special shapes of the diverging section are required to produce the maximum supersonic exit velocity. Shocks result if the divergence is too rapid and excessive boundary layer friction occurs if the divergence is too shallow. See Liepmann and Roshko (*Elements of Gas Dynamics,* Wiley, New York, 1957, p. 284). If the nozzle is to be used as a thrust device, the diverging section can be conical with a total included angle of 30° (Sutton, *Rocket Propulsion Elements,* 2d ed., Wiley, New York, 1956). To obtain large exit Mach numbers, slot-shaped rather than axisymmetric nozzles are used.

MULTIPHASE FLOW

Multiphase flows, even when restricted to simple pipeline geometry, are in general quite complex, and several features may be identified which make them more complicated than single-phase flow. Flow pattern description is not merely an identification of laminar or turbulent flow. The relative quantities of the phases and the topology of the interfaces must be described. Because of phase density differences, vertical flow patterns are different from horizontal flow patterns, and horizontal flows are not generally axisymmetric. Even when phase equilibrium is achieved by good mixing in two-phase flow, the changing equilibrium state as pressure drops with distance, or as heat is added or lost, may require that interphase mass transfer, and changes in the relative amounts of the phases, be considered.

Wallis (*One-dimensional Two-phase Flow,* McGraw-Hill, New York, 1969) and Govier and Aziz present mass, momentum, mechanical energy, and total energy balance equations for two-phase flows. These equations are based on one-dimensional behavior for each phase. Such equations, for the most part, are used as a framework in which to interpret experimental data. Reliable prediction of multiphase flow behavior generally requires use of data or correlations. **Two-fluid modeling,** in which the full three-dimensional microscopic (partial differential) equations of motion are written for each phase, treating each as a continuum, occupying a volume fraction which is a continuous function of position, is a rapidly developing technique made possible by improved computational methods. For some relatively simple examples not requiring numerical computation, see Pearson (*Chem. Engr. Sci.,* **49,** 727–732 [1994]). Constitutive equations for two-fluid models are not yet sufficiently robust for accurate general-purpose two-phase flow computation, but may be quite good for particular classes of flows.

Liquids and Gases For cocurrent flow of liquids and gases in vertical (upflow), horizontal, and inclined pipes, a very large literature of experimental and theoretical work has been published, with less work on countercurrent and cocurrent vertical downflow. Much of the effort has been devoted to predicting flow patterns, pressure drop, and volume fractions of the phases, with emphasis on fully developed flow. In practice, many two-phase flows in process plants are not fully developed.

The most reliable methods for fully developed gas/liquid flows use **mechanistic models** to predict flow pattern, and use different pressure drop and void fraction estimation procedures for each flow pattern. Such methods are too lengthy to include here, and are well suited to incorporation into computer programs; commercial codes for gas/liquid pipeline flows are available. Some key references for mechanistic methods for flow pattern transitions and flow regime–specific pressure drop and void fraction methods include Taitel and Dukler (*AIChE J.,* **22,** 47–55 [1976]), Barnea, et al. (*Int. J. Multiphase Flow,* **6,** 217–225 [1980]), Barnea (*Int. J. Multiphase Flow,* **12,** 733–744 [1986]), Taitel, Barnea, and Dukler (*AIChE J.,* **26,** 345–354 [1980]), Wallis (*One-dimensional Two-phase Flow,* McGraw-Hill, New York, 1969), and Dukler and Hubbard (*Ind. Eng. Chem. Fundam.,* **14,** 337–347 [1975]). For preliminary or approximate calculations, **flow pattern maps** and flow regime–independent empirical correlations, are simpler and faster to use. Such methods for horizontal and vertical flows are provided in the following.

In **horizontal pipe,** flow patterns for fully developed flow have been reported in numerous studies. Transitions between flow patterns are gradual, and subjective owing to the visual interpretation of individual investigators. In some cases, statistical analysis of pressure fluctuations has been used to distinguish flow patterns. Figure 6-24 (Alves, *Chem. Eng. Progr.,* **50,** 449–456 [1954]) shows seven flow patterns for horizontal gas/liquid flow. **Bubble flow** is prevalent at high ratios of liquid to gas flow rates. The gas is dispersed as bubbles which move at velocity similar to the liquid and tend to concentrate near the top of the pipe at lower liquid velocities. **Plug flow** describes a pattern in which alternate plugs of gas and liquid move along the upper part of the pipe. In **stratified flow,** the liquid flows along the bottom of the pipe and the gas flows over a smooth liquid/gas interface. Similar to stratified flow, **wavy flow** occurs at greater gas velocities and has waves moving in the flow direction. When wave crests are sufficiently high to bridge the pipe, they form frothy slugs which move at much greater than the average liquid velocity. **Slug flow** can cause severe and sometimes dangerous vibrations in equipment because of impact of the high-velocity slugs against bends or other fittings. Slugs may also flood gas/liquid separation equipment.

In **annular flow,** liquid flows as a thin film along the pipe wall and gas flows in the core. Some liquid is entrained as droplets in the gas

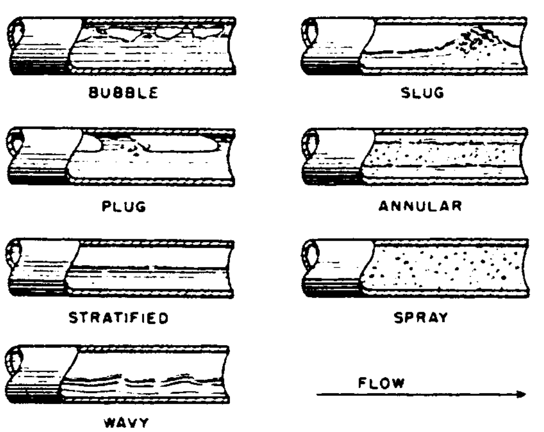

FIG. 6-24 Gas/liquid flow patterns in horizontal pipes. (*From Alves,* Chem. Eng. Progr., ***50,*** *449–456* [*1954*].)

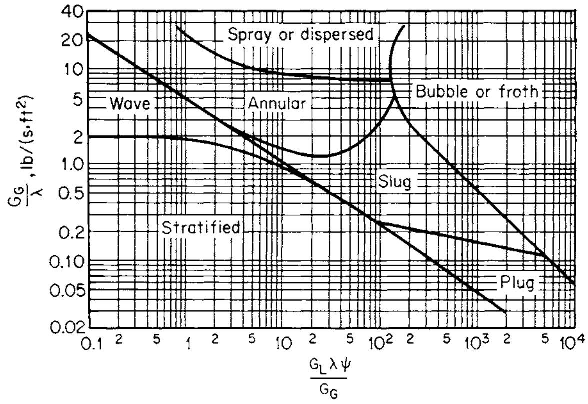

FIG. 6-25 Flow-pattern regions in cocurrent liquid/gas flow through horizontal pipes. To convert lbm/(ft$^2 \cdot$ s) to kg/(m$^2 \cdot$ s), multiply by 4.8824. (*From Baker,* Oil Gas J., ***53***[*12*], *185–190, 192, 195* [*1954*].)

core. At very high gas velocities, nearly all the liquid is entrained as small droplets. This pattern is called **spray, dispersed,** or **mist flow.**

Approximate prediction of flow pattern may be quickly done using **flow pattern maps,** an example of which is shown in Fig. 6-25 (Baker, *Oil Gas J.*, **53**[12], 185–190, 192–195 [1954]). The Baker chart remains widely used; however, for critical calculations the mechanistic model methods referenced previously are generally preferred for their greater accuracy, especially for large pipe diameters and fluids with physical properties different from air/water at atmospheric pressure. In the chart,

$$\lambda = (\rho'_G \rho'_L)^{1/2} \tag{6-129}$$

$$\psi = \frac{1}{\sigma'}\left[\frac{\mu'_L}{(\rho'_L)^2}\right]^{1/3} \tag{6-130}$$

G_L and G_G are the liquid and gas mass velocities, μ'_L is the ratio of liquid viscosity to water viscosity, ρ'_G is the ratio of gas density to air density, ρ'_L is the ratio of liquid density to water density, and σ' is the ratio of liquid surface tension to water surface tension. The reference properties are at 20°C (68°F) and atmospheric pressure, water density 1,000 kg/m^3 (62.4 lbm/ft^3), air density 1.20 kg/m^3 (0.075 lbm/ft^3), water viscosity 0.001 Pa · s (1.0 cP), and surface tension 0.073 N/m (0.0050 lbf/ft). The empirical parameters λ and ψ provide a crude accounting for physical properties. The Baker chart is dimensionally inconsistent since the dimensional quantity G_G/λ is plotted against a dimensionless one, $G_L\lambda\psi/G_G$, and so must be used with G_G in lbm/(ft$^2 \cdot$ s) units on the ordinate. To convert to kg/(m$^2 \cdot$ s), multiply by 4.8824.

Rapid approximate predictions of **pressure drop** for fully developed, incompressible horizontal gas/liquid flow may be made using the method of Lockhart and Martinelli (*Chem. Eng. Prog.*, **45,** 39–48 [1949]). First, the pressure drops that would be expected for each of the two phases as if flowing alone in single-phase flow are calculated. The Lockhart-Martinelli parameter X is defined in terms of the ratio of these pressure drops:

$$X = \left[\frac{(\Delta p/L)_L}{(\Delta p/L)_G}\right]^{1/2} \tag{6-131}$$

The two-phase pressure drop may then be estimated from either of the single-phase pressure drops, using

$$\left(\frac{\Delta p}{L}\right)_{TP} = Y_L\left(\frac{\Delta p}{L}\right)_L \tag{6-132}$$

or

$$\left(\frac{\Delta p}{L}\right)_{TP} = Y_G\left(\frac{\Delta p}{L}\right)_G \tag{6-133}$$

where Y_L and Y_G are read from Fig. 6-26 as functions of X. The curve labels refer to the flow regime (laminar or turbulent) found for each of

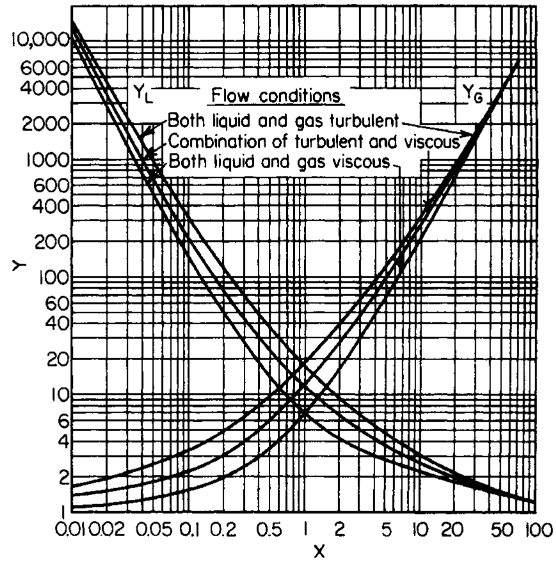

FIG. 6-26 Parameters for pressure drop in liquid/gas flow through horizontal pipes. (*Based on Lockhart and Martinelli,* Chem. Engr. Prog., ***45,*** *39* [*1949*].)

the phases flowing alone. The common turbulent-turbulent case is approximated well by

$$Y_L = 1 + \frac{20}{X} + \frac{1}{X^2} \tag{6-134}$$

Lockhart and Martinelli (ibid.) correlated pressure drop data from pipes 25 mm (1 in) in diameter or less within about ±50 percent. In general, the predictions are high for stratified, wavy, and slug flows and low for annular flow. The correlation can be applied to pipe diameters up to about 0.1 m (4 in) with about the same accuracy.

The **volume fraction,** sometimes called **holdup,** of each phase in two-phase flow is generally not equal to its volumetric flow rate fraction, because of velocity differences, or **slip,** between the phases. For each phase, denoted by subscript i, the relations among superficial velocity V_i, in situ velocity v_i, volume fraction R_i, total volumetric flow rate Q_i, and pipe area A are

$$Q_i = V_iA = v_iR_iA \tag{6-135}$$

$$v_i = \frac{V_i}{R_i} \tag{6-136}$$

The **slip velocity** between gas and liquid is $v_s = v_G - v_L$. For two-phase gas/liquid flow, $R_L + R_G = 1$. A very common mistake in practice is to assume that in situ phase volume fractions are equal to input volume fractions.

For fully developed incompressible horizontal gas/liquid flow, a quick estimate for R_L may be obtained from Fig. 6-27, as a function of the Lockhart-Martinelli parameter X defined by Eq. (6-131). Indications are that liquid volume fractions may be overpredicted for liquids more viscous than water (Alves, *Chem. Eng. Prog.*, **50,** 449–456 [1954]), and underpredicted for pipes larger than 25 mm diameter (Baker, *Oil Gas J.*, **53**[12], 185–190, 192–195 [1954]).

A method for predicting pressure drop and volume fraction for **non-Newtonian fluids** in annular flow has been proposed by Eisenberg and Weinberger (*AIChE J.*, **25,** 240–245 [1979]). Das, Biswas, and Matra (*Can. J. Chem. Eng.*, **70,** 431–437 [1993]) studied holdup in both horizontal and vertical gas/liquid flow with non-Newtonian liquids. Farooqi and Richardson (*Trans. Inst. Chem. Engrs.*, **60,** 292–305, 323–333 [1982]) developed correlations for holdup and pressure drop for gas/non-Newtonian liquid horizontal flow. They used a modified Lockhart-Martinelli parameter for non-Newtonian

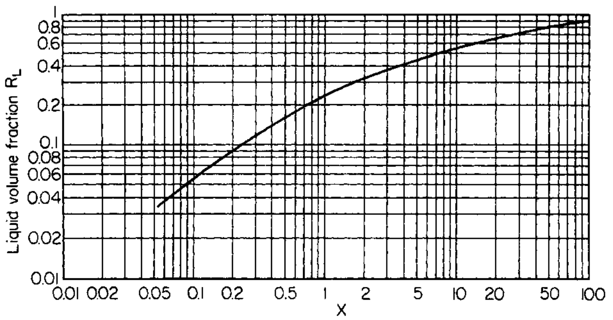

FIG. 6-27 Liquid volume fraction in liquid/gas flow through horizontal pipes. (*From Lockhart and Martinelli,* Eng. Prog., ***45,*** *39* [*1949*].)

liquid holdup. They found that two-phase pressure drop may actually be less than the single-phase liquid pressure drop with shear thinning liquids in laminar flow.

Pressure drop data for a 1-in **feed tee** with the liquid entering the run and gas entering the branch are given by Alves (*Chem. Eng. Progr.,* **50,** 449–456 [1954]). Pressure drop and division of two-phase **annular flow in a tee** are discussed by Fouda and Rhodes (*Trans. Inst. Chem. Eng.* [*London*], **52,** 354–360 [1974]). Flow through tees can result in unexpected flow splitting. Further reading on gas/liquid flow through tees may be found in Mudde, Groen, and van den Akker (*Int. J. Multiphase Flow,* **19,** 563–573 [1993]); Issa and Oliveira (*Computers and Fluids,* **23,** 347–372 [1993]) and Azzopardi and Smith (*Int. J. Multiphase Flow,* **18,** 861–875 [1992]).

Results by Chenoweth and Martin (*Pet. Refiner,* **34**[10], 151–155 [1955]) indicate that single-phase data for **fittings** and **valves** can be used in their correlation for two-phase pressure drop. Smith, Murdock, and Applebaum (*J. Eng. Power,* **99,** 343–347 [1977]) evaluated existing correlations for two-phase flow of steam/water and other gas/liquid mixtures through sharp-edged **orifices** meeting ASTM standards for flow measurement. The correlation of Murdock (*J. Basic Eng.,* **84,** 419–433 [1962]) may be used for these orifices. See also Collins and Gacesa (*J. Basic Eng.,* **93,** 11–21 [1971]), for measurements with steam and water beyond the limits of this correlation.

For pressure drop and holdup in **inclined pipe** with upward or downward flow, see Beggs and Brill (*J. Pet. Technol.,* **25,** 607–617 [1973]); the mechanistic model methods referenced above may also be applied to inclined pipes. Up to 10° from horizontal, upward pipe inclination has little effect on holdup (Gregory, *Can. J. Chem. Eng.,* **53,** 384–388 [1975]).

For fully developed incompressible **cocurrent upflow** of gases and liquids in **vertical pipes,** a variety of flow pattern terminologies and descriptions have appeared in the literature; some of these have been summarized and compared by Govier, Radford, and Dunn (*Can. J. Chem. Eng.,* **35,** 58–70 [1957]). One reasonable classification of patterns is illustrated in Fig. 6-28.

In **bubble flow,** gas is dispersed as bubbles throughout the liquid, but with some tendency to concentrate toward the center of the pipe. In **slug flow,** the gas forms large **Taylor bubbles** of diameter nearly equal to the pipe diameter. A thin film of liquid surrounds the Taylor bubble. Between the Taylor bubbles are liquid slugs containing some bubbles. **Froth** or **churn flow** is characterized by strong intermittency and intense mixing, with neither phase easily described as continuous or dispersed. There remains disagreement in the literature as to whether churn flow is a real fully developed flow pattern or is an indication of large entry length for developing slug flow (Zao and Dukler, *Int. J. Multiphase Flow,* **19,** 377–383 [1993]; Hewitt and Jayanti, *Int. J. Multiphase Flow,* **19,** 527–529 [1993]).

Ripple flow has an upward-moving wavy layer of liquid on the pipe wall; it may be thought of as a transition region to **annular, annular mist,** or **film flow,** in which gas flows in the core of the pipe while an annulus of liquid flows up the pipe wall. Some of the liquid is

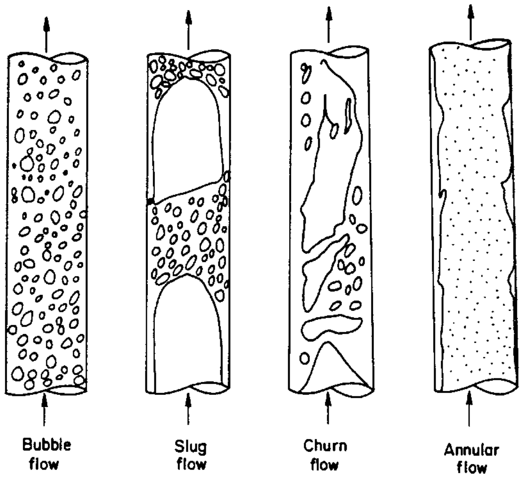

FIG. 6-28 Flow patterns in cocurrent upward vertical gas/liquid flow. (*From Taitel, Barnea, and Dukler,* AIChE J., ***26,*** *345–354* [*1980*]. *Reproduced by permission of the American Institute of Chemical Engineers © 1980 AIChE. All rights reserved.*)

entrained as droplets in the gas core. **Mist flow** occurs when all the liquid is carried as fine drops in the gas phase; this pattern occurs at high gas velocities, typically 20 to 30 m/s (66 to 98 ft/s).

The correlation by Govier, et al. (*Can. J. Chem. Eng.,* **35,** 58–70 [1957]), Fig. 6-29, may be used for quick estimate of flow pattern.

Slip, or relative velocity between phases, occurs for vertical flow as well as for horizontal. No completely satisfactory, flow regime–independent correlation for volume fraction or holdup exists for vertical flow. Two frequently used flow regime–independent methods are those by Hughmark and Pressburg (*AIChE J.,* **7,** 677 [1961]) and Hughmark (*Chem. Eng. Prog.,* **58**[4], 62 [April 1962]). **Pressure drop** in **upflow** may be calculated by the procedure described in Hughmark (*Ind. Eng. Chem. Fundam.,* **2,** 315–321 [1963]). The mechanistic, flow regime–based methods are advisable for critical applications.

For **upflow** in **helically coiled tubes,** the flow pattern, pressure drop, and holdup can be predicted by the correlations of Banerjee, Rhodes, and Scott (*Can. J. Chem. Eng.,* **47,** 445–453 [1969]) and

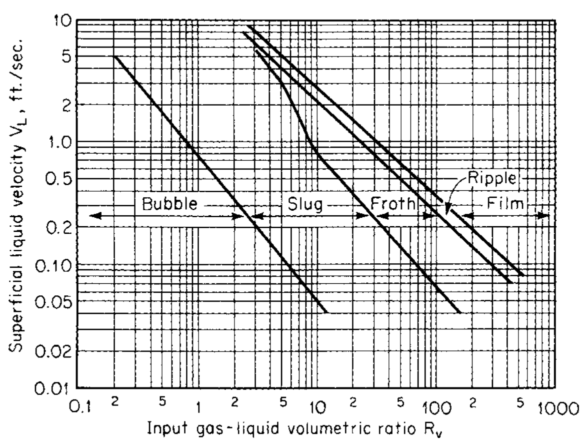

FIG. 6-29 Flow-pattern regions in cocurrent liquid/gas flow in upflow through vertical pipes. To convert ft/s to m/s, multiply by 0.3048. (*From Govier, Radford, and Dunn,* Can. J. Chem. Eng., **35,** *58–70* [*1957*].)

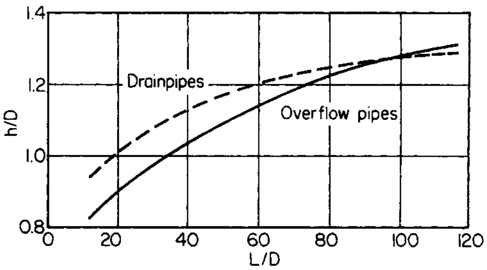

FIG. 6-30 Critical head for drain and overflow pipes. (*From Kalinske,* Univ. Iowa Stud. Eng., *Bull.* ***26*** *[1939–1940]*.)

Akagawa, Sakaguchi, and Ueda (*Bull JSME,* **14,** 564–571 [1971]). Correlations for flow patterns in **downflow** in vertical pipe are given by Oshinowo and Charles (*Can. J. Chem. Eng.,* **52,** 25–35 [1974]) and Barnea, Shoham, and Taitel (*Chem. Eng. Sci.,* **37,** 741–744 [1982]). Use of **drift flux theory** for void fraction modeling in downflow is presented by Clark and Flemmer (*Chem. Eng. Sci.,* **39,** 170–173 [1984]). **Downward inclined** two-phase flow data and modeling are given by Barnea, Shoham, and Taitel (*Chem. Eng. Sci.,* **37,** 735–740 [1982]). Data for **downflow** in **helically coiled tubes** are presented by Casper (*Chem. Ing. Tech.,* **42,** 349–354 [1970]).

The entrance to a **drain** is flush with a horizontal surface, while the entrance to an **overflow** pipe is above the horizontal surface. When such pipes do not run full, considerable amounts of gas can be drawn down by the liquid. The amount of gas entrained is a function of pipe diameter, pipe length, and liquid flow rate, as well as the drainpipe outlet boundary condition. Extensive data on air entrainment and liquid head above the entrance as a function of water flow rate for pipe diameters from 43.9 to 148.3 mm (1.7 to 5.8 in) and lengths from about 1.22 to 5.18 m (4.0 to 17.0 ft) are reported by Kalinske (*Univ. Iowa Stud. Eng.,* Bull. 26, pp. 26–40 [1939–1940]). For heads greater than the critical, the pipes will run full with no entrainment. The critical head h for flow of water in drains and overflow pipes is given in Fig. 6-30. Kalinske's results show little effect of the height of protrusion of overflow pipes when the protrusion height is greater than about one pipe diameter. For conservative design, McDuffie (*AIChE J.,* **23,** 37–40 [1977]) recommends the following relation for minimum liquid height to prevent entrainment.

$$\text{Fr} \le 1.6\left(\frac{h}{D}\right)^2 \tag{6-137}$$

where the Froude number is defined by

$$\text{Fr} \equiv \frac{V_L}{\sqrt{g(\rho_L - \rho_G)D/\rho_L}} \tag{6-138}$$

where g = acceleration due to gravity
V_L = liquid velocity in the drain pipe
ρ_L = liquid density
ρ_G = gas density
D = pipe inside diameter
h = liquid height

For additional information, see Simpson (*Chem. Eng.,* **75**[6], 192–214 [1968]). A critical Froude number of 0.31 to ensure vented flow is widely cited. Recent results (Thorpe, *3d Int. Conf. Multi-phase Flow,* The Hague, Netherlands, 18–20 May 1987, paper K2, and *4th Int. Conf. Multi-phase Flow,* Nice, France, 19–21 June 1989, paper K4) show hysteresis, with different critical Froude numbers for flooding and unflooding of drain pipes, and the influence of end effects. Wallis, Crowley, and Hagi (*Trans. ASME J. Fluids Eng.,* 405–413 [June 1977]) examine the conditions for horizontal discharge pipes to run full.

Flashing flow and **condensing flow** are two examples of multiphase flow with **phase change.** Flashing flow occurs when pressure drops below the bubble point pressure of a flowing liquid. A frequently used one-dimensional model for flashing flow through nozzles and pipes is the **homogeneous equilibrium model** which assumes that both phases move at the same in situ velocity, and maintain vapor/liquid equilibrium. It may be shown that a **critical flow** condition, analogous to sonic or critical flow during compressible gas flow, is given by the following expression for the mass flux G in terms of the derivative of pressure p with respect to mixture density ρ_m at constant entropy:

$$G_{\text{crit}} = \rho_m \sqrt{\left(\frac{\partial p}{\partial \rho_m}\right)_s} \tag{6-139}$$

The corresponding acoustic velocity $\sqrt{(\partial p/\partial \rho_m)_s}$ is normally much less than the acoustic velocity for gas flow. The mixture density is given in terms of the individual phase densities and the **quality** (mass flow fraction vapor) x by

$$\frac{1}{\rho_m} = \frac{x}{\rho_G} + \frac{1-x}{\rho_L} \tag{6-140}$$

Choked and unchoked flow situations arise in pipes and nozzles in the same fashion for homogeneous equilibrium flashing flow as for gas flow. For nozzle flow from stagnation pressure p_0 to exit pressure p_1, the mass flux is given by

$$G^2 = -2\rho_{m1}^2 \int_{p_0}^{p_1} \frac{dp}{\rho_m} \tag{6-141}$$

The integration is carried out over an isentropic flash path: flashes at constant entropy must be carried out to evaluate ρ_m as a function of p. Experience shows that isenthalpic flashes provide good approximations unless the liquid mass fraction is very small. Choking occurs when G obtained by Eq. (6-141) goes through a maximum at a value of p_1 greater than the external discharge pressure. Equation (6-139) will also be satisfied at that point. In such a case the pressure at the nozzle exit equals the choking pressure and flashing shocks occur outside the nozzle exit.

For homogeneous flow in a pipe of diameter D, the differential form of the Bernoulli equation (6-15) rearranges to

$$\frac{dp}{\rho_m} + g\,dz + \frac{G^2}{\rho_m}\,d\,\frac{1}{\rho_m} + 2f\,\frac{dx'}{D}\,\frac{G^2}{\rho_m^2} = 0 \tag{6-142}$$

where x' is distance along the pipe. Integration over a length L of pipe assuming constant friction factor f yields

$$G^2 = \frac{-\int_{p_1}^{p_2} \rho_m\,dp - g\int_{z_1}^{z_2} \rho_m^2\,dz}{\ln(\rho_{m1}/\rho_{m2}) + 2fL/D} \tag{6-143}$$

Frictional pipe flow is not isentropic. Strictly speaking, the flashes must be carried out at constant $h + V^2/2 + gz$, where h is the enthalpy per unit mass of the two-phase flashing mixture. The flash calculations are fully coupled with the integration of the Bernoulli equation; the velocity V must be known at every pressure p to evaluate ρ_m. Computational routines, employing the thermodynamic and material balance features of flowsheet simulators, are the most practical way to carry out such flashing flow calculations, particularly when multicompent systems are involved. Significant simplification arises when the mass fraction liquid is large, for then the effect of the $V^2/2$ term on the flash splits may be neglected. If elevation effects are also negligible, the flash computations are decoupled from the Bernoulli equation integration. For many horizontal flashing flow calculations, this is satisfactory and the flash computatations may be carried out first, to find ρ_m as a function of p from p_1 to p_2, which may then be substituted into Eq. (6-143).

With flashes carried out along the appropriate thermodynamic paths, the formalism of Eqs. (6-139) through (6-143) applies to all homogeneous equilibrium compressible flows, including, for example, flashing flow, ideal gas flow, and nonideal gas flow. Equation (6-118), for example, is a special case of Eq. (6-141) where the quality $x = 1$ and the vapor phase is a perfect gas.

Various **nonequilibrium** and **slip flow** models have been proposed as improvements on the homogeneous equilibrium flow model. See, for example, Henry and Fauske (*Trans. ASME J. Heat Transfer,* 179–187 [May 1971]). Nonequilibrium and slip effects both increase

computed mass flux for fixed pressure drop, compared to homogeneous equilibrium flow. For flow paths greater than about 100 mm, homogeneous equilibrium behavior appears to be the best assumption (Fischer, et al., *Emergency Relief System Design Using DIERS Technology,* AIChE, New York [1992]). For shorter flow paths, the best estimate may sometimes be given by linearly interpolating (as a function of length) between **frozen flow** (constant quality, no flashing) at 0 length and equilibrium flow at 100 mm.

In a series of papers by Leung and coworkers (*AIChE J.,* **32,** 1743–1746 [1986]; **33,** 524–527 [1987]; **34,** 688–691 [1988]; *J. Loss Prevention Proc. Ind.,* **2**[2], 78–86 [April 1989]; **3**[1], 27–32 [January 1990]; *Trans. ASME J. Heat Transfer,* **112,** 524–528, 528–530 [1990]; **113,** 269–272 [1991]) approximate techniques have been developed for homogeneous equilibrium calculations based on pseudo–equation of state methods for flashing mixtures.

Relatively less work has been done on **condensing flows.** Slip effects are more important for condensing than for flashing flows. Soliman, Schuster, and Berenson (*J. Heat Transfer,* **90,** 267–276 [1968]) give a model for condensing vapor in **horizontal pipe.** They assume the condensate flows as an annular ring. The Lockhart-Martinelli correlation is used for the frictional pressure drop. To this pressure drop is added an acceleration term based on homogeneous flow, equivalent to the $G^2d(1/\rho_m)$ term in Eq. (6-142). Pressure drop is computed by integration of the incremental pressure changes along the length of pipe.

For **condensing vapor** in **vertical downflow,** in which the liquid flows as a thin annular film, the frictional contribution to the pressure drop may be estimated based on the gas flow alone, using the friction factor plotted in Fig. 6-31, where Re_G is the Reynolds number for the gas flowing alone (Bergelin et al., *Proc. Heat Transfer Fluid Mech. Inst.,* ASME, June 22–24, 1949, pp. 19–28).

$$-\frac{dp}{dz} = \frac{2f'_G\rho_G V_G^2}{D} \tag{6-144}$$

To this should be added the $G_G^2 d(1/\rho_G)/dx$ term to account for velocity change effects.

Gases and Solids The flow of gases and solids in **horizontal** pipe is usually classified as either **dilute phase** or **dense phase** flow. Unfortunately, there is no clear dilineation between the two types of flow, and the *dense phase* description may take on more than one meaning, creating some confusion (Knowlton et al., *Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]). For dilute phase flow, achieved at low solids-to-gas weight ratios (loadings), and high gas velocities, the solids may be fully suspended and fairly uniformly dispersed over the pipe cross section (homogeneous flow), particularly for low-density or small particle size solids. At lower gas velocities, the solids may bounce along the bottom of the pipe. With higher loadings and lower gas velocities, the particles may settle to the bottom of the pipe, forming dunes, with the particles moving from dune to dune. In dense phase conveying, solids tend to concentrate in the lower portion of the pipe at high gas velocity. As gas velocity decreases, the solids may first form dense moving strands, followed by slugs. Discrete plugs of solids may be created intentionally by timed injection of solids, or the plugs may form spontaneously. Eventually the pipe may become blocked. For more information on flow patterns, see Coulson and Richardson (*Chemical Engineering,* vol. 2, 2d ed., Pergamon, New York, 1968, p. 583); Korn (*Chem. Eng.,* **57**[3], 108–111 [1950]); Patterson (*J. Eng. Power,* **81,** 43–54 [1959]); Wen and Simons (*AIChE J.,* **5,** 263–267 [1959]); and Knowlton et al. (*Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]).

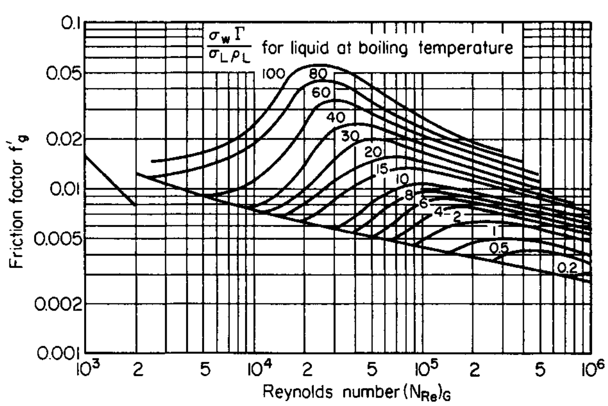

FIG. 6-31 Friction factors for condensing liquid/gas flow downward in vertical pipe. In this correlation $\Gamma/\rho L$ is in ft²/h. To convert ft²/h to m²/s, multiply by 0.00155. (*From Bergelin et al.,* Proc. Heat Transfer Fluid Mech. Inst., *ASME, 1949, p. 19.*)

For the **minimum velocity** required to prevent formation of dunes or settled beds in **horizontal flow,** some data are given by Zenz (*Ind. Eng. Chem. Fundam.,* **3,** 65–75 [1964]), who presented a correlation for the minimum velocity required to keep particles from depositing on the bottom of the pipe. This rather tedious estimation procedure may also be found in Govier and Aziz, who provide additional references and discussion on transition velocities. In practice, the actual conveying velocities used in systems with loadings less than 10 are generally over 15 m/s, (49 ft/s) while for high loadings (>20) they are generally less than 7.5 m/s (24.6 ft/s) and are roughly twice the actual solids velocity (Wen and Simons, *AIChE J.,* **5,** 263–267 [1959]).

Total **pressure drop** for **horizontal gas/solid** flow includes acceleration effects at the entrance to the pipe and frictional effects beyond the entrance region. A great number of correlations for pressure gradient are available, none of which is applicable to all flow regimes. Govier and Aziz review many of these and provide recommendations on when to use them.

For **upflow** of gases and solids in **vertical pipes,** the **minimum conveying velocity** for low loadings may be estimated as twice the terminal settling velocity of the largest particles. Equations for terminal settling velocity are found in the "Particle Dynamics" subsection, following. **Choking** occurs as the velocity is dropped below the minimum conveying velocity and the solids are no longer transported, collapsing into solid plugs (Knowlton, et al., *Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]). See Smith (*Chem. Eng. Sci.,* **33,** 745–749 [1978]) for an equation to predict the onset of choking.

Total **pressure drop** for vertical upflow of gases and solids includes acceleration and frictional affects also found in horizontal flow, plus potential energy or hydrostatic effects. Govier and Aziz review many of the pressure drop calculation methods and provide recommendations for their use. See also Yang (*AIChE J.,* **24,** 548–552 [1978]).

Drag reduction has been reported for low loadings of small diameter particles (<60 μm diameter), ascribed to damping of turbulence near the wall (Rossettia and Pfeffer, *AIChE J.,* **18,** 31–39 [1972]).

For **dense phase** transport in **vertical pipes** of small diameter, see Sandy, Daubert, and Jones (*Chem. Eng. Prog.,* **66,** *Symp. Ser.,* 105, 133–142 [1970]).

The **flow of bulk solids through restrictions and bins** is discussed in symposium articles (*J. Eng. Ind.,* **91**[2] [1969]) and by Stepanoff (*Gravity Flow of Bulk Solids and Transportation of Solids in Suspension,* Wiley, New York, 1969). Some problems encountered in discharge from bins include (Knowlton et al., *Chem. Eng. Progr.,* **90**[4], 44–54 [April 1994]) flow stoppage due to **ratholing** or **arching, segregation** of fine and coarse particles, **flooding** upon collapse of ratholes, and poor **residence time distribution** when **funnel flow** occurs.

Solid and Liquids Slurry flow may be divided roughly into two categories based on settling behavior (see Etchells in Shamlou, *Processing of Solid-Liquid Suspensions,* Chap. 12, Butterworth-Heinemann, Oxford, 1993). **Nonsettling** slurries are made up of very fine, highly concentrated, or neutrally buoyant particles. These slurries are normally treated as pseudohomogeneous fluids. They may be quite viscous and are frequently non-Newtonian. Slurries of particles that tend to settle out rapidly are called **settling slurries** or **fast-settling slurries.** While in some cases positively buoyant solids are encountered, the present discussion will focus on solids which are more dense than the liquid.

For **horizontal flow** of **fast-settling slurries,** the following rough description may be made (Govier and Aziz). Ultrafine particles, 10 μm

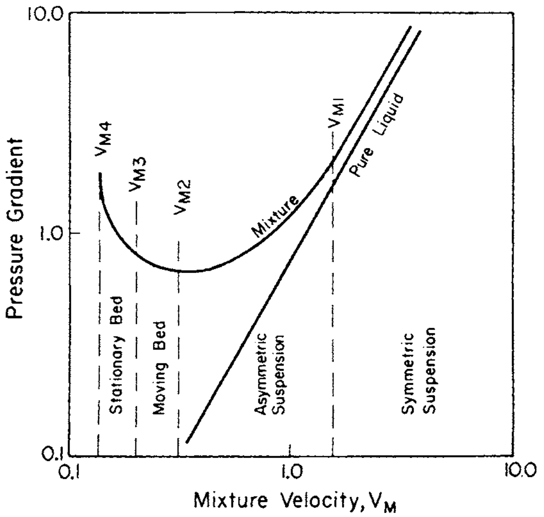

FIG. 6-32 Flow pattern regimes and pressure gradients in horizontal slurry flow. (*From Govier and Aziz,* The Flow of Complex Mixtures in Pipes, *Van Nostrand Reinhold, New York, 1972.*)

or smaller, are generally fully syspended and the particle distributions are not influenced by gravity. Fine particles 10 to 100 μm (3.3×10^{-5} to 33×10^{-5} ft) are usually fully suspended, but gravity causes concentration gradients. Medium-size particles, 100 to 1000 μm, may be fully suspended at high velocity, but often form a moving deposit on the bottom of the pipe. Coarse particles, 1,000 to 10,000 μm (0.0033 to 0.033 ft), are seldom fully suspended and are usually conveyed as a moving deposit. Ultracoarse particles larger than 10,000 μm (0.033 ft) are not suspended at normal velocities unless they are unusually light.

Figure 6-32, taken from Govier and Aziz, schematically indicates four flow pattern regions superimposed on a plot of pressure gradient vs. mixture velocity $V_M = V_L + V_S = (Q_L + Q_S)/A$ where V_L and V_S are the superficial liquid and solid velocities, Q_L and Q_S are liquid and solid volumetric flow rates, and A is the pipe cross-sectional area. V_{M4} is the transition velocity above which a bed exists in the bottom of the pipe, part of which is stationary and part of which moves by **saltation,** with the upper particles tumbling and bouncing over one another, often with formation of dunes. With a broad particle-size distribution, the finer particles may be fully suspended. Near V_{M4}, the pressure gradient rapidly increases as V_M decreases. Above V_{M3}, the entire bed moves. Above V_{M2}, the solids are fully suspended; that is, there is no deposit, moving or stationary, on the bottom of the pipe. However, the concentration distribution of solids is asymmetric. This flow pattern is the most frequently used for fast-settling slurry transport. Typical mixture velocities are in the range of 1 to 3 m/s (3.3 to 9.8 ft/s). The minimum in the pressure gradient is found to be near V_{M2}. Above V_{M1}, the particles are symmetrically distributed, and the pressure gradient curve is nearly parallel to that for the liquid by itself.

The most important transition velocity, often regarded as the minimum transport or conveying velocity for settling slurries, is V_{M2}. The Durand equation (Durand, Minnesota Int. Hydraulics Conf., *Proc.*, 89, Int. Assoc. for Hydraulic Research [1953]; Durand and Condolios, *Proc. Colloq. On the Hyd. Transport of Solids in Pipes, Nat. Coal Board* [*UK*], Paper IV, 39–35 [1952]) gives the minimum transport velocity as

$$V_{M2} = F_L[2gD(s-1)]^{0.5} \tag{6-145}$$

where g = acceleration of gravity
D = pipe diameter
$s = \rho_S/\rho_L$ = ratio of solid to liquid density
F_L = a factor influenced by particle size and concentration

Probably F_L is a function of particle Reynolds number and concentration, but Fig. 6-33 gives Durand's empirical correlation for F_L as a function of particle diameter and the input, feed volume fraction

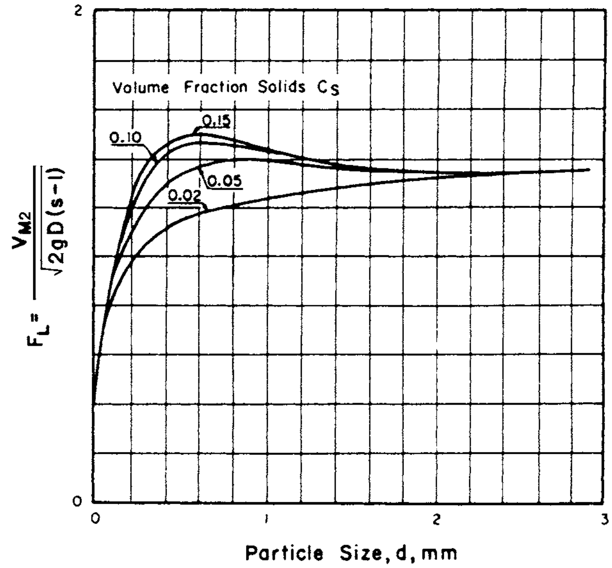

FIG. 6-33 Durand factor for minimum suspension velocity. (*From Govier and Aziz,* The Flow of Complex Mixtures in Pipes, *Van Nostrand Reinhold, New York, 1972.*)

solids, $C_S = Q_S/(Q_S + Q_L)$. The form of Eq. (6-145) may be derived from turbulence theory, as shown by Davies (*Chem. Eng. Sci.,* **42,** 1667–1670 [1987]).

No single correlation for **pressure drop** in horizontal solid/liquid flow has been found satisfactory for all particle sizes, densities, concentrations, and pipe sizes. However, with reference to Fig. 6-32, the following simplifications may be considered. The minimum pressure gradient occurs near V_{M2} and for conservative purposes it is generally desirable to exceed V_{M2}. When V_{M2} is exceeded, a rough guide for pressure drop is 25 percent greater than that calculated assuming that the slurry behaves as a psuedohomogeneous fluid with the density of the mixture and the viscosity of the liquid. Above the transition velocity to symmetric suspension, V_{M1}, the pressure drop closely approaches the pseudohomogeneous pressure drop. The following correlation by Spells (*Trans. Inst. Chem. Eng.* [*London*], **33,** 79–84 [1955]) may be used for V_{M1}.

$$V_{M1}^2 = 0.075 \left(\frac{DV_{M1}\rho_M}{\mu}\right)^{0.775} gD_S(s-1) \tag{6-146}$$

where D = pipe diameter
D_S = particle diameter (such that 85 percent by weight of particles are smaller than D_S)
ρ_M = the slurry mixture density
μ = liquid viscosity
$s = \rho_S/\rho_L$ = ratio of solid to liquid density

Between V_{M2} and V_{M1} the concentration of solids gradually becomes more uniform in the vertical direction. This transition has been modeled by several authors as a concentration gradient where turbulent diffusion balances gravitational settling. See, for example, Karabelas (*AIChE J.*, **23,** 426–434 [1977]).

Published correlations for pressure drop are frequently very complicated and tedious to use, may not offer significant accuracy advantages over the simple guide given here, and many of them are applicable only for velocities above V_{M2}. One which does include the effect of sliding beds is due to Gaessler (Doctoral Dissertation, Technische Hochshule, Karlsruhe, Germany [1967]; reproduced by Govier and Aziz, pp. 668–669). Turian and Yuan (*AIChE J.*, **23,** 232–243 [1977]; see also Turian and Oroskar, *AIChE J.*, **24,** 1144 [1978]) segregated a large body of data into four flow regime groups

and developed empirical correlations for predicting pressure drop in each flow regime.

Pressure drop data for the flow of **paper stock** in pipes are given in the data section of *Standards of the Hydraulic Institute* (Hydraulic Institute, 1965). The flow behavior of fiber suspensions is discussed by Bobkowicz and Gauvin (*Chem. Eng. Sci.,* **22,** 229–241 [1967]), Bugliarello and Daily (*TAPPI,* **44,** 881–893 [1961]), and Daily and Bugliarello (*TAPPI,* **44,** 497–512 [1961]).

In **vertical flow** of fast-settling slurries, the in situ concentration of solids with density greater than the liquid will exceed the feed concentration $C = Q_S/(Q_S + Q_L)$ for upflow and will be smaller than C for downflow. This results from slip between the phases. The **slip velocity,** the difference between the in situ average velocities of the two phases, is roughly equal to the terminal settling velocity of the solids in the liquid. Specification of the slip velocity for a pipe of a given diameter, along with the phase flow rates, allows calculation of in situ volume fractions, average velocities, and holdup ratios by simple material balances. Slip velocity may be affected by particle concentration and by turbulence conditions in the liquid. **Drift-flux theory,** a framework incorporating certain functional forms for empirical expressions for slip velocity, is described by Wallis (*One-Dimensional Two-Phase Flow,* McGraw-Hill, New York, 1969). **Minimum transport velocity** for upflow for design purposes is usually taken as twice the particle settling velocity. **Pressure drop** in vertical pipe flow includes the effects of kinetic and potential energy (elevation) changes and friction. Rose and Duckworth (*The Engineer,* **227**[5,903], 392 [1969]; **227**[5,904], 430 [1969]; **227**[5,905], 478 [1969]; see also Govier and Aziz, pp. 487–493) have developed a calculation procedure including all these effects, which may be applied not only to vertical solid/liquid flow, but also to gas/solid flow and to horizontal flow.

For fast-settling slurries, ensuring conveyance is usually the key design issue while pressure drop is somewhat less important. For **nonsettling slurries** conveyance is not an issue, because the particles do not separate from the liquid. Here, viscous and rheological behavior, which control pressure drop, take on critical importance.

Fine particles, often at high concentration, form nonsettling slurries for which useful design equations can be developed by treating them as homogeneous fluids. These fluids are usually very viscous and often non-Newtonian. Shear-thinning and Bingham plastic behavior are common; dilatancy is sometimes observed. Rheology of such fluids must in general be empirically determined, although theoretical results are available for some very limited circumstances. Further discussion of both fast-settling and nonsettling slurries may be found in Shook (in Shamlou, *Processing of Solid-Liquid Suspensions,* Chap. 11, Butterworth-Heinemann, Oxford, 1993).

FLUID DISTRIBUTION

Uniform fluid distribution is essential for efficient operation of chemical-processing equipment such as contactors, reactors, mixers, burners, heat exchangers, extrusion dies, and textile-spinning chimneys. To obtain optimum distribution, proper consideration must be given to flow behavior in the distributor, flow conditions upstream and downstream of the distributor, and the distribution requirements of the equipment. Even though the principles of fluid distribution have been well developed for more than three decades, they are frequently overlooked by equipment designers, and a significant fraction of process equipment needlessly suffers from maldistribution. In this subsection, guides for the design of various types of fluid distributors, taking into account only the flow behavior within the distributor, are given.

Perforated-Pipe Distributors The simple perforated pipe or sparger (Fig. 6-34) is a common type of distributor. As shown, the flow distribution is uniform; this is the case in which pressure recovery due to kinetic energy or momentum changes, frictional pressure drop along the length of the pipe, and pressure drop across the outlet holes have been properly considered. In typical turbulent flow applications, inertial effects associated with velocity changes may dominate frictional losses in determining the pressure distribution along the pipe, unless the length between orifices is large. Application of the momentum or mechanical energy equations in such a case shows that the pressure inside the pipe increases with distance from the entrance of the pipe. If the outlet holes are uniform in size and spacing, the discharge flow will be biased toward the closed end. Disturbances upstream of the distributor, such as pipe bends, may increase or decrease the flow to the holes at the beginning of the distributor. When frictional pressure drop dominates the inertial pressure recovery, the distribution is biased toward the feed end of the distributor**.**

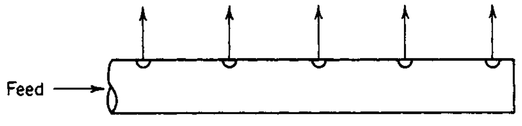

FIG. 6-34 Perforated-pipe distributor.

For turbulent flow, with roughly uniform distribution, assuming a constant friction factor, the combined effect of friction and inertial (momentum) pressure recovery is given by

$$\Delta p = \left(\frac{4fL}{3D} - 2K\right)\frac{\rho V_i^2}{2} \qquad \text{(discharge manifolds)} \qquad (6\text{-}147)$$

where Δp = net pressure drop over the length of the distributor
L = pipe length
D = pipe diameter
f = Fanning friction factor
V_i = distributor inlet velocity

The factor K would be 1 in the case of full momentum recovery, or 0.5 in the case of negligible viscous losses in the portion of flow which remains in the pipe after the flow divides at a takeoff point (Denn, pp. 126–127). Experimental data (Van der Hegge Zijnen, *Appl. Sci. Res.,* **A3,** 144–162 [1951–1953]; and Bailey, *J. Mech. Eng. Sci.,* **17,** 338–347 [1975]), while scattered, show that K is probably close to 0.5 for discharge manifolds. For inertially dominated flows, Δp will be negative. For **return manifolds** the recovery factor K is close to 1.0, and the pressure drop between the first hole and the exit is given by

$$\Delta p = \left(\frac{4fL}{3D} + 2K\right)\frac{\rho V_e^2}{2} \qquad \text{(return manifolds)} \qquad (6\text{-}148)$$

where V_e is the pipe exit velocity.

One means to obtain a desired uniform distribution is to make the average pressure drop across the holes Δp_o large compared to the pressure variation over the length of pipe Δp. Then, the relative variation in pressure drop across the various holes will be small, and so will be the variation in flow. When the area of an individual hole is small compared to the cross-sectional area of the pipe, hole pressure drop may be expressed in terms of the discharge coefficient C_o and the velocity across the hole V_o as

$$\Delta p_o = \frac{1}{C_o^2}\,\frac{\rho V_o^2}{2} \qquad (6\text{-}149)$$

Provided C_o is the same for all the holes, the *percent maldistribution,* defined as the percentage variation in flow between the first and last holes, may be estimated reasonably well for small maldistribution by (Senecal, *Ind. Eng. Chem.,* **49,** 993–997 [1957])

$$\text{Percent maldistribution} = 100\left(1 - \sqrt{\frac{\Delta p_o - |\Delta p|}{\Delta p_o}}\right) \qquad (6\text{-}150)$$

This equation shows that for 5 percent maldistribution, the pressure drop across the holes should be about 10 times the pressure drop over the length of the pipe. For discharge manifolds with $K = 0.5$ in Eq. (6-147), and with $4fL/3D << 1$, the pressure drop across the holes should be 10 times the inlet velocity head, $\rho V_i^2/2$ for 5 percent maldistribution. This leads to a simple design equation.

Discharge manifolds, $4fL/3D << 1$, 5% maldistribution:

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10}C_o \qquad (6\text{-}151)$$

Here A_p = pipe cross-sectional area and A_o is the *total* hole area of the distributor. Use of large hole velocity to pipe velocity ratios promotes perpendicular discharge streams. In practice, there are many cases where the $4fL/3D$ term will be less than unity but not close to zero. In such cases, Eq. (6-151) will be conservative, while Eqs. (6-147), (6-149), and (6-150) will give more accurate design calculations. In cases where $4fL/(3D) > 2$, friction effects are large enough to render Eq. (6-151) nonconservative. When significant variations in f along the length of the distributor occur, calculations should be made by dividing the distributor into small enough sections that constant f may be assumed over each section.

For return manifolds with $K = 1.0$ and $4fL/(3D) << 1$, 5 percent maldistribution is achieved when hole pressure drop is 20 times the pipe exit velocity head.

Return manifolds, $4fL/3D << 1$, 5% maldistribution:

$$\frac{V_o}{V_e} = \frac{A_p}{A_o} = \sqrt{20}C_o \tag{6-152}$$

When $4fL/3D$ is not negligible, Eq. (6-152) is not conservative and Eqs. (6-148), (6-149), and (6-150) should be used.

One common misconception is that good distribution is always provided by high pressure drop, so that increasing flow rate improves distribution by increasing pressure drop. Conversely, it is mistakenly believed that turndown of flow through a perforated pipe designed using Eqs. (6-151) and (6-152) will cause maldistribution. However, when the distribution is nearly uniform, decreasing the flow rate decreases Δp and Δp_o in the same proportion, and Eqs. (6-151) and (6-152) are still satisfied, preserving good distribution independent of flow rate, as long as friction losses remain small compared to inertial (velocity head change) effects. Conversely, increasing the flow rate through a distributor with severe maldistribution will not generally produce good distribution.

Often, the pressure drop required for design flow rate is unacceptably large for a distributor pipe designed for uniform velocity through uniformly sized and spaced orifices. Several measures may be taken in such situations. These include the following:

1. Taper the diameter of the distributor pipe so that the pipe velocity and velocity head remain constant along the pipe, thus substantially reducing pressure variation in the pipe.
2. Vary the hole size and/or the spacing between holes to compensate for the pressure variation along the pipe. This method may be sensitive to flow rate and a distributor optimized for one flow rate may suffer increased maldistribution as flow rate deviates from design rate.
3. Feed or withdraw from both ends, reducing the pipe flow velocity head and required hole pressure drop by a factor of 4.

The orifice discharge coefficient C_o is usually taken to be about 0.62. However, C_o is dependent on the ratio of hole diameter to pipe diameter, pipe wall thickness to hole diameter ratio, and pipe velocity to hole velocity ratio. As long as all these are small, the coefficient 0.62 is generally adequate.

Example 9: Pipe Distributor A 3-in schedule 40 (inside diameter 7.793 cm) pipe is to be used as a distributor for a flow of 0.010 m^3/s of water ($\rho = 1{,}000$ kg/m^3, $\mu = 0.001$ Pa · s). The pipe is 0.7 m long and is to have 10 holes of uniform diameter and spacing along the length of the pipe. The distributor pipe is submerged. Calculate the required hole size to limit maldistribution to 5 percent, and estimate the pressure drop across the distributor.

The inlet velocity computed from $V_i = Q/A = 4Q/(\pi D^2)$ is 2.10 m/s, and the inlet Reynolds number is

$$\text{Re} = \frac{DV_i\rho}{\mu} = \frac{0.07793 \times 2.10 \times 1{,}000}{0.001} = 1.64 \times 10^5$$

For commercial pipe with roughness $\epsilon = 0.046$ mm, the friction factor is about 0.0043. Approaching the last hole, the flow rate, velocity, and Reynolds number are about one-tenth their inlet values. At Re = 16,400 the friction factor f is about 0.0070. Using an average value of $f = 0.0057$ over the length of the pipe, $4fL/3D$ is 0.068 and may reasonably be neglected so that Eq. (6-151) may be used. With $C_o = 0.62$,

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10}C_o = \sqrt{10} \times 0.62 = 1.96$$

With pipe cross-sectional area A_p = 0.00477 m^2, the total hole area is 0.00477/1.96 = 0.00243 m^2. The area and diameter of each hole are then 0.00243/10 = 0.000243 m^2 and 1.76 cm. With $V_o/V_i = 1.96$, the hole velocity is 1.96 × 2.10 = 4.12 m/s and the pressure drop across the holes is obtained from Eq. (6-149).

$$\Delta p_o = \frac{1}{C_o^2}\frac{\rho V_o^2}{2} = \frac{1}{0.62^2} \times \frac{1{,}000(4.12)^2}{2} = 22{,}100 \text{ Pa}$$

Since the hole pressure drop is 10 times the pressure variation in the pipe, the total pressure drop from the inlet of the distributor may be taken as approximately 22,100 Pa.

Further detailed information on pipe distributors may be found in Senecal (*Ind. Eng. Chem.,* **49,** 993–997 [1957]). Much of the information on tapered manifold design has appeared in the pulp and paper literature (Spengos and Kaiser, *TAPPI,* **46**[3], 195–200 [1963]; Madeley, *Paper Technology,* **9**[1], 35–39 [1968]; Mardon, et al., *TAPPI,* **46**[3], 172–187 [1963]; Mardon, et al., *Pulp and Paper Magazine of Canada,* **72**[11], 76–81 [November 1971]; Trufitt, *TAPPI,* **58**[11], 144–145 [1975]).

Slot Distributors These are generally used in sheeting dies for extrusion of films and coatings and in air knives for control of thickness of a material applied to a moving sheet. A simple slotted pipe for turbulent flow conditions may give severe maldistribution because of nonuniform discharge velocity, but also because this type of design does not readily give perpendicular discharge (Koestel and Tuve, *Heat. Piping Air Cond.,* **20**[1], 153–157 [1948]; Senecal, *Ind. Eng. Chem.,* **49,** 993–997 [1957]; Koestel and Young, *Heat. Piping Air Cond.,* **23**[7], 111–115 [1951]). For slots in tapered ducts where the duct cross-sectional area decreases linearly to zero at the far end, the discharge angle will be constant along the length of the duct (Koestel and Young, ibid.). One way to ensure an almost perpendicular discharge is to have the ratio of the area of the slot to the cross-sectional area of the pipe equal to or less than 0.1. As in the case of perforated-pipe distributors, pressure variation within the slot manifold and pressure drop across the slot must be carefully considered.

In practice, the following methods may be used to keep the diameter of the pipe to a minimum consistent with good performance (Senecal, *Ind. Eng. Chem.,* **49,** 993–997 [1957]):

1. Feed from both ends.
2. Modify the cross-sectional design (Fig. 6-35); the slot is thus farther away from the influence of feed-stream velocity.
3. Increase pressure drop across the slot; this can be accomplished by lengthening the lips (Fig. 6-35).
4. Use screens (Fig. 6-35) to increase overall pressure drop across the slot.

Design considerations for air knives are discussed by Senecal (ibid.). Design procedures for extrusion dies when the flow is laminar, as with highly viscous fluids, are presented by Bernhardt (*Processing of Thermoplastic Materials,* Rheinhold, New York, 1959, pp. 248–281).

Turning Vanes In applications such as ventilation, the discharge profile from slots can be improved by turning vanes. The tapered duct is the most amenable for turning vanes because the discharge angle remains constant. One way of installing the vanes is shown in Fig. 6-36. The vanes should have a depth twice the spacing (*Heating, Ventilating, Air Conditioning Guide,* vol. 38, American Society of Heating, Refrigerating and Air-Conditioning Engineers, 1960, pp. 282–283) and a curvature at the upstream end of the vanes of a circular arc which is tangent to the discharge angle θ of a slot without vanes and perpendicular at the downstream or discharge end of the vanes (Koestel and Young, *Heat. Piping Air Cond.,* **23**[7], 111–115 [1951]). Angle θ can be estimated from

$$\cot\theta = \frac{C_d A_s}{A_d} \tag{6-153}$$

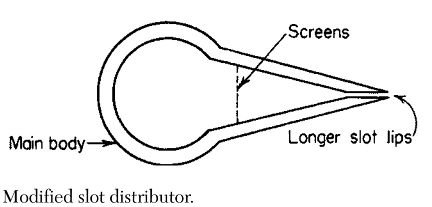

FIG. 6-35 Modified slot distributor.

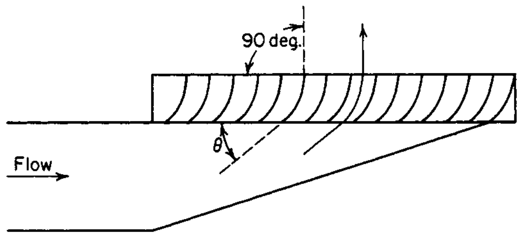

FIG. 6-36 Turning vanes in a slot distributor.

where A_s = slot area
A_d = duct cross-sectional area at upstream end
C_d = discharge coefficient of slot

Vanes may be used to improve velocity distribution and reduce frictional loss in bends, when the ratio of bend turning radius to pipe diameter is less than 1.0. For a miter bend with low-velocity flows, simple circular arcs (Fig. 6-37) can be used, and with high-velocity flows, vanes of special airfoil shapes are required. For additional details and references, see Ower and Pankhurst (*The Measurement of Air Flow,* Pergamon, New York, 1977, p. 102); Pankhurst and Holder (*Wind-Tunnel Technique,* Pitman, London, 1952, pp. 92–93); Rouse (*Engineering Hydraulics,* Wiley, New York, 1950, pp. 399–401); and Jorgensen (*Fan Engineering,* 7th ed., Buffalo Forge Co., Buffalo, 1970, pp. 111, 117, 118).

Perforated Plates and Screens A nonuniform velocity profile in turbulent flow through channels or process equipment can be smoothed out to any desired degree by adding sufficient uniform resistance, such as perforated plates or screens across the flow channel, as shown in Fig. 6-38. Stoker (*Ind. Eng. Chem.,* **38,** 622–624 [1946]) provides the following equation for the effect of a uniform resistance on velocity profile:

$$\frac{V_{2,\max}}{V} = \sqrt{\frac{(V_{1,\max}/V)^2 + \alpha_2 - \alpha_1 + \alpha_2 K}{1 + K}} \qquad (6\text{-}154)$$

Here, V is the area average velocity, K is the number of velocity heads of pressure drop provided by the uniform resistance, $\Delta p = K\rho V^2/2$, and α is the velocity profile factor used in the mechanical energy balance, Eq. (6-13). It is the ratio of the area average of the cube of the velocity, to the cube of the area average velocity V. The shape of the exit velocity profile appears twice in Eq. (6-154), in $V_{2,\max}/V$ and α_2. Typically, K is on the order of 10, and the desired exit velocity profile

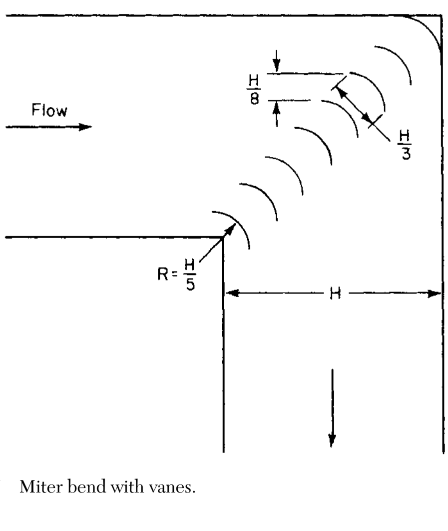

FIG. 6-37 Miter bend with vanes.

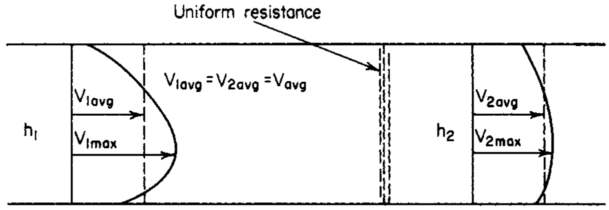

FIG. 6-38 Smoothing out a nonuniform profile in a channel.

is fairly uniform so that $\alpha_2 \sim 1.0$ may be appropriate. Downstream of the resistance, the velocity profile will gradually reestablish the fully developed profile characteristic of the Reynolds number and channel shape. The screen or perforated plate open area required to produce the resistance K may be computed from Eqs. (6-107) or (6-111).

Screens and other flow restrictions may also be used to suppress stream swirl and turbulence (Loehrke and Nagib, *J. Fluids Eng.,* **98,** 342–353 [1976]). Contraction of the channel, as in a venturi, provides further reduction in turbulence level and flow nonuniformity.

Beds of Solids A suitable depth of solids can be used as a fluid distributor. As for other types of distribution devices, a pressure drop of 10 velocity heads is typically used, here based on the superficial velocity through the bed. There are several substantial disadvantages to use of particle beds for flow distribution. Heterogeneity of the bed may actually worsen rather than improve distribution. In general, uniform flow may be found only downstream of the point in the bed where sufficient pressure drop has occurred to produce uniform flow. Therefore, inefficiency results when the bed also serves reaction or mass transfer functions, as in catalysts, adsorbents, or tower packings for gas/liquid contacting, since portions of the bed are bypassed. In the case of trickle flow of liquid downward through column packings, inlet distribution is critical since the bed itself is relatively ineffective in distributing the liquid. Maldistribution of flow through packed beds also arises when the ratio of bed diameter to particle size is less than 10 to 30.

Other Flow Straightening Devices Other devices designed to produce uniform velocity or reduce swirl, sometimes with reduced pressure drop, are available. These include both commercial devices of proprietary design and devices discussed in the literature. For pipeline flows, see the references under flow inverters and static mixing elements previously discussed in the "Incompressible Flow in Pipes and Channels" subsection. For large area changes, as at the entrance to a vessel, it is sometimes necessary to diffuse the momentum of the inlet jet discharging from the feed pipe in order to produce a more uniform velocity profile within the vessel. Methods for this application exist, but remain largely in the domain of proprietary, commercial design.

FLUID MIXING

Mixing of fluids is a discipline of fluid mechanics. Fluid motion is used to accelerate the otherwise slow processes of diffusion and conduction to bring about uniformity of concentration and temperature, blend materials, facilitate chemical reactions, bring about intimate contact of multiple phases, and so on. As the subject is too broad to cover fully, only a brief introduction and some references for further information are given here.

Several texts are available. These include Paul, Atiemo-Obeng, and Kresta (*Handbook of Industrial Mixing,* Wiley-Interscience, Hoboken N.J., 2004); Harnby, Edwards, and Nienow (*Mixing in the Process Industries,* 2d ed., Butterworths, London, 1992); Oldshue (*Fluid Mixing Technology,* McGraw-Hill, New York, 1983); Tatterson (*Fluid Mixing and Gas Dispersion in Agitated Tanks,* McGraw-Hill, New York, 1991); Uhl and Gray (*Mixing,* vols. I–III, Academic, New York, 1966, 1967, 1986); and Nagata (*Mixing: Principles and Applications,* Wiley, New York, 1975). A good overview of stirred tank agitation is given in the series of articles from *Chemical Engineering* (110–114, Dec. 8, 1975; 139–145, Jan. 5, 1976; 93–100, Feb. 2, 1976; 102–110,

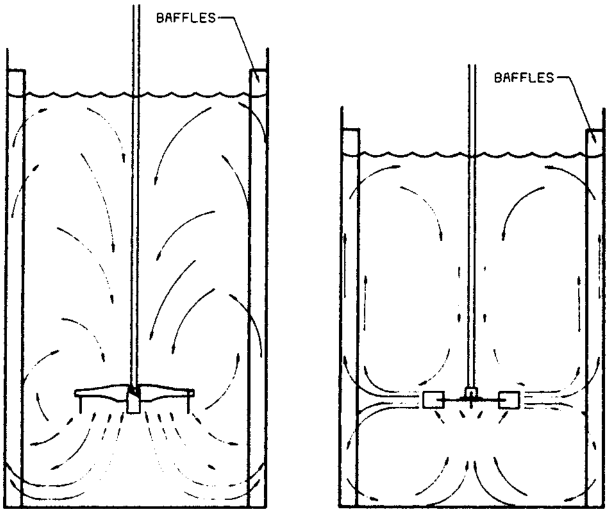

FIG. 6-39 Typical stirred tank configurations, showing time-averaged flow patterns for axial flow and radial flow impellers. (*From Oldshue,* Fluid Mixing Technology, *McGraw-Hill, New York, 1983.*)

Apr. 26, 1976; 144–150, May 24, 1976; 141–148, July 19, 1976; 89–94, Aug. 2, 1976; 101–108, Aug. 30, 1976; 109–112, Sept. 27, 1976; 119–126, Oct. 25, 1976; 127–133, Nov. 8, 1976).

Process mixing is commonly carried out in pipeline and vessel geometries. The terms **radial mixing** and **axial mixing** are commonly used. Axial mixing refers to mixing of materials which pass a given point at different times, and thus leads to **backmixing.** For example, backmixing or axial mixing occurs in stirred tanks where fluid elements entering the tank at different times are intermingled. Mixing of elements initially at different axial positions in a pipeline is axial mixing. Radial mixing occurs between fluid elements passing a given point at the same time, as, for example, between fluids mixing in a pipeline tee.

Turbulent flow, by means of the chaotic eddy motion associated with velocity fluctuation, is conducive to rapid mixing and, therefore, is the preferred flow regime for mixing. **Laminar mixing** is carried out when high viscosity makes turbulent flow impractical.

Stirred Tank Agitation Turbine impeller agitators, of a variety of shapes, are used for stirred tanks, predominantly in turbulent flow. Figure 6-39 shows typical stirred tank configurations and time-averaged flow patterns for axial flow and radial flow impellers. In order to prevent formation of a **vortex,** four vertical baffles are normally installed. These cause top-to-bottom mixing and prevent mixing-ineffective swirling motion.

For a given impeller and tank geometry, the impeller Reynolds number determines the flow pattern in the tank:

$$\mathrm{Re}_I = \frac{D^2 N \rho}{\mu} \tag{6-155}$$

where D = impeller diameter, N = rotational speed, and ρ and μ are the liquid density and viscosity. Rotational speed N is typically reported in revolutions per minute, or revolutions per second in SI units. Radians per second are almost never used. Typically, $\mathrm{Re}_I > 10^4$ is required for fully turbulent conditions throughout the tank. A wide transition region between laminar and turbulent flow occurs over the range $10 < \mathrm{Re}_I < 10^4$.

The power P drawn by the impeller is made dimensionless in a group called the power number:

$$\mathrm{N}_P = \frac{P}{\rho N^3 D^5} \tag{6-156}$$

Figure 6-40 shows power number vs. impeller Reynolds number for a typical configuration. The similarity to the friction factor vs. Reynolds number behavior for pipe flow is significant. In laminar flow, the power number is inversely proportional to Reynolds number, reflecting the dominance of viscous forces over inertial forces. In

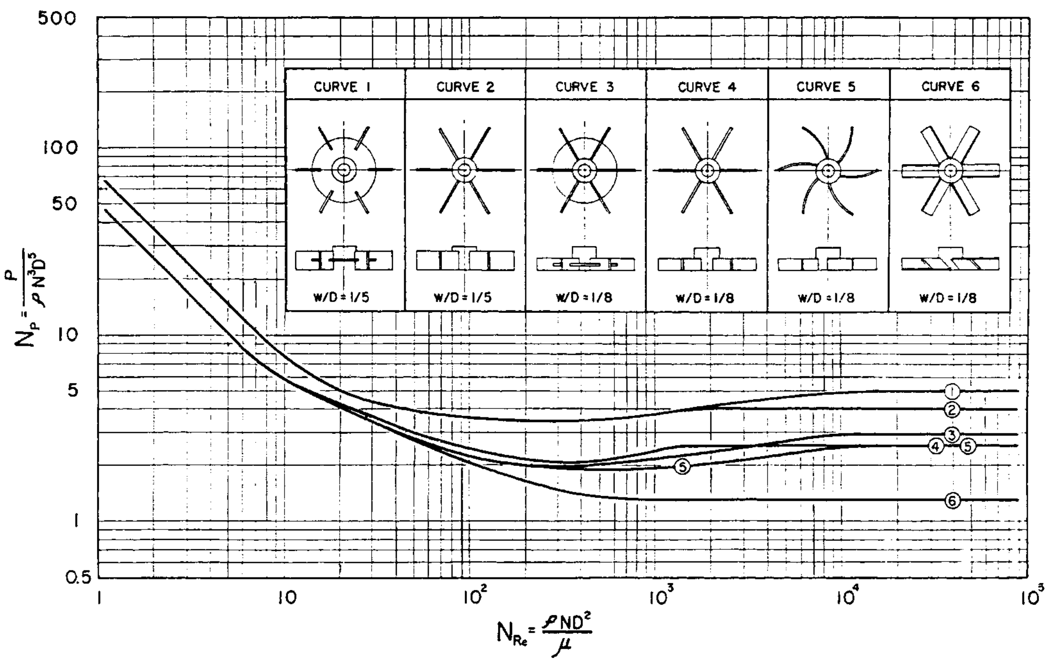

FIG. 6-40 Dimensionless power number in stirred tanks. (*Reprinted with permission from Bates, Fondy, and Corpstein,* Ind. Eng. Chem. Process Design Develop., **2,** *310* [*1963*].)

turbulent flow, where inertial forces dominate, the power number is nearly constant.

Impellers are sometimes viewed as pumping devices; the total volumetric flow rate Q discharged by an impeller is made dimensionless in a pumping number:

$$N_Q = \frac{Q}{ND^3} \tag{6-157}$$

Blend time t_b, the time required to achieve a specified maximum standard deviation of concentration after injection of a tracer into a stirred tank, is made dimensionless by multiplying by the impeller rotational speed:

$$N_b = t_b N \tag{6-158}$$

Dimensionless pumping number and blend time are independent of Reynolds number under fully turbulent conditions. The magnitude of concentration fluctuations from the final well-mixed value in batch mixing decays exponentially with time.

The design of mixing equipment depends on the desired process result. There is often a tradeoff between operating cost, which depends mainly on power, and capital cost, which depends on agitator size and torque. For some applications bulk flow throughout the vessel is desired, while for others high local turbulence intensity is required. Multiphase systems introduce such design criteria as solids suspension and gas dispersion. In very viscous systems, helical ribbons, extruders, and other specialized equipment types are favored over turbine agitators.

Pipeline Mixing Mixing may be carried out with **mixing tees, inline** or **motionless mixing elements,** or in empty pipe. In the latter case, large pipe lengths may be required to obtain adequate mixing. Coaxially injected streams require lengths on the order of 100 pipe diameters. Coaxial mixing in turbulent single-phase flow is characterized by the turbulent diffusivity (eddy diffusivity) D_E which determines the rate of radial mixing. Davies (*Turbulence Phenomena,* Academic, New York, 1972) provides an equation for D_E which may be rewritten as

$$D_E \sim 0.015 DV \text{Re}^{-0.125} \tag{6-159}$$

where D = pipe diameter
V = average velocity
Re = pipe Reynolds number, $DV\rho/\mu$
ρ = density
μ = viscosity

Properly designed tee mixers, with due consideration given to main stream and injected stream momentum, are capable of producing high degrees of uniformity in just a few diameters. Forney (*Jet Injection for Optimum Pipeline Mixing,* in "Encyclopedia of Fluid Mechanics," vol. 2., Chap. 25, Gulf Publishing, 1986) provides a thorough discussion of tee mixing. Inline or motionless mixers are generally of proprietary commercial design, and may be selected for viscous or turbulent, single or multiphase mixing applications. They substantially reduce required pipe length for mixing.

TUBE BANKS

Pressure drop across tube banks may not be correlated by means of a single, simple friction factor—Reynolds number curve, owing to the variety of tube configurations and spacings encountered, two of which are shown in Fig. 6-41. Several investigators have allowed for configuration and spacing by incorporating spacing factors in their friction factor expressions or by using multiple friction factor plots. Commercial computer codes for heat-exchanger design are available which include features for estimating pressure drop across tube banks.

Turbulent Flow The correlation by Grimison (*Trans. ASME,* **59,** 583–594 [1937]) is recommended for predicting pressure drop for turbulent flow (Re ≥ 2,000) across staggered or in-line tube banks for tube spacings [(a/D_t), (b/D_t)] ranging from 1.25 to 3.0. The pressure drop is given by

$$\Delta p = \frac{4fN_r\rho V_{max}^2}{2} \tag{6-160}$$

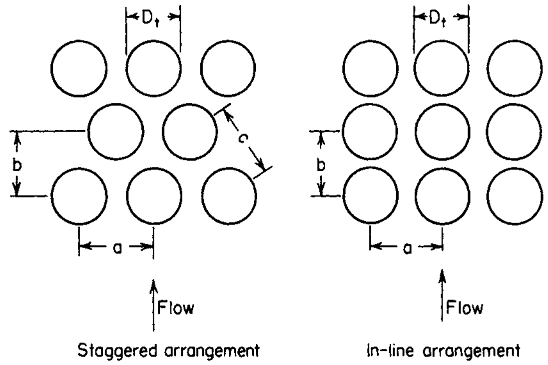

FIG. 6-41 Tube-bank configurations.

where f = friction factor
N_r = number of rows of tubes in the direction of flow
ρ = fluid density
V_{max} = fluid velocity through the minimum area available for flow

For banks of **staggered tubes,** the friction factor for isothermal flow is obtained from Fig. (6-42). Each "fence" (group of parametric curves) represents a particular Reynolds number defined as

$$\text{Re} = \frac{D_t V_{max} \rho}{\mu} \tag{6-161}$$

where D_t = tube outside diameter and μ = fluid viscosity. The numbers along each fence represent the transverse and inflow-direction spacings. The upper chart is for the case in which the minimum area for flow is in the transverse openings, while the lower chart is for the case in which the minimum area is in the diagonal openings. In the latter case, V_{max} is based on the area of the diagonal openings and N_r is the number of rows in the direction of flow minus 1. A critical comparison of this method with all the data available at the time showed an average deviation of the order of ±15 percent (Boucher and Lapple, *Chem. Eng. Prog.,* **44,** 117–134 [1948]). For tube spacings greater than 3 tube diameters, the correlation by Gunter and Shaw (*Trans. ASME,* **67,** 643–660 [1945]) can be used as an approximation. As an **approximation,** the pressure drop can be taken as 0.72 velocity head (based on V_{max} per row of tubes for tube spacings commonly encountered in practice (Lapple, et al., *Fluid and Particle Mechanics,* University of Delaware, Newark, 1954).

For banks of **in-line tubes,** f for isothermal flow is obtained from Fig. 6-43. Average deviation from available data is on the order of ±15 percent. For tube spacings greater than $3D_t$, the charts of Gram, Mackey, and Monroe (*Trans. ASME,* **80,** 25–35 [1958]) can be used. As an **approximation,** the pressure drop can be taken as 0.32 velocity head (based on V_{max}) per row of tubes (Lapple, et al., *Fluid and Particle Mechanics,* University of Delaware, Newark, 1954).

For turbulent flow through **shallow** tube banks, the average friction factor per row will be somewhat greater than indicated by Figs. 6-42 and 6-43, which are based on 10 or more rows depth. A 30 percent increase per row for 2 rows, 15 percent per row for 3 rows, and 7 percent per row for 4 rows can be taken as the maximum likely to be encountered (Boucher and Lapple, *Chem. Eng. Prog.,* **44,** 117–134 [1948]).

For a **single row of tubes,** the friction factor is given by Curve B in Fig. 6-44 as a function of tube spacing. This curve is based on the data of several experimenters, all adjusted to a Reynolds number of 10,000. The values should be substantially independent of Re for 1,000 < Re < 100,000.

For **extended surfaces,** which include fins mounted perpendicularly to the tubes or spiral-wound fins, pin fins, plate fins, and so on, friction data for the specific surface involved should be used. For

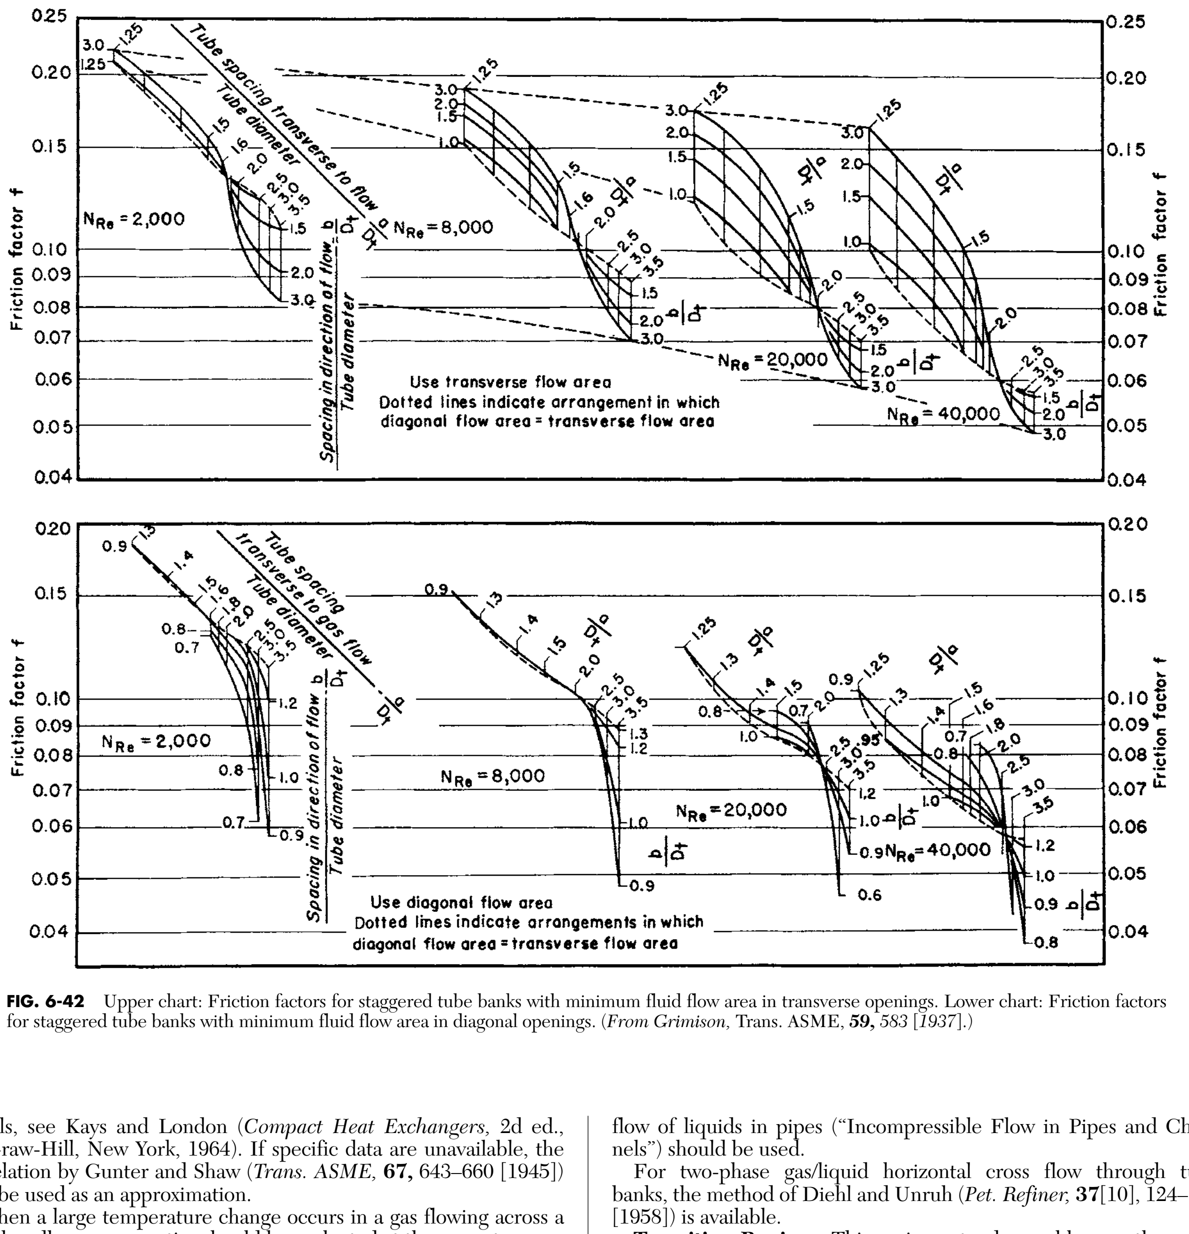

FIG. 6-42 Upper chart: Friction factors for staggered tube banks with minimum fluid flow area in transverse openings. Lower chart: Friction factors for staggered tube banks with minimum fluid flow area in diagonal openings. (*From Grimison,* Trans. ASME, **59,** *583* [*1937*].)

details, see Kays and London (*Compact Heat Exchangers,* 2d ed., McGraw-Hill, New York, 1964). If specific data are unavailable, the correlation by Gunter and Shaw (*Trans. ASME,* **67,** 643–660 [1945]) may be used as an approximation.

When a large temperature change occurs in a gas flowing across a tube bundle, gas properties should be evaluated at the mean temperature

$$T_m = T_t + K\,\Delta T_{lm} \tag{6-162}$$

where T_t = average tube-wall temperature
K = constant
ΔT_{lm} = log-mean temperature difference between the gas and the tubes

Values of K averaged from the recommendations of Chilton and Genereaux (*Trans. AIChE,* **29,** 151–173 [1933]) and Grimison (*Trans. ASME,* **59,** 583–594 [1937]) are as follows: for in-line tubes, 0.9 for cooling and −0.9 for heating; for staggered tubes, 0.75 for cooling and −0.8 for heating.

For nonisothermal flow of **liquids** across tube bundles, the friction factor is increased if the liquid is being cooled and decreased if the liquid is being heated. The factors previously given for nonisothermal flow of liquids in pipes ("Incompressible Flow in Pipes and Channels") should be used.

For two-phase gas/liquid horizontal cross flow through tube banks, the method of Diehl and Unruh (*Pet. Refiner,* **37**[10], 124–128 [1958]) is available.

Transition Region This region extends roughly over the range 200 < Re < 2,000. Figure 6-45 taken from Bergelin, Brown, and Doberstein (*Trans. ASME,* **74,** 953–960 [1952]) gives curves for friction factor f_T for five different configurations. Pressure drop for liquid flow is given by

$$\Delta p = \frac{4 f_T N_r \rho V_{\max}^2}{2}\left(\frac{\mu_s}{\mu_b}\right)^{0.14} \tag{6-163}$$

where N_r = number of major restrictions encountered in flow through the bank (equal to number of rows when minimum flow area occurs in transverse openings, and to number of rows minus 1 when it occurs in the diagonal openings); ρ = fluid density; $V_{\max}$ = velocity through minimum flow area; μ_s = fluid viscosity at tube-surface temperature and μ_b = fluid viscosity at average bulk temperature. This method gives the friction factor within about ±25 percent.

Laminar Region Bergelin, Colburn, and Hull (*Univ. Delaware Eng. Exp. Sta. Bull.,* **2** [1950]) recommend the following equations for

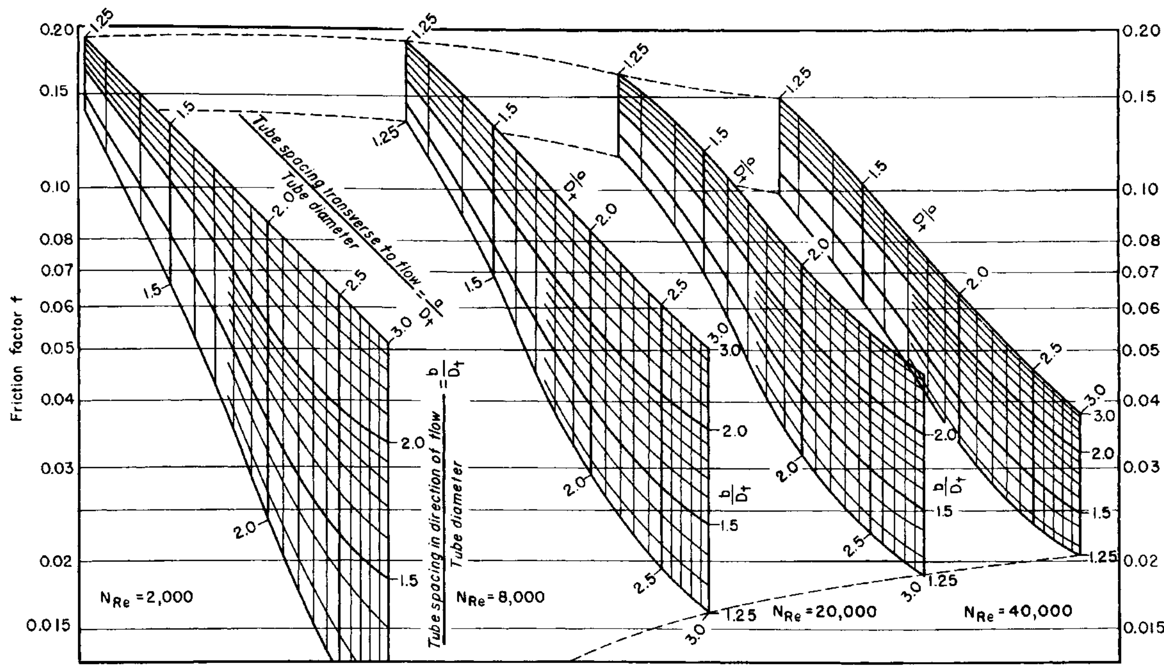

FIG. 6-43 Friction factors for in-line tube banks. (*From Grimison,* Trans. ASME, ***59,*** *583* [*1937*].)

pressure drop with laminar flow ($Re_v < 100$) of liquids across banks of plain tubes with pitch ratios P/D_t of 1.25 and 1.50:

$$\Delta p = \frac{280N_r}{\text{Re}_v}\left(\frac{D_t}{P}\right)^{1.6}\left(\frac{\mu_s}{\mu_b}\right)^m\left(\frac{\rho V_{max}^2}{2}\right) \tag{6-164}$$

$$m = \frac{0.57}{(\text{Re}_v)^{0.25}} \tag{6-165}$$

where $Re_v = D_v V_{max}\rho/\mu_b$; D_v = volumetric hydraulic diameter [(4 × free-bundle volume)/(exposed surface area of tubes)]; P = pitch (= a for in-line arrangements, = a or c [whichever is smaller] for staggered arrangements), and other quantities are as defined following Eq. (6-163). Bergelin, et al. (ibid.) show that pressure drop per row is independent of the number of rows in the bank with laminar flow. The pressure drop is predicted within about ±25 percent.

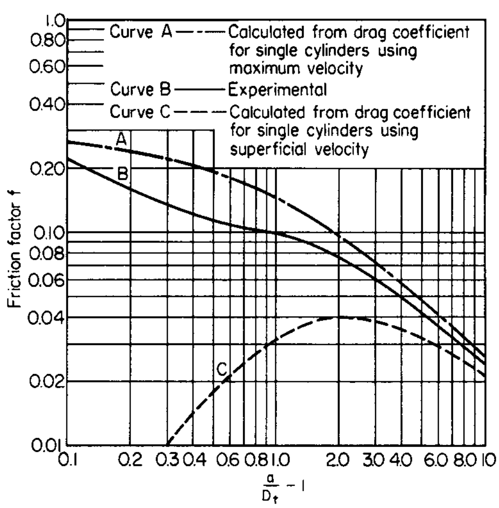

FIG. 6-44 Friction factors vs. transverse spacing for single row of tubes. (*From Boucher and Lapple,* Chem. Eng. Prog., ***44,*** *117* [*1948*].)

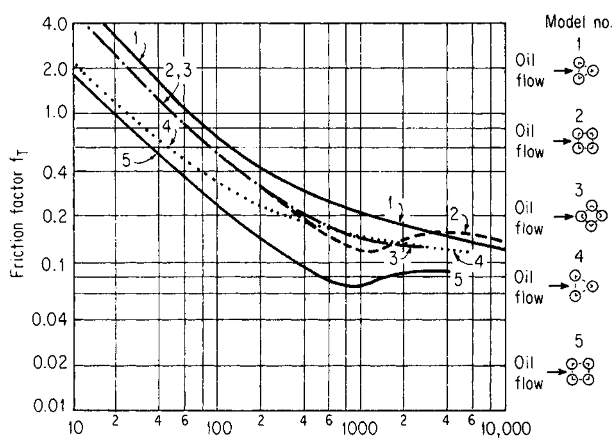

Model	Rows	D_t, in	Pitch/D_t
1	10	¾	1.25
2	10	⅜	1.25
3	14	¾	1.25
4	10	¾	1.50
5	10	⅜	1.50

FIG. 6-45 Friction factors for transition region flow across tube banks. (Pitch is the minimum center-to-center tube spacing.) (*From Bergelin, Brown, and Doberstein,* Trans. ASME, ***74,*** *953* [*1952*].)

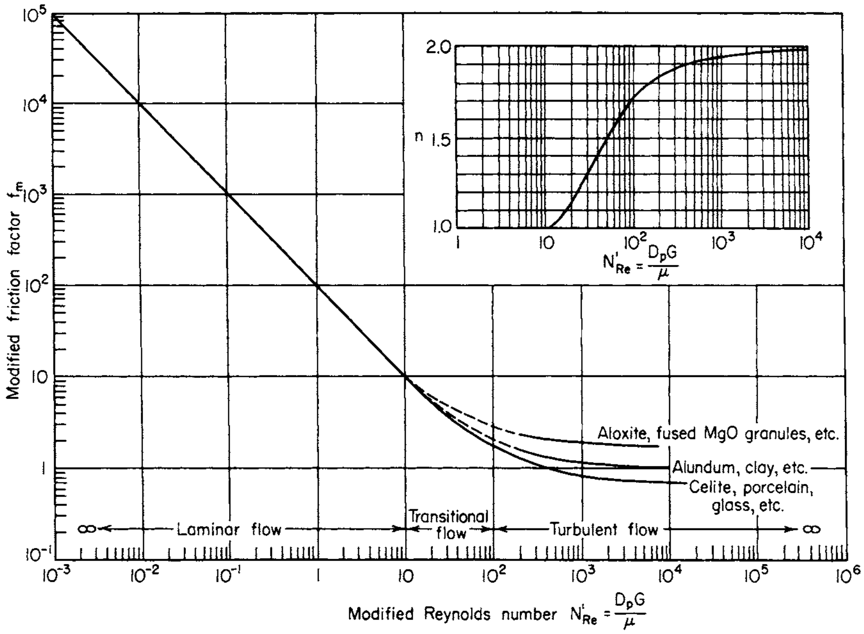

FIG. 6-46 Friction factor for beds of solids. (*From Leva,* Fluidization, *McGraw-Hill, New York, 1959, p. 49.*)

The validity of extrapolating Eq. (6-164) to pitch ratios larger than 1.50 is unknown. The correlation of Gunter and Shaw (*Trans. ASME,* **67,** 643–660 [1945]) may be used as an approximation in such cases.

For laminar flow of non-Newtonian fluids across tube banks, see Adams and Bell (*Chem. Eng. Prog.,* **64,** *Symp. Ser.,* **82,** 133–145 [1968]).

Flow-induced **tube vibration** occurs at critical fluid velocities through tube banks, and is to be avoided because of the severe damage that can result. Methods to predict and correct vibration problems may be found in Eisinger (*Trans. ASME J. Pressure Vessel Tech.,* **102,** 138–145 [May 1980]) and Chen (*J. Sound Vibration,* **93,** 439–455 [1984]).

BEDS OF SOLIDS

Fixed Beds of Granular Solids Pressure-drop prediction is complicated by the variety of granular materials and of their packing arrangement. For flow of a **single incompressible fluid** through an incompressible bed of granular solids, the pressure drop may be estimated by the correlation given in Fig. 6-46 (Leva, *Chem. Eng.,* **56**[5], 115–117 [1949]), or *Fluidization,* McGraw-Hill, New York, 1959). The modified friction factor and Reynolds number are defined by

$$f_m \equiv \frac{D_p \rho \phi_s^{3-n} \epsilon^3 |\Delta p|}{2G^2 L (1-\epsilon)^{3-n}} \tag{6-166}$$

$$\text{Re}' \equiv \frac{D_p G}{\mu} \tag{6-167}$$

where $-\Delta p$ = pressure drop
L = depth of bed
D_p = average particle diameter, defined as the diameter of a sphere of the same volume as the particle
ϵ = void fraction
n = exponent given in Fig. 6-46 as a function of Re′
ϕ_s = shape factor defined as the area of sphere of diameter D_p divided by the actual surface area of the particle
G = fluid superficial mass velocity based on the empty chamber cross section
ρ = fluid density
μ = fluid viscosity

As for any incompressible single-phase flow, the equivalent pressure $P = p + \rho g z$ where g = acceleration of gravity z = elevation, may be used in place of p to account for gravitational effects in flows with vertical components.

In creeping flow (Re′ < 10),

$$f_m = \frac{100}{\text{Re}'} \tag{6-168}$$

At high Reynolds numbers the friction factor becomes nearly constant, approaching a value of the order of unity for most packed beds.

In terms of S, particle surface area per unit volume of bed,

$$D_p = \frac{6(1-\epsilon)}{\phi_s S} \tag{6-169}$$

Porous Media Packed beds of granular solids are one type of the general class referred to as **porous media,** which include geological formations such as petroleum reservoirs and aquifers, manufactured materials such as sintered metals and porous catalysts, burning coal or char particles, and textile fabrics, to name a few. Pressure drop for incompressible flow across a porous medium has the same qualitative behavior as that given by Leva's correlation in the preceding. At low Reynolds numbers, viscous forces dominate and pressure drop is proportional to fluid viscosity and superficial velocity, and at high Reynolds numbers, pressure drop is proportional to fluid density and to the square of superficial velocity.

Creeping flow (Re′ <~ 1) through porous media is often described in terms of the **permeability** k and Darcy's law:

$$\frac{-\Delta P}{L} = \frac{\mu}{k} V \tag{6-170}$$

where V = superficial velocity. The SI units for permeability are m^2. Creeping flow conditions generally prevail in geological porous media. For **multidimensional flows** through **isotropic** porous media, the superficial velocity **V** and pressure gradient ∇P vectors replace the corresponding one-dimensional variables in Eq. (6-170).

$$\nabla P = -\frac{\mu}{k} \mathbf{V} \tag{6-171}$$

For isotropic homogeneous porous media (uniform permeability and porosity), the pressure for creeping incompressible single phase-flow may be shown to satisfy the LaPlace equation:

$$\nabla^2 P = 0 \tag{6-172}$$

For **anisotropic** or **oriented** porous media, as are frequently found in geological media, permeability varies with direction and a **permeability tensor K,** with nine components K_{ij} giving the velocity compenent in the i direction due to a pressure gradient in the j direction, may be introduced. For further information, see Slattery (*Momentum, Energy and Mass Transfer in Continua,* Krieger, Huntington, New York, 1981, pp. 193–218). See also Dullien (*Chem. Eng. J.* [*Laussanne*], **10,** 1,034 [1975]) for a review of pressure-drop methods in single-phase flow. Solutions for Darcy's law for several geometries of interest in petroleum reservoirs and aquifers, for both incompressible and compressible flows, are given in Craft and Hawkins (*Applied Petroleum Reservoir Engineering,* Prentice-Hall, Englewood Cliffs, N.J., 1959). See also Todd (*Groundwater Hydrology,* 2nd ed., Wiley, New York, 1980).

For granular solids of **mixed sizes** the average particle diameter may be calculated as

$$\frac{1}{D_p} = \sum_i \frac{x_i}{D_{p,i}} \tag{6-173}$$

where x_i = weight fraction of particles of size $D_{p,i}$.

For **isothermal compressible flow** of a gas with constant compressibility factor Z through a packed bed of granular solids, an equation similar to Eq. (6-114) for pipe flow may be derived:

$$p_1^2 - p_2^2 = \frac{2ZRG^2T}{M_w}\left[\ln\frac{v_2}{v_1} + \frac{2f_mL(1-\epsilon)^{3-n}}{\phi_s^{3-n}\epsilon^3 D_p}\right] \tag{6-174}$$

where p_1 = upstream absolute pressure
p_2 = downstream absolute pressure
R = gas constant
T = absolute temperature
M_w = molecular weight
v_1 = upstream specific volume of gas
v_2 = downstream specific volume of gas

For creeping flow of **power law** non-Newtonian fluids, the method of Christopher and Middleton (*Ind. Eng. Chem. Fundam.,* **4,** 422–426 [1965]) may be used:

$$-\Delta p = \frac{150HLV^n(1-\epsilon)^2}{D_p^2\phi_s^2\epsilon^3} \tag{6-175}$$

$$H = \frac{K}{12}\left(9 + \frac{3}{n}\right)^n \left[\frac{D_p^2\phi_s^2\epsilon^4}{(1-\epsilon)^2}\right]^{(1-n)/2} \tag{6-176}$$

where $V = G/\rho$ = superficial velocity, K, n = power law material constants, and all other variables are as defined in Eq. (6-166). This correlation is supported by data from Christopher and Middleton (ibid.), Gregory and Griskey (*AIChE J.,* **13,** 122–125 [1967]), Yu, Wen, and Bailie (*Can. J. Chem. Eng.,* **46,** 149–154 [1968]), Siskovic, Gregory, and Griskey (*AIChE J.,* **17,** 176–187 [1978]), Kemblowski and Mertl (*Chem. Eng. Sci.,* **29,** 213–223 [1974]), and Kemblowski and Dziuminski (*Rheol. Acta,* **17,** 176–187 [1978]). The measurements cover the range n = 0.50 to 1.60, and modified Reynolds number $\text{Re}' = 10^{-8}$ to 10, where

$$\text{Re}' = \frac{D_p V^{2-n}\rho}{H} \tag{6-177}$$

For the case $n = 1$ (Newtonian fluid), Eqs. (6-175) and (6-176) give a pressure drop 25 percent less than that given by Eqs. (6-166) through (6-168).

For **viscoelastic fluids** see Marshall and Metzner (*Ind. Eng. Chem. Fundam.,* **6,** 393–400 [1967]), Siskovic, Gregory, and Griskey (*AIChE J.,* **13,** 122–125 [1967]) and Kemblowski and Dziubinski (*Rheol. Acta,* **17,** 176–187 [1978]).

For gas flow through porous media with small pore diameters, the slip flow and molecular flow equations previously given (see the "Vacuum Flow" subsection) may be applied when the pore is of the same or smaller order as the mean free path, as described by Monet and Vermeulen (*Chem. Eng. Prog.,* **55,** *Symp. Ser.,* **25** [1959]).

Tower Packings For the flow of a **single fluid** through a bed of tower packing, pressure drop may be estimated using the preceding methods. See also Sec. 14 of this *Handbook.* For **countercurrent gas/liquid flow** in commercial tower packings, both structured and unstructured, several sources of data and correlations for pressure drop and flooding are available. See, for example, Strigle (*Random Packings and Packed Towers, Design and Applications,* Gulf Publishing, Houston, 1989; *Chem. Eng. Prog.,* **89**[8], 79–83 [August 1993]), Hughmark (*Ind. Eng. Chem. Fundam.,* **25,** 405–409 [1986]), Chen (*Chem. Eng. Sci.,* **40,** 2139–2140 [1985]), Billet and Mackowiak (*Chem. Eng. Technol.,* **11,** 213–217 [1988]), Krehenwinkel and Knapp (*Chem. Eng. Technol.,* **10,** 231–242 [1987]), Mersmann and Deixler (*Ger. Chem. Eng.,* **9,** 265–276 [1986]), and Robbins (*Chem. Eng. Progr.,* **87**[5], 87–91 [May 1991]). Data and correlations for flooding and pressure drop for structured packings are given by Fair and Bravo (*Chem. Eng. Progr.,* **86**[1], 19–29 [January 1990]).

Fluidized Beds When gas or liquid flows upward through a vertically unconstrained bed of particles, there is a minimum fluid velocity at which the particles will begin to move. Above this minimum velocity, the bed is said to be *fluidized.* Fluidized beds are widely used, in part because of their excellent mixing and heat and mass transfer characteristics. See Sec. 17 of this *Handbook* for detailed information.

BOUNDARY LAYER FLOWS

Boundary layer flows are a special class of flows in which the flow far from the surface of an object is inviscid, and the effects of viscosity are manifest only in a thin region near the surface where steep velocity gradients occur to satisfy the no-slip condition at the solid surface. The thin layer where the velocity decreases from the inviscid, potential flow velocity to zero (relative velocity) at the solid surface is called the *boundary layer.* The thickness of the boundary layer is indefinite because the velocity asymptotically approaches the free-stream velocity at the outer edge. The boundary layer thickness is conventionally taken to be the distance for which the velocity equals 0.99 times the free-stream velocity. The boundary layer may be either laminar or turbulent. Particularly in the former case, the equations of motion may be simplified by scaling arguments. Schlichting (*Boundary Layer Theory,* 8th ed., McGraw-Hill, New York, 1987) is the most comprehensive source for information on boundary layer flows.

Flat Plate, Zero Angle of Incidence For flow over a wide, thin flat plate at zero angle of incidence with a uniform free-stream velocity, as shown in Fig. 6-47, the **critical Reynolds number** at which the boundary layer becomes turbulent is normally taken to be

$$\text{Re}_x = \frac{xV\rho}{\mu} = 500{,}000 \tag{6-178}$$

where V = free-stream velocity
ρ = fluid density
μ = fluid viscosity
x = distance from leading edge of the plate

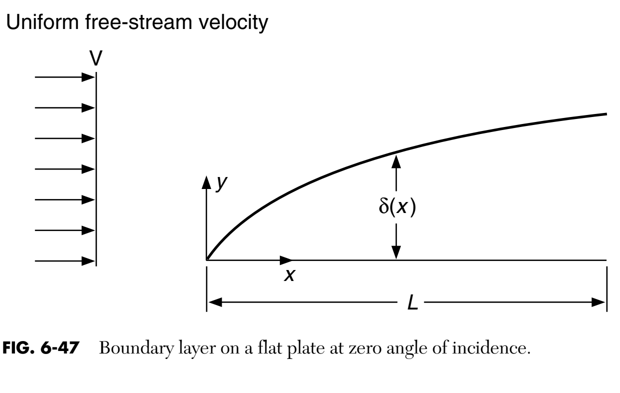

FIG. 6-47 Boundary layer on a flat plate at zero angle of incidence.

However, the transition Reynolds number depends on free-stream turbulence and may range from 3×10^5 to 3×10^6. The **laminar boundary layer** thickness δ is a function of distance from the leading edge:

$$\delta \approx 5.0x\mathrm{Re}_x^{-0.5} \qquad (6\text{-}179)$$

The total drag on the plate of length L and width b for a laminar boundary layer, including the drag on both surfaces, is:

$$F_D = 1.328bL\rho V^2\mathrm{Re}_L^{-0.5} \qquad (6\text{-}180)$$

For **non-Newtonian power law fluids** (Acrivos, Shah, and Peterson, *AIChE J.*, **6,** 312–317 [1960]; Hsu, *AIChE J.*, **15,** 367–370 [1969]),

$$F_D = CbL\rho V^2\mathrm{Re}_L'^{-1/(1+n)} \qquad (6\text{-}181)$$

$n =$	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1
$C =$	2.075	1.958	1.838	1.727	1.627	1.538	1.460	1.390	1.328

where $\mathrm{Re}_L' = \rho V^{2-n}L^n/K$ and K and n are the power law material constants (see Eq. [6-4]).

For a **turbulent boundary layer,** the thickness may be estimated as

$$\delta \approx 0.37x\mathrm{Re}_x^{-0.2} \qquad (6\text{-}182)$$

and the total drag force on both sides of the plate of length L is

$$F_D = \left[\frac{0.455}{(\log \mathrm{Re}_L)^{2.58}} - \frac{1{,}700}{\mathrm{Re}_L}\right]\rho bLV^2 \qquad 5 \times 10^5 < \mathrm{Re}_L < 10^9 \qquad (6\text{-}183)$$

Here the second term accounts for the laminar leading edge of the boundary layer and assumes that the critical Reynolds number is 500,000.

Cylindrical Boundary Layer Laminar boundary layers on cylindrical surfaces, with flow parallel to the cylinder axis, are described by Glauert and Lighthill (*Proc. R. Soc.* [*London*], **230A,** 188–203 [1955]), Jaffe and Okamura (*Z. Angew. Math. Phys.*, **19,** 564–574 [1968]), and Stewartson (*Q. Appl. Math.*, **13,** 113–122 [1955]). For a turbulent boundary layer, the total drag may be estimated as

$$F_D = \overline{c_f}\pi rL\rho V^2 \qquad (6\text{-}184)$$

where r = cylinder radius, L = cylinder length, and the average friction coefficient is given by (White, *J. Basic Eng.*, **94,** 200–206 [1972])

$$\overline{c_f} = 0.0015 + \left[0.30 + 0.015\left(\frac{L}{r}\right)^{0.4}\right]\mathrm{Re}_L^{-1/3} \qquad (6\text{-}185)$$

for $\mathrm{Re}_L = 10^6$ to 10^9 and $L/r < 10^6$.

Continuous Flat Surface Boundary layers on continuous surfaces drawn through a stagnant fluid are shown in Fig. 6-48. Figure 6-48*a* shows the continuous flat surface (Sakiadis, *AIChE J.*, **7,** 26–28, 221–225, 467–472 [1961]). The critical Reynolds number for transition to turbulent flow may be greater than the 500,000 value for the finite flat-plate case discussed previously (Tsou, Sparrow, and Kurtz, *J. Fluid Mech.*, **26,** 145–161 [1966]). For a laminar boundary layer, the thickness is given by

$$\delta = 6.37x\mathrm{Re}_x^{-0.5} \qquad (6\text{-}186)$$

and the total drag exerted on the two surfaces is

$$F_D = 1.776bL\rho V^2\mathrm{Re}_L^{-0.5} \qquad (6\text{-}187)$$

The total flow rate of fluid entrained by the surface is

$$q = 3.232bLV\mathrm{Re}_L^{-0.5} \qquad (6\text{-}188)$$

The theoretical velocity field was experimentally verified by Tsou, Sparrow, and Goldstein (*Int. J. Heat Mass Transfer,* **10,** 219–235 [1967]) and Szeri, Yates, and Hai (*J. Lubr. Technol.*, **98,** 145–156 [1976]). For **non-Newtonian power law fluids** see Fox, Erickson, and Fan (*AIChE J.*, **15,** 327–333 [1969]).

For a turbulent boundary layer, the thickness is given by

$$\delta = 1.01x\mathrm{Re}_x^{-0.2} \qquad (6\text{-}189)$$

and the total drag on both sides by

$$F_D = 0.056bL\rho V^2\mathrm{Re}_L^{-0.2} \qquad (6\text{-}190)$$

and the total entrainment by

$$q = 0.252bLV\mathrm{Re}_L^{-0.2} \qquad (6\text{-}191)$$

When the laminar boundary layer is a significant part of the total length of the object, the total drag should be corrected by subtracting a calculated turbulent drag for the length of the laminar section and then adding the laminar drag for the laminar section. Tsou, Sparrow, and Goldstein (*Int. J. Heat Mass Transfer,* **10,** 219–235 [1967]) give an improved analysis of the turbulent boundary layer; their data indicate that Eq. (6-190) underestimates the drag by about 15 percent.

Continuous Cylindrical Surface The continuous surface shown in Fig. 6-48*b* is applicable, for example, for a wire drawn through a stagnant fluid (Sakiadis, *AIChE J.*, **7,** 26–28, 221–225, 467–472 [1961]); Vasudevan and Middleman, *AIChE J.*, **16,** 614 [1970]). The critical-length Reynolds number for transition is $\mathrm{Re}_x = 200{,}000$. The laminar boundary layer thickness, total drag, and entrainment flow rate may be obtained from Fig. 6-49. The normalized boundary layer thickness and integral friction coefficient are from Vasudevan and Middleman, who used a similarity solution of the boundary layer equations. The drag force over a length x is given by

$$F_D = \overline{C_f}x\,\frac{\rho V^2}{2}\,2\pi r_o \qquad (6\text{-}192)$$

The entrainment flow rate is from Sakiadis, who used an integral momentum approximation rather than the exact similarity solution.

$$q = V\Delta \qquad (6\text{-}193)$$

Further laminar boundary layer analysis is given by Crane (*Z. Angew. Math. Phys.*, **23,** 201–212 [1972]).

For a turbulent boundary layer, the total drag may be roughly estimated using Eqs. (6-184) and (6-185) for finite cylinders. Measured forces by Kwon and Prevorsek (*J. Eng. Ind.*, **101,** 73–79 [1979]) are greater than predicted this way.

The laminar boundary layer on **deforming continuous surfaces** with velocity varying with axial position is discussed by Vleggaar (*Chem. Eng. Sci.*, **32,** 1517–1525 [1977] and Crane (*Z. Angew. Math. Phys.*, **26,** 619–622 [1975]).

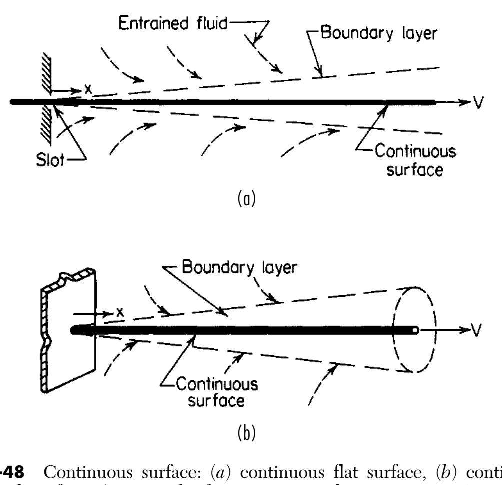

FIG. 6-48 Continuous surface: (*a*) continuous flat surface, (*b*) continuous cylindrical surface. (*From Sakiadis,* Am. Inst. Chem. Eng. J., **7,** *221, 467* [*1961*].)

VORTEX SHEDDING

When fluid flows past objects or through orifices or similar restrictions, vortices may periodically be shed downstream. Objects such as smokestacks, chemical-processing columns, suspended pipelines, and electrical transmission lines can be subjected to damaging vibrations and forces due to the vortices, especially if the shedding frequency is close to a natural vibration frequency of the object. The shedding can

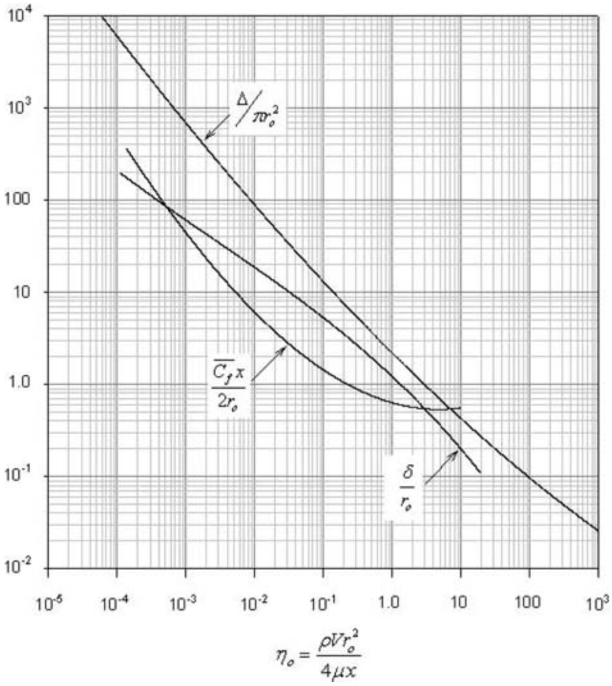

FIG 6-49 Boundary layer parameters for continuous cylindrical surfaces. ($\Delta/\pi r_o^2$ *is from Sakiadis,* Am. Inst. Chem. Engr. J., **7,** *467 [1961];* $\overline{C_f}x/2r_o$ and δ/r_o *are from Vasudevan and Middleman*, Am. Inst. Chem. Eng. J., ***16****, 614 [1970].*)

also produce sound. See Krzywoblocki (*Appl. Mech. Rev.,* **6,** 393–397 [1953]) and Marris (*J. Basic Eng.,* **86,** 185–196 [1964]).

Development of a vortex street, or *von Kármán vortex street* is shown in Fig. 6-50. Discussions of the vortex street may be found in Panton (pp. 387–393). The Reynolds number is

$$\text{Re} = \frac{DV\rho}{\mu} \tag{6-194}$$

where D = diameter of cylinder or effective width of object
V = free-stream velocity
ρ = fluid density
μ = fluid viscosity

For flow past a cylinder, the vortex street forms at Reynolds numbers above about 40. The vortices initially form in the wake, the point of formation moving closer to the cylinder as Re is increased. At a Reynolds number of 60 to 100, the vortices are formed from eddies attached to the cylinder surface. The vortices move at a velocity slightly less than V. The frequency of vortex shedding f is given in terms of the Strouhal number, which is approximately constant over a wide range of Reynolds numbers.

$$\text{St} \equiv \frac{fD}{V} \tag{6-195}$$

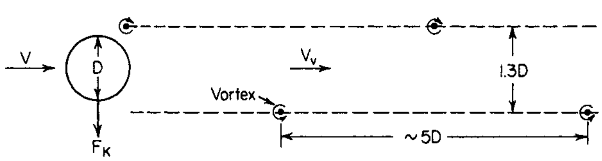

FIG. 6-50 Vortex street behind a cylinder.

For 40 < Re < 200 the vortices are laminar and the Strouhal number has a nearly constant value of 0.2 for flow past a cylinder. Between Re = 200 and 400 the Strouhal number is no longer constant and the wake becomes irregular. Above about Re = 400 the vortices become turbulent, the wake is once again stable, and the Strouhal number remains constant at about 0.2 up to a Reynolds number of about 10^5. Above Re = 10^5 the vortex shedding is difficult to see in flow visualization experiments, but velocity measurements still show a strong spectral component at St = 0.2 (Panton, p. 392). Experimental data suggest that the vortex street disappears over the range $5 \times 10^5 < \text{Re} < 3.5 \times 10^6$, but is reestablished at above 3.5×10^6 (Schlichting).

Vortex shedding exerts alternating lateral forces on a cylinder, perpendicular to the flow direction. Such forces may lead to severe vibration or mechanical failure of cylindrical elements such as heat-exchanger tubes, transmission lines, stacks, and columns when the vortex shedding frequency is close to resonant bending frequency. According to Den Hartog (*Proc. Nat. Acad. Sci.,* **40,** 155–157 [1954]), the vortex shedding and cylinder vibration frequency will shift to the resonant frequency when the calculated shedding frequency is within 20 percent of the resonant frequency. The well-known Tacoma Narrows bridge collapse resulted from resonance between a torsional oscillation and vortex shedding (Panton, p. 392). Spiral strakes are sometimes installed on tall stacks so that vortices at different axial positions are not shed simultaneously. The alternating lateral force F_K, sometimes called the *von Kármán force,* is given by (Den Hartog, *Mechanical Vibrations,* 4th ed., McGraw-Hill, New York, 1956, pp. 305–309):

$$F_K = C_K A \frac{\rho V^2}{2} \tag{6-196}$$

where C_K = von Kármán coefficient
A = projected area perpendicular to the flow
ρ = fluid density
V = free-stream fluid velocity

For a cylinder, C_K = 1.7. For a vibrating cylinder, the effective projected area exceeds, but is always less than twice, the actual cylinder projected area (Rouse, *Engineering Hydraulics,* Wiley, New York, 1950).

The following references pertain to discussions of vortex shedding in specific structures: steel stacks (Osker and Smith, *Trans. ASME,* **78,** 1381–1391 [1956]; Smith and McCarthy, *Mech. Eng.,* **87,** 38–41 [1965]); chemical-processing columns (Freese, *J. Eng. Ind.,* **81,** 77–91 [1959]); heat exchangers (Eisinger, *Trans. ASME J. Pressure Vessel Tech.,* **102,** 138–145 [May 1980]; Chen, *J. Sound Vibration,* **93,** 439–455 [1984]; Gainsboro, *Chem. Eng. Prog.,* **64**[3], 85–88 [1968]; "Flow-Induced Vibration in Heat Exchangers," *Symp. Proc.,* ASME, New York, 1970); suspended pipe lines (Baird, *Trans. ASME,* **77,** 797–804 [1955]); and suspended cable (Steidel, *J. Appl. Mech.,* **23,** 649–650 [1956]).

COATING FLOWS

In coating flows, liquid films are entrained on moving solid surfaces. For general discussions, see Ruschak (*Ann. Rev. Fluid Mech.,* **17,** 65–89 [1985]), Cohen and Gutoff (*Modern Coating and Drying Technology,* VCH Publishers, New York, 1992), and Middleman (*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977). It is generally important to control the thickness and uniformity of the coatings.

In **dip coating,** or free withdrawal coating, a solid surface is withdrawn from a liquid pool, as shown in Fig. 6-51. It illustrates many of the features found in other coating flows, as well. Tallmadge and Gutfinger (*Ind. Eng. Chem.,* **59**[11], 19–34 [1967]) provide an early review of the theory of dip coating. The coating flow rate and film thickness are controlled by the withdrawal rate and the flow behavior in the meniscus region. For a withdrawal velocity V and an angle of inclination from the horizontal ϕ, the film thickness h may be

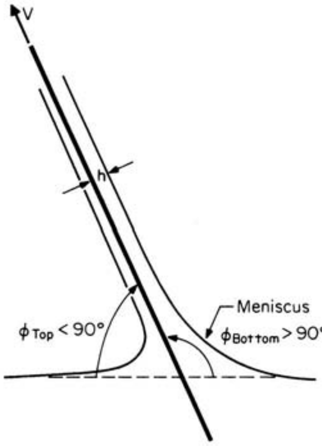

FIG. 6-51 Dip coating.

estimated for low withdrawal velocities by

$$h\left(\frac{\rho g}{\sigma}\right)^{1/2} = \frac{0.944}{(1 - \cos\phi)^{1/2}}\,\text{Ca}^{2/3} \tag{6-197}$$

where g = acceleration of gravity
$\text{Ca} = \mu V/\sigma$ = capillary number
μ = viscosity
σ = surface tension

Equation (6-197) is asymptotically valid as Ca → 0 and agrees with experimental data up to capillary numbers in the range of 0.01 to 0.03. In practice, where high production rates require high withdrawal speeds, capillary numbers are usually too large for Eq. (6-197) to apply. Approximate analytical methods for larger capillary numbers have been obtained by numerous investigators, but none appears wholly satisfactory, and some are based on questionable assumptions (Ruschak, *Ann. Rev. Fluid Mech.,* **17,** 65–89 [1985]). With the availability of high-speed computers and the development of the field of computational fluid dynamics, numerical solutions accounting for two-dimensional flow aspects, along with gravitational, viscous, inertial, and surface tension forces are now the most effective means to analyze coating flow problems.

Other common coating flows include premetered flows, such as **slide** and **curtain coating,** where the film thickness is an independent parameter that may be controlled within limits, and the curvature of the mensiscus adjusts accordingly; the closely related **blade coating;** and **roll coating** and **extrusion coating.** See Ruschak (ibid.), Cohen and Gutoff (*Modern Coating and Drying Technology,* VCH Publishers, New York, 1992), and Middleman (*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977). For dip coating of wires, see Taughy (*Int. J. Numerical Meth. Fluids,* **4,** 441–475 [1984]).

Many coating flows are subject to instabilities that lead to unacceptable coating defects. Three-dimensional flow instabilities lead to such problems as **ribbing.** Air entrainment is another common defect.

FALLING FILMS

Minimum Wetting Rate The minimum liquid rate required for complete wetting of a vertical surface is about 0.03 to 0.3 kg/m · s for water at room temperature. The minimum rate depends on the geometry and nature of the vertical surface, liquid surface tension, and mass transfer between surrounding gas and the liquid. See Ponter, et al. (*Int. J. Heat Mass Transfer,* **10,** 349–359 [1967]; *Trans. Inst. Chem. Eng.* [*London*], **45,** 345–352 [1967]), Stainthorp and Allen (*Trans. Inst. Chem. Eng.* [*London*], **43,** 85–91 [1967]) and Watanabe, et al. (*J. Chem. Eng.* [*Japan*], **8**[1], 75 [1975]).

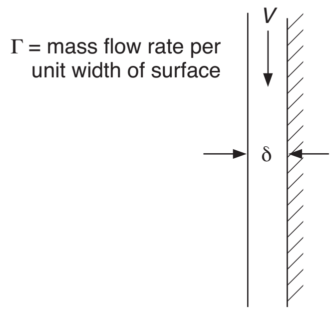

FIG. 6-52 Falling film.

Laminar Flow For films falling down **vertical flat surfaces,** as shown in Fig. 6-52, or vertical tubes with small film thickness compared to tube radius, laminar flow conditions prevail for Reynolds numbers less than about 2,000, where the Reynolds number is given by

$$\text{Re} = \frac{4\Gamma}{\mu} \tag{6-198}$$

where Γ = liquid mass flow rate per unit width of surface and μ = liquid viscosity. For a flat film surface, the following equations may be derived. The film thickness δ is

$$\delta = \left(\frac{3\Gamma\mu}{\rho^2 g}\right)^{1/3} \tag{6-199}$$

The average film velocity is

$$V = \frac{\Gamma}{\rho\delta} = \frac{g\rho\delta^2}{3\mu} \tag{6-200}$$

The downward velocity profile $u(x)$ where $x = 0$ at the solid surface and $x = \delta$ at the liquid/gas interface is given by

$$u = 1.5V\left[\frac{2x}{\delta} - \left(\frac{x}{\delta}\right)^2\right] \tag{6-201}$$

These equations assume that there is no drag force at the gas/liquid interface, such as would be produced by gas flow. For a flat surface **inclined** at an angle θ with the horizontal, the preceding equations may be modified by replacing g by $g \sin\theta$. For films falling inside vertical tubes with film thickness up to and including the full pipe radius, see Jackson (*AIChE J.,* **1,** 231–240 [1955]).

These equations have generally given good agreement with experimental results for low-viscosity liquids (<0.005 Pa · s) (< 5 cP) whereas Jackson (ibid.) found film thicknesses for higher-viscosity liquids (0.01 to 0.02 Pa·s (10 to 20 cP) were significantly less than predicted by Eq. (6-197). At Reynolds numbers of 25 or greater, **surface waves** will be present on the liquid film. West and Cole (*Chem. Eng. Sci.,* **22,** 1388–1389 [1967]) found that the surface velocity $u(x = \delta)$ is still within ±7 percent of that given by Eq. (6-201) even in wavy flow.

For laminar non-Newtonian film flow, see Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977, p. 215, 217), Astarita, Marrucci, and Palumbo (*Ind. Eng. Chem. Fundam.,* **3,** 333–339 [1964]) and Cheng (*Ind. Eng. Chem. Fundam.,* **13,** 394–395 [1974]).

Turbulent Flow In turbulent flow, Re > 2,000, for vertical surfaces, the film thickness may be estimated to within ±25 percent using

$$\delta = 0.304\left(\frac{\Gamma^{1.75}\mu^{0.25}}{\rho^2 g}\right)^{1/3} \tag{6-202}$$

Replace g by $g \sin\theta$ for a surface inclined at angle θ to the horizontal. The average film velocity is $V = \Gamma/\rho\delta$.

Tallmadge and Gutfinger (*Ind. Eng. Chem.*, **59**[11], 19–34 [1967]) discuss prediction of drainage rates from liquid films on flat and cylindrical surfaces.

Effect of Surface Traction If a drag is exerted on the surface of the film because of motion of the surrounding fluid, the film thickness will be reduced or increased, depending upon whether the drag acts with or against gravity. Thomas and Portalski (*Ind. Eng. Chem.*, **50,** 1081–1088 [1958]), Dukler (*Chem. Eng. Prog.*, **55**[10], 62–67 [1959]), and Kosky (*Int. J. Heat Mass Transfer,* **14,** 1220–1224 [1971]) have presented calculations of film thickness and film velocity. Film thickness data for falling water films with cocurrent and countercurrent air flow in pipes are given by Zhivaikin (*Int. Chem. Eng.*, **2,** 337–341 [1962]). Zabaras, Dukler, and Moalem-Maron (*AIChE J.*, **32,** 829–843 [1986]) and Zabaras and Dukler (*AIChE J.*, **34,** 389–396 [1988]) present studies of film flow in vertical tubes with both cocurrent and countercurrent gas flow, including measurements of film thickness, wall shear stress, wave velocity, wave amplitude, pressure drop, and flooding point for countercurrent flow.

Flooding With countercurrent gas flow, a condition is reached with increasing gas rate for which flow reversal occurs and liquid is carried upward. The mechanism for this flooding condition has been most often attributed to waves either bridging the pipe or reversing direction to flow upward at flooding. However, the results of Zabaras and Dukler (ibid.) suggest that flooding may be controlled by flow conditions at the liquid inlet and that wave bridging or upward wave motion does not occur, at least for the 50.8-mm diameter pipe used for their study. Flooding mechanisms are still incompletely understood. Under some circumstances, as when the gas is allowed to develop its normal velocity profile in a "calming length" of pipe beneath the liquid draw-off, the gas superficial velocity at flooding will be increased, and increases with decreasing length of wetted pipe (Hewitt, Lacy, and Nicholls, *Proc. Two-Phase Flow Symp.*, University of Exeter, paper 4H, AERE-4 4614 [1965]). A bevel cut at the bottom of the pipe with an angle 30° from the vertical will increase the flooding velocity in small-diameter tubes at moderate liquid flow rates. If the gas approaches the tube from the side, the taper should be oriented with the point facing the gas entrance. Figures 6-53 and 6-54 give correlations for flooding in tubes with square and slant bottoms (courtesy Holmes, DuPont Co.) The superficial mass velocities of gas and liquid G_G and G_L, and the physical property parameters λ and ψ are the same as those defined for the Baker chart ("Multiphase Flow" subsection, Fig. 6-25). For tubes larger than 50 mm (2 in), flooding velocity appears to be relatively insensitive to diameter and the flooding curves for 1.98-in diameter may be used.

HYDRAULIC TRANSIENTS

Many transient flows of liquids may be analyzed by using the full time-dependent equations of motion for incompressible flow. However, there are some phenomena that are controlled by the small compressibility of liquids. These phenomena are generally called **hydraulic transients.**

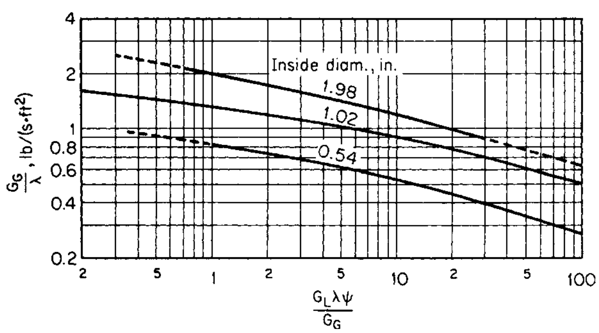

FIG. 6-53 Flooding in vertical tubes with square top and square bottom. To convert lbm/(ft²·s) to kg/(m²·s), multiply by 4.8824; to convert in to mm, multiply by 25.4. (*Courtesy of E. I. du Pont de Nemours & Co.*)

Water Hammer When liquid flowing in a pipe is suddenly decelerated to zero velocity by a fast-closing valve, a pressure wave propagates upstream to the pipe inlet, where it is reflected; a pounding of the line commonly known as **water hammer** is often produced. For an instantaneous flow stoppage of a truly incompressible fluid in an inelastic pipe, the pressure rise would be infinite. Finite compressibility of the fluid and elasticity of the pipe limit the pressure rise to a finite value. The Joukowski formula gives the maximum pressure rise as

$$\Delta p = \rho a \Delta V \tag{6-203}$$

where ρ = liquid density
ΔV = change in liquid velocity
a = pressure wave velocity

The wave velocity is given by

$$a = \frac{\sqrt{\beta/\rho}}{\sqrt{1 + (\beta/E)(D/b)}} \tag{6-204}$$

where β = liquid bulk modulus of elasticity
E = elastic modulus of pipe wall
D = pipe inside diameter
b = pipe wall thickness

The numerator gives the wave velocity for perfectly rigid pipe, and the denominator corrects for wall elasticity. This formula is for thin-walled pipes; for thick-walled pipes, the factor D/b is replaced by

$$2\,\frac{D_o^2 + D_i^2}{D_o^2 - D_i^2}$$

where D_o = pipe outside diameter
D_i = pipe inside diameter

Example 10: Response to Instantaneous Valve Closing Compute the wave speed and maximum pressure rise for instantaneous valve closing, with an initial velocity of 2.0 m/s, in a 4-in Schedule 40 steel pipe with elastic modulus 207×10^9 Pa. Repeat for a plastic pipe of the same dimensions, with $E = 1.4 \times 10^9$ Pa. The liquid is water with $\beta = 2.2 \times 10^9$ Pa and $\rho = 1{,}000$ kg/m³.

For the steel pipe, $D = 102.3$ mm, $b = 6.02$ mm, and the wave speed is

$$a = \frac{\sqrt{\beta/\rho}}{\sqrt{1 + (\beta/E)(D/b)}}$$

$$= \frac{\sqrt{2.2 \times 10^9/1000}}{\sqrt{1 + (2.2 \times 10^9/207 \times 10^9)(102.3/6.02)}}$$

$$= 1365 \text{ m/s}$$

The maximum pressure rise is

$$\Delta p = \rho a \Delta V$$
$$= 1{,}000 \times 1{,}365 \times 2.0 = 2.73 \times 10^6 \text{ Pa}$$

For the plastic pipe,

$$a = \frac{\sqrt{2.2 \times 10^9/1000}}{\sqrt{1 + (2.2 \times 10^9/1.4 \times 10^9)(102.3/6.02)}}$$
$$= 282 \text{ m/s}$$
$$\Delta p = \rho a \Delta V = 1{,}000 \times 282 \times 2.0 = 5.64 \times 10^5 \text{ Pa}$$

The maximum pressure surge is obtained when the valve closes in less time than the period τ required for the pressure wave to travel from the valve to the pipe inlet and back, a total distance of $2L$.

$$\tau = \frac{2L}{a} \tag{6-205}$$

The pressure surge will be reduced when the time of flow stoppage exceeds the pipe period τ, due to cancellation between direct and reflected waves. Wood and Jones (*Proc. Am. Soc. Civ. Eng., J. Hydraul. Div.,* **99,** (HY1), 167–178 [1973]) present charts for reliable estimates of water-hammer pressure for different valve closure modes. Wylie and Streeter (*Hydraulic Transients,* McGraw-Hill, New York, 1978) describe several solution methods for hydraulic transients, including the method of characteristics, which is well suited to computer methods for accurate solutions. A rough approximation for the peak pressure for cases where the valve closure time t_c exceeds the pipe period τ is (Daugherty and Franzini, *Fluid Mechanics with Engineering Applications,* McGraw-Hill, New York, 1985):

$$\Delta p \approx \left(\frac{\tau}{t_c}\right) \rho a \Delta V \tag{6-206}$$

Successive reflections of the pressure wave between the pipe inlet and the closed valve result in alternating pressure increases and decreases, which are gradually attenuated by fluid friction and imperfect elasticity of the pipe. Periods of reduced pressure occur while the reflected pressure wave is traveling from inlet to valve. Degassing of the liquid may occur, as may vaporization if the pressure drops below the vapor pressure of the liquid. Gas and vapor bubbles decrease the wave velocity. Vaporization may lead to what is often called *liquid column separation;* subsequent collapse of the vapor pocket can result in pipe rupture.

In addition to water hammer induced by changes in valve setting, including closure, numerous other hydraulic transient flows are of interest, as, for example (Wylie and Streeter, *Hydraulic Transients,* McGraw-Hill, New York, 1978), those arising from starting or stopping of pumps; changes in power demand from turbines; reciprocating pumps; changing elevation of a reservoir; waves on a reservoir; turbine governor hunting; vibration of impellers or guide vanes in pumps, fans, or turbines; vibration of deformable parts such as valves; draft-tube instabilities due to vortexing; and unstable pump or fan characteristics. Tube failure in heat exhangers may be added to this list.

Pulsating Flow Reciprocating machinery (pumps and compressors) produces flow pulsations, which adversely affect flow meters and process control elements and can cause vibration and equipment failure, in addition to undesirable process results. Vibration and damage can result not only from the fundamental frequency of the pulse producer but also from higher harmonics. Multipiston double-acting units reduce vibrations. Pulsation dampeners are often added. Damping methods are described by M. W. Kellogg Co. (*Design of Piping Systems,* rev. 2d ed., Wiley, New York, 1965). For liquid phase pulsation damping, gas-filled surge chambers, also known as accumulators, are commonly used; see Wylie and Streeter (*Hydraulic Transients,* McGraw-Hill, New York, 1978).

Software packages are commercially available for simulation of hydraulic transients. These may be used to analyze piping systems to reveal unsatisfactory behavior, and they allow the assessment of design changes such as increases in pipe-wall thickness, changes in valve actuation, and addition of check valves, surge tanks, and pulsation dampeners.

Cavitation Loosely regarded as related to water hammer and hydraulic transients because it may cause similar vibration and equipment damage, **cavitation** is the phenomenon of collapse of vapor bubbles in flowing liquid. These bubbles may be formed anywhere the local liquid pressure drops below the vapor pressure, or they may be injected into the liquid, as when steam is sparged into water. Local low-pressure zones may be produced by local velocity increases (in accordance with the Bernoulli equation; see the preceding "Conservation Equations" subsection) as in eddies or vortices, or near boundary contours; by rapid vibration of a boundary; by separation of liquid during water hammer; or by an overall reduction in static pressure, as due to pressure drop in the suction line of a pump.

Collapse of vapor bubbles once they reach zones where the pressure exceeds the vapor pressure can cause objectionable noise and vibration and extensive erosion or pitting of the boundary materials. The critical cavitation number at inception of cavitation, denoted σ_i, is useful in correlating equipment performance data:

$$\sigma_i = \frac{p - p_v}{\rho V^2/2} \tag{6-207}$$

where p = static pressure in undisturbed flow
p_v = vapor pressure
ρ = liquid density
V = free-stream velocity of the liquid

The value of the cavitation number for incipient cavitation for a specific piece of equipment is a characteristic of that equipment. Cavitation numbers for various head forms of cylinders, for disks, and for various hydrofoils are given by Holl and Wislicenus (*J. Basic Eng.,* **83,** 385–398 [1961]) and for various surface irregularities by Arndt and Ippen (*J. Basic Eng.,* **90,** 249–261 [1968]), Ball (*Proc. ASCE J. Constr. Div.,* **89**(C02), 91–110 [1963]), and Holl (*J. Basic Eng.,* **82,** 169–183 [1960]). As a guide only, for blunt forms the cavitation number is generally in the range of 1 to 2.5, and for somewhat streamlined forms the cavitation number is in the range of 0.2 to 0.5. Critical cavitation numbers generally depend on a characteristic length dimension of the equipment in a way that has not been explained. This renders scale-up of cavitation data questionable.

For cavitation in flow through orifices, Fig. 6-55 (Thorpe, *Int. J. Multiphase Flow,* **16,** 1023–1045 [1990]) gives the critical cavitation number for inception of cavitation. To use this cavitation number in Eq. (6-207), the pressure p is the orifice backpressure downstream of the vena contracta after full pressure recovery, and V is the average velocity through the orifice. Figure 6-55 includes data from Tullis and Govindarajan (*ASCE J. Hydraul. Div.,* **HY13,** 417–430 [1973]) modified to use the same cavitation number definition; their data also include critical cavitation numbers for 30.50- and 59.70-cm pipes
